Fig. 24-23: Nifedipine-induced gingival enlargement.

Management

- *Surgical excision*—If hyperplasia interferes with function, surgical excision is recommended.
- *Discontinue the drug*—discontinuing the drug will result in gradual diminution of the bulk of the gingiva.

Combined Gingival Enlargement

In this type, enlargement of both inflammatory as well as fibrous component are present. It can be localized (Fig. 24-24) or generalized (Fig. 24-25).

Fig. 24-24: Localized combined gingival enlargement showing inflammatory and fibrous component.

Fig. 24-25: Generalized combined gingival enlargement.

Pregnancy-induced Gingival Enlargement

It can be marginal or generalized and may occur as a single or multiple tumors like masses.

Clinical Features

- *Marginal enlargement*—it tends to be more prominent interproximally, than on the facial and lingual surfaces. The enlarged gingiva is bright red or magenta, soft and friable and has a smooth shiny surface. Bleeding occurs spontaneously or on slight provocation.
- *Pregnancy tumor*—it is an inflammatory reaction to the local irritants. It usually appears after 3rd month of pregnancy.

- **Appearance**—the lesions appear as discrete, mushroom like (**Fig. 24-26**), flattened spherical masses, that protrude from the gingival margins or more frequently from the interproximal space and are attached by sessile or pedunculated base. It tends to expand laterally. The pressure from the tongue and the cheek perpetuates its flattened appearance.
- **Color**—it is generally dusky red or magenta; it has a smooth glistening surface that frequently exhibits numerous deep red, pinpoint markings.
- **Consistency**—the consistency varies from semifirm, but may have a varying degree of softness and friability.
- **Symptoms**—it is usually painless, unless its size and shape foster the accumulation of debris under its margin or interfere with occlusion, in which painful ulceration may occur.

Fig. 24-26: Mushroom like enlargement seen in pregnant women.

Diagnosis

- **Clinical diagnosis**—mushroom like enlargement in pregnancy will diagnose this condition.
- **Laboratory diagnosis**—the connective tissue consists of numerous, diffusely arranged, newly formed and engorged capillaries, lined by cuboidal endothelial cells. The epithelium exhibits some degree of intracellular or extracellular edema with prominent intercellular bridges and leukocytic infiltration.

Management

- **Maintenance of oral hygiene**—most gingival enlargement during pregnancy can be prevented by the removal of local irritants and institution of a fastidious oral hygiene.

Puberty-induced Gingival Enlargement

It is usually associated with inflammatory type.

Clinical Features

- **Age and sex**—it occurs in both, males and females in pubertal age group. It also appears in areas of local irritants.
- **Site**—it involves mainly the marginal gingiva and interdental gingiva.
- **Appearance**—it is characterized by prominent bulbous interproximal papillae (**Fig. 24-27**). Sometimes, only facial gingivae are enlarged, as the mechanical action of the tongue prevents heavy accumulation of local irritants on the lingual surface.

Fig. 24-27: Puberty-induced gingival enlargement showing prominent bulbous papillae.

Diagnosis

- **Clinical diagnosis**—bulbous enlargement at the onset of puberty will give clue to the diagnosis.
- **Laboratory diagnosis**—microscopic picture is that of chronic inflammatory cells with prominent edema and associated degenerative changes.

Management

- **Removal of local irritant**—after puberty, the enlargement undergoes spontaneous reduction, but does not disappear until local irritants are removed.

Necrotizing Ulcerative Gingivitis

It is an endogenous oral infection that is characterized by necrosis of gingiva. It is also called as 'Trench mouth' due to its prevalence in combat trenches (**Fig. 24-28**). Other synonyms for this are 'Vincent's infection', 'Acute ulceromembranous gingivitis', 'Fusospirochetal gingivitis' and 'Acute ulcerative gingivitis'. Tissue destruction is caused by endogenous organisms that act either on the tissue or, indirectly by triggering an inflammatory reaction.

Etiology

- *Role of bacteria*—it is caused by fusiform bacilli and spirochetes. In addition to it, bacteroides intermedius is also responsible for ANUG.
- *Local predisposing factors*—poor oral hygiene, pre-existing marginal gingivitis and faulty dental restorations. Deep periodontal pockets offered favorable environment for occurrence of the disease. Area of gingiva is traumatized by opposing maloccluded teeth. As tobacco smoke has a direct toxic effect on the gingiva, smoking and emotional stress can predispose for ANUG.
- *Systemic predisposing factors*
 - *Nutritional deficiency*—nutritional deficiency like vitamin C, vitamin B₂ accentuate the severity of the pathologic changes induced by the fusospirochetal bacterial complex.
 - *Debilitating disease*—chronic diseases like leukemia, aplastic anemia, syphilis, severe gastrointestinal disturbances and AIDS can act as predisposing factors.
 - *Marked malnutrition*—it may be predisposing factors to necrotizing ulcerative gingivitis.
 - *Psychosomatic factors*—the disease often occurs in association with a stress situation as well as with increase in adrenocortical secretion.

Clinical Features

- *Age*—it is most commonly seen in the age group of 16 to 30 years, but can be seen in children from a low socioeconomic group, in underdeveloped countries.
- *Symptoms*—onset is sudden with pain, tenderness, profuse salivation and peculiar metallic taste. Spontaneous bleeding from gingival tissue occurs. There is also a loss of sense of taste and diminished pleasure from smoking. The typical fetid odor ultimately develops, which may be extremely unpleasant.
- *Signs*—teeth seem slightly to be extruded and are sensitive to pressure or have a woody sensation. They are slightly movable and the patient is unable to eat properly. Gingiva may become superficially stained with brown color. There is blunting of interdental papillae (Fig. 24-28).
- *Appearance*—a typical lesion consists of necrotic punched out, crater like ulcerations are developed most commonly on the interdental papillae and marginal gingiva (Fig 24-29). Removal of the lesion leaves raw surface. The surface of gingival crater is covered by a gray, pseudo-membranous slough, demarcated from the remainder of the gingival mucosa by pronounced linear erythema. In some cases, ulceration may develop on cheek, lip, tongue, palate and pharyngeal area. If untreated, it may result in progressive destruction of the periodontium and

Fig. 24-28: Necrotizing ulcerative gingivitis showing blunting of interdental papilla.

denudation of the roots, accompanied by increase in the severity of complications.

- *Lymph nodes*—regional lymph nodes are enlarged.
- *Fever*—there may be a slight elevation of temperature.
- *Systemic complications*—in severe cases, there may be systemic complications like high fever, increased pulse rate, loss of appetite and generalized lassitude.

Fig. 24-29: Necrotizing ulcerative gingivitis showing ulceration of marginal gingiva.

Clinical Classification of NUG

- *Stage I*—only the superior margins of the interdental papillae are affected. There is marked tendency of bleeding on probing.
- *Stage II*—the process spreads to the marginal gingiva with characteristic punched out destruction.
- *Stage III*—the attached gingiva is affected in addition to the interdental papillae and marginal gingiva.
- *Stage IV*—the necrotizing process has resulted in denudation of bone.

Diagnosis

- *Clinical diagnosis*—punched out ulceration of gingiva with systemic features will give clue to the diagnosis.
- *Laboratory diagnosis*—the surface epithelium is destroyed and is replaced by a pseudomembranous meshwork of fibrin, necrotic epithelial cells, polymorphonuclear neutrophils and various types of microorganisms. The underlying connective tissue is markedly hyperemic with numerous engorged capillaries and a dense infiltration of PMN. Numerous plasma cells may appear in the periphery of infiltrate.

Differential Diagnosis

ANUG, presenting as an isolated phenomenon, must be differentiated from severe systemic diseases and in condition where acute inflammation of gingival and periodontal regions are the only associated symptoms.

- *Agranulocytosis*—blood picture shows evidence of a systemic disease and due to diminished immunity lesion is not marked by a severe inflammatory reaction.
- *Gingival changes due to cytostatic and immunosuppressive therapy*—history is relevant.
- *Benign mucus pemphigoid*—erosion, no necrosis and seen in elder adults.
- *Pemphigus*—it follows a chronic course with classical histological picture. It occurs in older patients and skin changes are seen.
- *Pemphigoid lichen planus*—no acute course, no bad breath, whitish changes and skin symptoms.
- *Gonococcal stomatitis*—the oral mucosa is covered with a grayish membrane that sloughs off in areas, to expose an underlying raw bleeding surface.
- *Syphilitic gingivitis*—primary lesion seldom on gingiva, does not spread to neighboring surfaces.
- *Gingivostomatitis due to Candida*—whitish deposits that can be wiped off, no bad breath, less acute picture and demonstration of fungi.
- *Tubercular ulcer*—less acute picture.
- *Streptococcal gingivostomatitis*—it is characterized by a diffuse erythema on the posterior areas of the oral mucosa. But in these cases, necrosis of gingiva is not a feature.

Management

- *Removal of pseudomembrane*—the involved areas are isolated with cotton rolls and dried. A topical anesthetic is applied and after 2 to 3 minutes, the areas are gently swabbed with a cotton pellet to remove the pseudomembrane and nonattached surface. After the area is cleansed with warm water, the superficial calculus is removed.

Table 24-3: Herpetic gingivostomatitis

ANUG	Acute herpetic gingivostomatitis
Etiology—interaction between host and bacteria, most probably fusospirochetal	Specific viral etiology
Necrotizing condition	Diffuse erythema
Punched out gingival margins, pseudomembrane that peels off leaving raw areas, marginal gingiva affected	Vesicle ruptures and leave a slight depression or an oval or a spherical ulcer
Rare in children	Occurs most frequently in children
No definite duration	Duration of 7 to 10 days

Table 24-4: Difference between ANUG, diphtheria and secondary stage of syphilis

ANUG	Diphtheria	Secondary stage of syphilis
Caused by fusospirochetes	Caused by corynebacterium diphtheriae	Caused by treponema pallidum
Affect marginal gingiva	Rarely affects the marginal gingiva. It affects the throat, fauces and tonsil	Rarely affects marginal gingiva. Any site of the oral cavity can be affected
Membrane removal easy	Membrane removal difficult	Membrane not detachable
Painful condition	Less painful	Minimal pain
Serological findings are normal	Serological findings are normal	Serological findings are abnormal
Doubtful contagiousity	Contagious	Only direct contact can cause this disease

- *Rinsing the mouth*—the patient is asked to rinse the mouth within every 2 hours, with a glassful of an equal mixture of warm water and 3% hydrogen peroxide. Twice daily rinse with 0.12% chlorhexidine are also effective.
- *Antibiotics*—patients with severe ANUG and lymphadenopathy are treated with antibiotics Penicillin V- 250 or 500 mg, 6 hourly or erythromycin—250 or 500 mg, 6 hourly with metronidazole 400 mg, 8 hourly, for 7 days are the drugs of choice.
- *Gingival curettage*—scaling is performed, if sensitivity permits. After the disease process is diminished, complete gingival curettage and root planning is done.
- *Supportive treatment*—supportive treatment consists of copious fluid consumption and administration of nutritional supplements.

Non-plaque-induced Gingival Disease

Bacterial Origin Gingival Disease

- **Mechanisms**—in rare occasions, when non-plaque related microorganisms override the host's innate immunity, infective gingivitis and stomatitis may occur in immunocompromised or non-immunocompromised individuals.
- **Organism responsible**—such infections may be caused by *Neisseria gonorrhoea*, *Treponema palladium*, *Streptococci*, *Mycobacterium chelonae* or other microorganisms.
- **Appearance**—the lesions manifest as fiery red, edematous, painful ulcerations, as asymptomatic chancres or mucus patches, or as atypical non-ulcerated, highly inflamed gingivitis. Biopsy supplemented by microbiologic examination reveals the underlying etiology.

Viral-induced Gingival Disease

Herpetic Gingivostomatitis

- **Mechanism**—herpes simplex virus has a low infection potential. Hence, after gaining entry into the oral mucosa it penetrates a neural ending and travels to trigeminal ganglion through smooth endoplasmic reticulum and remains latent for years. The virus has also been isolated from normal gingiva, gingivitis, acute necrotizing gingivitis and periodontitis cases.
- **Appearance**—the clinical features of primary herpetic gingivostomatitis include painful, severe gingivitis with redness, ulcerations with serofibrinous exudates and edema accompanied by stomatitis. In its initial stage, it is characterized by the presence of discrete spherical gray vesicles which may occur on the gingiva, labial and buccal mucosa; soft palate, pharynx, sublingual mucosa and tongue. After approximate 24 hours, the vesicles rupture and form painful small ulcers with a red elevated halo-like margin and a depressed yellowish or grayish-white central portion. This occurs in widely separated areas or in clusters where confluence occurs. Fever and lymphadenopathy are common. The incubation period is one week. Healing of ulcers occur spontaneously without scarring in 10-14 days. During the course of the disease, the generalized soreness of oral cavity interferes with eating and drinking.
- **Management**—the treatment includes careful plaque removal to limit bacterial superinfection, which delays the healing. In severe cases, including patients with immunodeficiency, systemic use of antiviral drugs such as acyclovir or valacyclovir is recommended.

Herpes Zoster

- **Organism**—varicella-zoster virus causes varicella (chickenpox) as the primary self-limiting infections which occur mainly in children and later activation of the virus in adults causes herpes zoster (shingles).
- **Appearance**—the intraoral ulcers usually involves gingiva, tongue and palate. The diagnosis is generally obvious due to unilateral occurrence of the lesions associated with severe pain. Healing of lesions take place in 1-2 weeks.
- **Management**—treatment consists of soft or liquid diet, rest, atraumatic removal of plaque and diluted chlorhexidine rinses. This may be supplemented by antiviral drug.

Gingival Disease of Fungal Origin

- **Candidiasis**—the most common intraoral fungal infection is candidiasis which is caused by *Candida albicans*, the proteinase-positive strain. It usually occurs as a consequence of reduced host defense, reduced salivary secretion, smoking and treatment with corticosteroids and broad-spectrum antibiotics. The most common clinical characteristics of gingival candidial infection is redness of the attached gingiva often associated with a granular surface. A diagnosis of the candidial infection can be done on the basis of culture, smear and biopsy. Topical treatment involves application of antifungal, nystatin, amphotericin B or miconazole.
- **Linear gingival erythema**—it is regarded as gingival manifestation of immunosuppression characterized by a distinct linear erythematous band limited to free gingiva. There is no attachment loss or pocket formation and the lesion does not respond to conventional plaque control methods and improved oral hygiene.
- **Histoplasmosis**—it is a granulomatous disease caused by *Histoplasma capsulatum*. The clinical manifestations include acute or chronic pulmonary histoplasmosis. The oral lesions are initiated as nodular or papillary and later may become ulcerative, painful with the loss of gingival tissue. They are sometimes granulomatous and the clinical appearance may resemble a malignant tumor. The diagnosis is based on clinical appearance, histopathology and/or culture.

Gingival Manifestations of Systemic Condition

- **Mucocutaneous disorders**—many mucocutaneous disorders may manifest intraorally in the form of desquamative lesions and ulcerations of gingiva (Fig. 24-31). The most important of these are lichen planus (Fig. 24-30), pemphigoid, pemphigus vulgaris, erythema multiforme and lupus erythematosus. Certain conditions

Fig. 24-30: Desquamative gingivitis present due to lichen planus.

Fig. 24-31: Ulceration of gingiva seen in desquamative type of gingivitis associated with dermatological disorders.

may also present themselves as desquamative gingivitis. These are factitious injuries, graft versus host disease, Wegener's granulomatosis, foreign body gingivitis, Kindler syndrome and squamous cell carcinoma.

- **Allergic reaction**—allergic reactions in the oral mucosa are uncommon. These reactions are type I (immediate type), which is mediated by IgE, or more often type IV (delayed type) mediated by T cells. The uncommon occurrence of these reactions intraorally may be due to the fact that much higher concentration of allergens is required for an allergic reaction to occur in the oral mucosa than in skin. The allergic reactions can be further classified on the basis of the type of allergen: Reactions due to dental restorative materials and reactions due to oral hygiene products, food and chewing gum.
- **Hematological disorders**—hematological disorders like leukemia may also manifest intraorally. Gingival manifestations in leukemia which includes extensive swelling, ulceration, petechiae and erythema are common in acute than in chronic forms. The pronounced gingival swelling is due to leukemic infiltration and

plaque-induced inflammation. Spontaneous gingival bleeding is also a common symptom of leukemic patients which develops secondary to thrombocytopenia. The primary concern is prevention of infection and bleeding. Careful and strict oral hygiene measures can reduce gingival inflammation. In some cases of iron deficiency anemia, gingival enlargement can occur.

Fig. 24-32: Enlargement of gingiva seen in iron deficiency anemia.

Gingival Recession

Types of Gingival Recession (By Miller)

- **Class I**—marginal tissue recession not extends to the mucogingival junction. There is no loss of interdental bone or soft tissue.
- **Class II**—marginal tissue recession that extends to or beyond the mucogingival junction, there is no loss of bone or soft tissue in the interdental area (Fig. 24-33).

Fig. 24-33: Class II gingival recession.

- **Class III**—marginal tissue recession that extend to or beyond the mucogingival junction in addition, there is loss bone and/or soft tissue in the interdental area or there is malpositioning of the teeth (Fig. 24-34).

Fig. 24-34: Class III gingival recession.

- *Class IV*—marginal tissue recession that extends to or beyond the mucogingival junction with severe loss of soft tissue or bone interdentally and/or severe malpositioning of the teeth (Fig. 24-35).

Fig. 24-35: Type IV gingival recession.

Traumatic Lesion of Gingiva

- *Chemical injury*—chemical injury due to various agents have been noticed. Chlorhexidine induced mucosal desquamation, acetylsalicylic acid burn (aspirin burn), cocaine burn, sloughing of mucosa due to dentifrice detergents, necrosis of gingiva due to use of para-formaldehyde are examples of it.
- *Physical injury*—physical injury to gingiva may occur due to heavy brushing forces; high abrasive of dentifrice and horizontal movement of brushing. Overzealous brushing can also produce damage to interdental papilla.
- *Factitious injury*—factitious injuries leading to gingival recession can produce because of picking at or

scratching of the gingiva with fingernail or pins, oral piercing or overzealous use of tooth pick.

- *Thermal injury*—extensive thermal burns may occur to oral mucosa especially palatal and labial mucosa due to hot beverages, pizza, melted cheese. The lesions may be painful, erythematous or with a slough coated surface. Vesicles may also form and sometimes may present as ulceration, petechiae or erosion.

Foreign Body Reaction

Another type of tissue reaction is observed when foreign materials are embedded in the gingival connective tissue due to epithelial ulceration. The common example is amalgam tattoo. Sometimes, chewing on sticks can introduce piece of stick in the gingiva producing an inflammatory reaction.

Carcinoma of the Gingiva

It is most commonly seen squamous cell carcinoma and occurs due to habits of tobacco.

Clinical Features

- *Age*—it is common in 5th and 6th decades of life.
- *Site*—the carcinoma of mandibular gingiva is more common than the involvement of the maxillary gingiva. The tumor arises most commonly in an edentulous area, although it may develop in a site where teeth are present. The fixed gingiva is involved more than the free gingiva. It usually occurs in premolar-molar area. In maxilla, gingival carcinoma often invades maxillary sinus or it may extend to palate or tonsillar pillars.
- *Appearance*—it is manifested as an area of ulceration, which may be a purely erosive lesion and may exhibit as an exophytic, granular or verrucous type of growth.
- *Symptoms*—in some patients, the first symptom may be loosening of the teeth.
- *Invasion*—quickly spreads from the gingiva to alveolar bone below. The proximity of the underlying periosteum and bone usually invites early invasion of these structures (Fig. 24-36).

Radiographic Features

- *Types*—there are, radiologically, three types of bone destruction, i.e. permeated type, moth eaten type and pressure type.
 - *Permeated type*—bone destruction with ill-defined margins. Permeated means permeation of water into sand, with ragged ill-defined borders. It also destroys the mandibular canal.
 - *Moth eaten type*—it resembles moth eaten image with remnants of bony fragments.

Fig. 24-36: Carcinoma of gingiva which is extending toward buccal mucosa (Courtesy Dr Suwas Darvekar).

- *Pressure type*—dish out concavity appearance with relatively smooth margins.
- *Rarefaction*—rarefaction with remnants of small bony fragment.
- *Cortical bone destruction*—cortical bone destruction with pathologic fractures also can occur.

Diagnosis

- *Clinical diagnosis*—ulcerative growth on the gingiva with history of tobacco habit may give clue to the diagnosis.
- *Radiological diagnosis*—comparison between periodontitis and carcinoma of gingiva is described below in **Table 24-5**.
- *Laboratory diagnosis*—biopsy show features suggestive of squamous cell carcinoma.

Table 24-5: Comparison between periodontitis and carcinoma of gingiva

Features	Periodontitis	Carcinoma of gingiva
Margin of bone resorption	Smooth and well defined	Infiltrative and ill-defined
Sclerotic bony findings	Exist, around the margin of the lesion	No sclerotic finding
Residual small bony fragments	None within the lesion	Exist in most of the cases
Size	The condition is usually generalized and if localized, there is a specific cause for it	Localized finding

Management

- *Surgery*—localized lesions, of less than 3 cm in diameter, were cured in 80% of the cases by surgical excision.

Periodontal Disease

Periodontitis is defined as an inflammatory disease of the supporting tissues of the teeth caused by specific microorganism resulting in progressive destruction of the periodontal ligament and alveolar bone with pocket formation, recession or both.

The clinical feature that differentiates periodontitis from gingivitis is presence of clinically detectable attachment loss. The clinical classification was simplified to describe the three general clinical manifestations of periodontitis: chronic periodontitis, aggressive periodontitis and periodontitis as a manifestation of systemic disease.

Etiology of Periodontal Diseases

- *Multifactorial*—multifactorial, resulting from various hosts and environmental factors.
- *Open contact*—when teeth are not in contact, the patient is said to have open contact. It is dangerous for the periodontium as food debris may trap in it and hence more bone loss occurs, than the areas of closed contact.
- *Microorganisms*—plaque forming bacteria play a role in initiation and progression of destruction of the periodontium, mainly the anaerobic bacteria. When bacteria colonize at the root surface, they spread in the region between the root and gingival margins and stimulate a chronic inflammatory reaction. It results in pocket formation and apical migration of the epithelial attachment and bone loss.
- *Immune system*—Neutrophils, granulocytes and monocytes are very important in causing destruction of the bacteria and thus, preventing periodontitis. It may, sometimes, release lymphocytes and cause microbial destruction.
- *Secondary local factors*—like calculus deposits (**Fig. 24-37**), carious cavities, overhanging margins, perforation by pins or posts, over erupted opposing teeth and gingivally impinging partial dentures.

Fig. 24-37: Heavy calculus seen in upper posterior region.

Pathogenesis of Periodontitis

It is an inflammation of the supporting structures of the teeth. It starts out as gingivitis that then spreads down to the root surface causing alveolar bone resorption and pocket formation. It can eventually lead to alveolar bone loss and damage to the periodontal ligament then can result in tooth loss. Other complications include periodontal abscess and osteomyelitis of the jaws.

Periodontal Pockets

Classification

- *Gingival pocket (relative or false)*—it is formed by gingival enlargement, without destruction of the underlying periodontal tissues. The sulcus is deepened because of the increased bulk of the gingiva (**Fig. 24-38**).
- *Periodontal pocket (absolute or true)*—there is destruction of the supporting periodontal tissue; progressive pocket deepening leads to destruction of the supporting periodontal tissues and loosening and exfoliation of the teeth.
- *Suprabony pocket (supracrestal or supra-alveolar)*—in it, bottom of the pocket is coronal to the underlying alveolar bone.
- *Infrabony (intrabony, subcrestal or intra-alveolar)*—in it, bottom of the pocket is apical to the level of the adjacent alveolar bone.

Fig. 24-38: Gingival pocket seen due to enlargement of gingiva.

Pathogenesis

- *Microorganism*—periodontal pockets are caused by microorganisms and their products, which produce pathologic tissue changes that lead to the deepening of the gingival sulcus.
- *Inflammatory changes*—pocket formation starts as an inflammatory changes in the connective tissue wall of the gingival sulcus.

- *Degeneration of connective tissue*—the cellular and fluid inflammatory exudates cause degeneration of the surrounding connective tissues, including the gingival fibers.
- *Destruction of collagen fibers*—just apical to the junctional epithelium, an area of destroyed collagen fibers develops and becomes occupied by inflammatory cells and edema. Collagen loss may occur due to enzymes, like collagenase and other lysosomal enzymes from polymorphonuclear leukocytes and macrophages, which become extracellular and destroy the collagen.
- *Proliferation of junctional epithelium*—as a consequence of loss of collagen, the apical portion of the junctional epithelium proliferates along the root, extending in finger-like projections.
- *Detachment of junctional epithelium*—as the apical portion migrates, the coronal portion of the junctional epithelium detaches from the root. As a result of inflammation, polymorphonuclear neutrophils invade the coronal end of junctional epithelium. An increase in number of these cells, results in loss of tissue cohesiveness and tissue detachment from the tooth surface. Thus, the bottom of the sulcus shifts apically, resulting in deepening of the periodontal pocket.

Clinical Features

- *Signs*—gingival bleeding or/and suppuration, tooth mobility and Diastema formation may be present. In some cases, pus may be expressed by applying digital pressure.
- *Symptoms*—patient may complain of localized pain or deep pain in the bone. When explored with a probe, the inner aspect of the periodontal pocket is generally painful.
- *Color*—there may be bluish red, thickened marginal gingiva and a bluish red vertical zone from the gingival margin to the alveolar mucosa.

Radiographic Findings

- *Use of gutta percha point*—pockets are not detected on radiograph as they are soft tissue changes. Gutta percha points or calibrated silver points can be used, with a radiograph, to assist in determining the level of attachment of the periodontal pocket.

Diagnosis

- *Clinical diagnosis*—this can be made with the help of periodontal probe (**Fig. 24-39**).
- *Radiological diagnosis*—it is made with the help of gutta percha point.
- *Laboratory diagnosis*—there may be circulatory stagnation, destruction of the gingival fibers and surrounding tissues, which results in discoloration.

Fig. 24-39: Periodontal pocket is examined with the help of periodontal probe.

Management

- *Pocket irrigation*—devices like squeeze bottles and blunt hypodermic needles can be used to irrigate the pocket with chemotherapeutic agents.
- *Flap surgery*—it is done to eliminate pockets.

Periodontal Abscess

It is usually culmination of a long period of chronic periodontitis.

Pathogenesis

- *Pre-existing periodontal pocket*—it usually occurs in pre-existing periodontal pocket. When such pocket reaches sufficient depth of about 5 to 8 mm, the soft tissues, around the neck of the tooth may approximate the tooth so tightly that orifice of the pocket is occluded.
- *Multiplication of bacteria*—bacteria multiply in the depth of pocket and cause sufficient irritation to form an acute abscess, with exudation of pus into this area. It results in sufficient swelling to destroy the cortical plates of bone.

Clinical Features

- *Location*—it starts at the gingival crevice and extends down on one or more surface of the root, frequently as far as apical region.
- *Symptoms*—acute episode usually has sudden onset with extreme pain. There is also distension and discomfort.
- *Signs*—they are associated with swelling of the soft tissues overlying the surface of the involved root (**Figs 24-40A and B**). Tooth is tender and mobile. Pus usually exudes from the gingival crevice.

Figs 24-40A and B: Periodontal abscess showing swelling at the periapical region.

Diagnosis

- *Clinical diagnosis*—severe pain with swelling in the apical region will give clue to the diagnosis.
- *Laboratory diagnosis*—there is central cavity filled with pus walled off on one side by the root and on the other side by connective tissue.

Management

- *Analgesic and antibiotics*—suitable analgesics and antibiotics should be given to patient.
- *Incision and drainage*—primary treatment for relief of acute symptoms is incision of the fluctuant abscess, from the depth of the abscess cavity to the gingiva. The incision should extend into the soft tissues of the root surface.
- *Debridement of root surface*—if the surrounding tissue are normal, the tooth may be retained and debridement of the root surface by removal of granulation tissue should be done. Treatment for new attachment and new tissue regeneration should be performed.

- *Extraction of tooth*—however, if the roots are denuded beyond the apical thirds of the root, the tooth should be extracted and curettage should be carried out to remove the granulation tissue from the socket.

Chronic Periodontitis

It is the most common form of periodontitis and is most prevalent in adults but can also be observed in children. It is generally a slowly progressive form of periodontitis which at any stage may undergo acute exacerbation with associated attachment loss. The clinical features are gingival inflammation, bleeding on probing, reduced resistance of the periodontal tissues to probing, loss of clinical attachment and loss of alveolar bone. Variable feature includes gingival enlargement, recession of gingiva, furcation involvement, increased tooth mobility, drifting of teeth and eventually exfoliation of teeth.

Chronic periodontitis is subject related with only a few individuals experiencing advanced destruction, affects specific teeth and the progression of inflammatory disease is continuous with brief episodes of localized exacerbation and occasional remission.

Classification

It is classified according to extent and severity of diseased sites

- *According to extent of disease:*
 - *Low*—1 to 10 sites.
 - *Medium*—11 to 20 sites
 - *High*—Greater than 20 sites.
- *According to severity*—this can be differentiated to the degree of clinical attachment loss.
 - *Mild*—1-2 mm clinical attachment loss.
 - *Moderate*—3-4 mm clinical attachment loss.
 - *Severe*—more than 5 mm clinical attachment loss (Fig. 24-41).

Fig. 24-41: Generalized severe chronic periodontitis.

Etiology

Many risk factors have been associated with initiation of chronic periodontitis or once contracted then the progression of the disease.

- *Microbial plaque*—it is a crucial factor in inflammation of the periodontitis is largely governed by host-based risk factors.
- *Age*—the prevalence of periodontitis increase with age as a result of cumulative effects of disease over a lifetime.
- *Smoking*—smoking has been positively associated with progression of periodontitis. The risk attributed to tobacco for chronic periodontitis is between 2.5 and 7.0. It is not only the risk for developing the disease, but also the response to periodontal therapy is impaired to smokers.
- *Host-related factors*—
 - *PMN*—reduction in number and/or function of PMNs.
 - *Drugs*—drugs like Phenytoin, nifedipine and cyclosporine predispose to gingival overgrowth and thus may modify preexisting chronic periodontitis.
 - *Hormones*—changes in circulating hormones during pregnancy, puberty, and menopause can modify gingival response to plaque.
 - *Immunosuppressant drug therapy*—immunosuppressant drug therapy and any disease resulting in suppression of inflammatory and immune processes (such as HIV infection) may predispose the individual to periodontal tissue destruction.
 - *Nutritional deficiency*—nutritional deficiencies in animals have shown effects on periodontal tissues but have been proven in human studies. Vitamin C deficiency has been consistently associated with increased gingival bleeding.
 - *Diabetes mellitus*—periodontitis severity goes hand in hand with poorly controlled diabetes mellitus. On the other hand, periodontitis may also exacerbate diabetes as it may decrease glycemic control.
 - *Psychogenic disorders*—stress and other psychosomatic disorders may have direct anti-inflammatory and/or immunosuppressive effects which are relevant to the etiology of chronic periodontitis and necrotizing ulcerative gingivitis.
 - *Genetic*—gingivitis is a general and ubiquitous response to plaque accumulation whereas risk of chronic periodontitis has a high inherited component. The focus of researcher is on the polymorphisms associated with genes involved in cytokine production. An increased risk for chronic periodontitis has been associated with polymorphisms of genes involved in cytokines production but these findings are yet to be confirmed.

Clinical Features

- *Age and sex*—it generally affects both the sexes equally and is seen in older age groups more frequently.
- *Site*—it is usually generalized, although some areas may be involved more deeply than others.
- *Symptoms*—it is usually painless, but sometimes exposed root may be sensitive to heat and cold, in absence of caries. Areas of localized deep pain, sometimes radiating deep into the jaws are established.
- *Signs*—the characteristic finding in it, is gingival inflammation, which results from accumulation of plaque and loss of periodontal attachment. The gingiva is slightly or moderately swollen and exhibits alteration in color from pale to magenta. There is also loss of stippling and gingival bleeding, which may be either spontaneous or easily provoked.
- *Pocket formation*—there is presence of pocket with variable pocket depth. Both, horizontal and angular bone loss can be found (Fig. 24-42).

Fig. 24-42: Chronic periodontitis showing pocket formation.

- *Tooth mobility*—tooth mobility is found in advanced cases, where bone loss has been considerable. Teeth give off a rather dull sound when tapped with a metal instrument. The embrasures may be opened because the interdental papillae are deficient.
- *Gingival recession*—gingival recession is a common phenomenon in later stages of disease, which may expose the cementum (Fig. 24-43).

Radiological Features

- *Bone resorption*—there is blunting of the alveolar crest due to beginning of bone resorption. Bone loss may occur horizontally, vertically (Fig. 24-44) or sometimes, in furcation area.

Fig. 24-43: Gingival recession seen in lower anterior region due to periodontal problems.

Fig. 24-44: Severe horizontal and vertical bone loss seen in chronic periodontitis.

- *Loss of interdental bone*—loss of corticated interdental crestal margin, the bone edges become irregular or blunted (Fig. 24-45).
- *PDL space widening*—widening of the periodontal ligament space and localized or generalized loss of alveolar supporting bone.
- *Floating teeth appearance*—in case of severe periodontitis, floating teeth appearance is seen (Fig. 24-46).

Fig. 24-45: OPG of chronic periodontitis showing bone loss.

Fig. 24-46: Floating teeth appearance seen in periodontitis.

Diagnosis

- *Clinical diagnosis*—gingival recession, pocket formation with mobility of tooth will diagnose the condition.
- *Radiological diagnosis*—horizontal and vertical bone loss is present.
- *Laboratory diagnosis*—the enlarged free marginal gingiva is densely infiltrated with lymphocytes and plasma cells. The apical borders of the inflamed area approach the crest of the alveolar bone and the crestal fibers of the periodontal ligament.

Management

- *Oral prophylaxis*—scaling and curettage can be done.
- *Flap surgery*—this is the treatment of choice.

Aggressive Periodontitis

Aggressive Periodontitis is a group of diseases which was previously defined on the basis of age of onset and was hence named early onset periodontitis. But at the 1999 international classification workshop has clubbed a group

of rare, often severe, rapidly progressive forms of periodontitis, often characterized by early age of clinical manifestation and a distractive tendency for cases to aggregate in families, under a common heading of Aggressive Periodontitis.

Etiology and Pathogenesis

- *Virulent microbial infection*—the shorter duration of time over which a clinical manifestation of the disease is seen suggests a highly virulent microbial infection or a highly susceptible host, or a combination of both.
- *Microorganism*—many studies have demonstrated that the prevalence of *Actinobacillus actinomycetem comitans* predominantly in localized aggressive periodontitis (Previously called localized juvenile periodontitis) with other microorganisms such as *Capnocytophaga*, *Eikenella corrodens*, *Prevotella intermedia* and motile anaerobes such as *Campylobacter rectus*. Gram positive isolates of streptococci, peptostreptococci and Actinomycetes were also obtained. Generalized Aggressive periodontitis, formerly named as early-onset periodontitis and rapidly progressive periodontitis, have been frequently associated with the presence of *Porphyromonas gingivalis*, *Bacteroides forsythus* and *actinobacillus actinomycetem comitans*.
- *Host response*—an intense infiltration of polymorphonuclear neutrophils underlines the importance of these cells in the local defense against bacterial aggression and their potential role in host mediated tissue destruction. B-cell and plasma cells form the mononuclear defense cells. Plasma cell dominantly produce IgG and in less amount IgA. The IgG is actively present in GCF which forms a line of defense against initial bacterial invasion. Peripheral blood mononuclear cells of AgP patients may demonstrate reduced autologous mixed lymphocytes reactions, as well as a higher than normal response to B-cell mitogen. A high level of PGE2 and IL-1beta is observed in AgP patients. It has been demonstrated that T-helper cells are depressed in numbers compared to T-suppressor cell. Elevated level of antibodies specific to AgP-associated microorganisms have been found in crevicular fluid than in peripheral blood. An important findings in LAP and GAP patients have been decreased migration and function of PMNs. These abnormalities are usually minor in sense that they usually are not associated with infection other than periodontitis. These abnormalities in PMNs have been found to have familial aggregation. Other recent reports contradict suggest hyper-inflammatory state resulting in high levels of serum pro-inflammatory cytokines in AgP patients (Autosomal dominant).

Characteristic of Aggressive Periodontitis

- **Primary features**—aggressive Periodontitis was characterized by following major common features
 - *Medical history*—non-contributory medical history.
 - *Rapid loss*—rapid attachment loss and bone destruction.
 - *Familial aggregation*—familial aggregation of cases.
- **Secondary features**—these are considered to be general but not universally present are:
 - *Microbial deposit*—amount of microbial deposit inconsistent with the severity of periodontal tissue destruction.
 - *Levels of actinobacillus*—elevated levels of Actinobacillus Actinomycetem comitans and in some Far East populations, Porphyromonas gingivalis.
 - *Phagocytic abnormalities*—phagocytic abnormalities are common in this type of periodontitis.
 - *Hyper-responsive macrophage*—hyper-responsive macrophage phenotype, including elevated production of PGE2 and IL-1 beta in response to bacterial endotoxins.
 - *Self-arresting attachment loss*—progression of attachment loss and bone loss may be self-arresting.

Classification

Aggressive Periodontitis was sub-classified at the international workshop into localized and generalized forms. The following were the observed features:

- **Localized aggressive periodontitis (LAP):**
 - Circumpubertal onset.
 - Localized first molar/incisor presentation with interproximal attachment loss on at least two permanent teeth, one of which is first molar and involving no more than two teeth other than first molars and incisors.
 - Robust serum antibody response to infecting agents.
- **Generalized aggressive periodontitis (GAP) (Fig. 24-47):**
 - Usually affecting persons under 30 years of age, but patients may be older.
 - Generalized interproximal attachment loss affecting at least three permanent teeth other than first molar and incisors.
 - Pronounced episodic nature of the destruction of attachment and alveolar bone.
 - Poor serum antibody response to infecting agents.

It is important to underline that, in the present state of uncertainty regarding both the causative agents and the genetic and environmental susceptibility to Aggressive periodontitis; it is possible that LAP and GAP may simply represent phenotypic variations, of a single disease entity. Conversely, it is possible that different Aggressive periodontitis forms may manifest themselves with a

Fig. 24-47: Generalized type of aggressive periodontitis.

common clinical presentation. This aspect is of great diagnostic and therapeutic importance.

Clinical Features

- **Age**—the age of onset of the disease ranges from the middle to late teens and till 30 years of age
- **Site**—the lesions are more generalized and all or most of the teeth are affected, without any definite pattern of distribution.
- **Signs**—gingiva is acutely inflamed, often proliferated, ulcerated and fiery red (Figs 24-48A and B). Bleeding may occur spontaneously, or on slight provocation. In some cases, gingiva appears pink and free of inflammation; but in spite of this, deep pockets can be revealed on probing.
- **Systemic features**—some patients may have systemic manifestations like weight loss, mental depression and general malaise.

Diagnosis

- **Clinical diagnosis**—rapid loss of periodontal structure with systemic features may suspect this disease.

Management

- **Antibiotics**—if microflora contains gram-positive microorganisms, then it should be treated with 250 mg amoxicillin and 125 mg potassium clavulanate three times daily, for 14 days, along with scaling and root planning. If flora is gram-negative, then clindamycin should be given with dose of 150 mg, four times a day, for 7 days, along with scaling and root planning.

Prepubertal Periodontitis

It is a very rare condition which starts during, or immediately after the eruption of primary teeth. There are functional defects of neutrophils and monocytes. It is transmitted as an autosomal recessive trait. It is associated with Papillion-Lefevre syndrome.

Figs 24-48A and B: Aggressive periodontitis showing gingival recession and inflammation with loss of attachment.

- *Generalized form*—in the generalized form, inflammation is extremely acute and destruction of gingiva and alveolar bone is very rapid. Leukocytosis, otitis media, skin and upper respiratory infection may also be present. The disease involves all the primary teeth (**Fig. 24-49**) and may or may not involve the permanent dentition. It is refractory to antibiotic therapy.
- *Localized form*—in it, only few teeth are affected. Gingiva may appear normal. The progress of disease is slow. Otitis media is an infrequent finding. The disease responds to scaling and antibiotic therapy.

Necrotizing Ulcerative Periodontitis

It occurs after repeated, long-term episodes of necrotizing ulcerative gingivitis. It can be associated with AIDS. Inflammatory infiltrate in the lesions of ANUG can extend to the underlying bone, resulting in a deep crater like osseous lesion most often located in the interdental area

Fig. 24-49: Prepubertal periodontitis showing involvement of primary teeth.

(**Fig. 24-50**). There is a presence of deep interdental osseous crater but deep conventional pockets are not found, because the ulcerative and necrotizing character of the gingival lesion destroys the junctional epithelium the removing the mechanism of pocket deepening. Ulceration is frequent finding in this type of periodontitis.

As the patients have underlying predisposing factors, it should be treated in consultation with a physician. Medical evaluation and local, topical and systemic antimicrobial should be given, based on the result of laboratory tests.

Fig. 24-50: Ulcerative periodontitis present in lower anterior region.

Tooth Mobility

Tooth has a slight degree of physiologic mobility, which varies from different teeth and at different times of the day. Mobility beyond the physiologic range is termed as abnormal or pathologic mobility.

Causes

- *Trauma from occlusion*—it usually results in mobility of the teeth. It occurs initially as result of resorption of the cortical layer of bone leading to a reduced fiber support and later, to adaptation phenomenon, resulting in a widened periodontal space.
- *Loss of tooth support*—it can result in mobility. The amount of mobility depends upon the severity and distribution of bone loss.
- *Inflammation*—extension of inflammation from the gingiva or periapical region, into the periodontal ligament, may increase tooth mobility.
- *Periodontal surgery*—it temporarily increases tooth mobility for a short period.
- *Systemic disease*—some systemic diseases can cause increased tooth mobility, like in pregnancy due to physicochemical changes in the periodontal tissues.
- The destruction of surrounding alveolar bone, such as in osteomyelitis or jaw tumor, may also increase tooth mobility.

Radiographic Features

- *PDL space widening*—there is a widening of periodontal ligament space and a single root may develop an hourglass shape. In multi-rooted teeth widening of periodontal ligament space at apices and in region of furcation is seen.
- *Angular bone loss*—bone loss which surrounds the tooth is also present (**Fig. 24-51**).

Fig. 24-51: Angular bone loss present in mobility.

Papillion-Lefevre Syndrome

It is an autosomal recessive and inherited disorder. It is a triad of:

- Hyperkeratosis of palms of the hand and soles of feet (**Fig. 24-52A**).

- Extensive prepubertal destruction of the periodontal bone supporting the dentition (**Fig. 24-52B**), usually extensive generalized horizontal bone loss.
- Calcification of dura.

Figs 24-52A and B: Papillion-Lefevre syndrome showing hyperkeratosis of palms with severe destruction of periodontium.

Clinical and Radiological Features

- *Hyperkeratosis*—there is reddened, scaly, rough palms and soles.
- *Periodontal finding*—It usually begins after eruption of the primary second molars. There is inflamed gingiva and horizontal bone destruction. Loss of entire primary dentition by the age of 5 years and loss of secondary dentition by the age of 20 years. Gingival swelling and severe halitosis.
- *Radiological features*—calcification of dura is seen in radiograph. Periodontal bone destruction is also present.

Diagnosis

- *Clinical diagnosis*—clinical diagnosis is suspected when hyperkeratosis of palm is seen in association with periodontal destruction.
- *Radiological diagnosis*—calcification in dura can be detected radiologically.
- *Laboratory diagnosis*—there is marked chronic inflammation of the lateral walls of the pocket, with predominantly plasma cell infiltrate, considerable osteoclastic activity and apparent lack of osteoblastic activity.

Management

- *Periodontal management*—flap surgery, oral prophylaxis should be done.

Radiological Assessment of Periodontal Diseases

Bone loss can be defined as a difference between the present septal bone height and the assumed normal bone height for any particular patient, bearing in mind that the normal bone height varies with age. The main radiographic projections used for periodontal diseases are bitewing, paralleling line angle periapical technique, digital radiography and dental panoramic tomography.

Advantages of Radiography in Periodontal Diseases

- *Identification of causative factors*—often valuable in identifying local initiating factors like calculus, poorly contoured or over extended restorations.
- *Status of periodontium*—to know the status of the periodontium such as root length and morphology, crown-root ratio, condition of the alveolar bone around the root and position of the maxillary sinus in relation to periodontal deformities.
- *Amount of bone present*—it offers the clinician to overview of the amount of bone present and serves as a permanent record of the condition of bone throughout the course of the disease.
- *Treatment outcome*—to evaluate treatment measures, particularly following guided tissue regeneration.

Limitations of Radiography

- *Overlapping*—inability of the viewer to perceive bony defects that are overlapped by existing bony walls.
- *Mild lesion*—earliest mild destructive lesions in the bone do not cause sufficient alteration in the density to be detectable.
- *Root superimposition*—density of the root superimposed with the image of the defect, tends to obscure bone height. Bone loss in furcation areas may be obscured by an overlying root or bony shadow.

- *Less accuracy of bone destruction*—radiographic image will tend to show less severe destruction than in the actual in the case.
- *Soft to hard tissue relationship*—soft to hard tissue relationship are not demonstrated on the radiographs.
- *Technique variation*—technique variation and X-ray beam position can considerably affect the appearance of the periodontal tissues.
- *Burn out*—overexposure can cause burn out.

Radiographic Features of Healthy Periodontium

- *Posterior region*—thin, smooth, evenly corticated margins of the interdental crestal bone in the posterior regions. It is just below the Cementoenamel junction. The interdental crestal bone is continuous with the lamina dura of the adjacent teeth. The junction of two forms a sharp angle (Fig. 24-53).
- *Anterior region*—thin, even, pointed margins to the interdental crestal bone in the anterior region. Cortication at the top of the crest is not always evident, mainly due to a small amount of bone between the anterior teeth. Thin and even width of the mesial and distal periodontal ligament space.

Fig. 24-53: Radiograph of normal periodontium.

Radiological Types of Periodontitis

Early Periodontitis

There are areas of localized erosion of the alveolar bone crest.

In the anterior region, there will be blunting of the alveolar bone. In some cases, it presents chisel edge, due to greater destruction of bone at the sides than at the summit.

In posterior areas there is loss of the sharp angle between the lamina dura and alveolar crest and it appears rounded off, with irregular and diffuse borders.

Moderate Periodontitis

There are two types:

Horizontal bone loss

- In horizontal bone loss, both, buccal and lingual bone plates and intervening inter-dental bone resorbed (**Fig. 24-54**). It does not indicate the current activity of disease.

Fig. 24-54: Horizontal bone loss present between premolar and first molar.

- *Appearance*—radiographic appearance of loss in height of the interdental alveolar bone with the crest still horizontal and perpendicular to the long axis of the adjacent tooth.
- *Types*—it may be localized (**Fig. 24-55**) or generalized, depending on the areas involved. It may be mild, severe and moderate depending on the amount of bone loss.
- *Horizontal bone loss after surgery*—some patients, who have undergone periodontal surgery, may show

Fig. 24-55: Horizontal bone loss present in the anterior region.

moderate bone loss, but condition may be stable and without continuing bone loss and this may be indicated by a relatively dense apex.

Osseous defects

It is a type of bony lesion that may be seen in moderate periodontitis, other than horizontal bone loss. It is difficult to locate on radiographs. There are various types of osseous defects.

- *Inter-proximal crater*—it is the most common type of bony deformity. It is a trough like depression that occurs in the crest of inter-proximal septal bone between two adjacent teeth. It consists of two side walls vestibular and lingual cortical plates. The image of the side walls that is projected more coronally will be reduced in density, in relation to the image of apical side wall which is superimposed over the other side wall. If two walls are exactly superimposed, the inter-proximal crater may appear as an irregular linear area of reduced density between the adjacent teeth. Craters that are radiographically detected are about 1 mm or more in depth. The apical margin of the defect will not be sharply demarcated and will be such that relatively radiolucent image of the crater will gradually blend with the normal bone is apical to it.
- *Proximal intrabony defect*—it is a vertical defect within the bone. It extends apically, from the alveolar crest and is surrounded by three walls of bone, i.e. hemisepta and two marginal walls (lingual and vestibular) roots of the affected tooth is the fourth wall.
- *Hemisepta*—it is the bone of the interdental septum that remains on the roots of uninvolved adjacent tooth after destruction of either distal or mesial portion of the interproximal bone septum (**Fig. 24-56**). It occurs as a result of occlusal trauma which is complicated by inflammation. It is more common on distal surfaces of

Fig. 24-56: Hemisepta present in premolar tooth.

teeth. Loss of attachment is increased in tooth mobility and open contact. It is V shaped and sharply outlined. Crestal lamina often appears at the coronal limit of the side wall. Gutta percha point is used to detect such cases.

- **Inconsistent bony margins**—it is the result of uneven resorption of alveolar cortical plates on the lingual or vestibular surface, with the result in that the crests of bony margins are irregular. It occurs when marginal bone is thin and removed by inflammatory process. It forms quite rapidly and remains constant for long periods. Difficult to identify on radiographs because it is obscured by the image of the root. Irregular margins apparent will relatively be opaque and more or less continuous with the lamina dura of interproximal crest, but apical to it. Radiographically it is not possible to determine the side of the tooth affected.
- **Bony pocket**—osseous defects, sometimes, form in the vestibular or lingual bone over the root and they are called as bony pockets (**Fig. 24-57**). They are surrounded by roots of involved teeth and cortical bone. They are extensions of proximal bony defect. Only detected when there is high degree of contrast between the thinned bone over the root and the surrounding bone.

Fig. 24-57: Bony pocket seen in relation with the mandibular first molar.

Advanced Periodontitis

It is defined as the bone loss which is so extensive that the remaining teeth show excessive mobility, drifting and are in jeopardy of being lost due to inadequate support

Osseous Deformities in Furcation of Multi-Rooted Teeth

- **Furcation involvement**—progressive periodontal disease and its associated bone loss, may invade the bifurcation of multi-rooted teeth. It is found that the level of alveolar crest falls to occupy a position near the apices, so that

the major part of the root is often denuded. Bone resorption extends down the side of multi-rooted teeth, eliminating the marginal cortical bone over the root and it reaches the level of furcation and even beyond it.

- **Site**—the most common area for furcation involvement of maxillary 1st permanent molar is from its mesial side. Early maxillary molar furcation involvement between the mesiobuccal or distobuccal roots and the palatal root, produces a characteristic triangular shaped radiolucency at the edge of the tooth (**Figs 24-58A and B**). The pocket which is situated on the mesial or distal part of a tooth and occupies a small portion of the interdental septum on the lingual or buccal aspect only, may cross the adjacent root and involve the corresponding mesial or distal aspect of the bifurcation, producing only very slight bone changes.
- **Appearance**—mesial and distal furcation involvement is not apparent on radiographs because of presence of one or both cortical plates. If there is sufficient bone loss between lingual and buccal aspect of furcation in

Figs 24-58A and B: Severe bone loss seen in furcation area of molar teeth.

mandibular molar, radiolucent image will be sharply outlined. If it involves only one plate, then the image will be irregular in outline.

Alveolar Dehiscence

It results when the marginal bone chips apically and exposes the length of the root surface. The defect is wide and irregular and extends as far as the apex of affected teeth (**Fig. 24-59**). It occurs on either lingual or vestibular side of the tooth. On radiographs, it will appear as a faint radiopaque line representing its apical extension.

Fig. 24-59: Alveolar dehiscence showing faint line extending at the apex of tooth.

Introduction

TMJ is a unique joint in which translatory as well as rotational movements are possible and where both the ends of bone articulate, in the same plane, with that of other bone. It is also called as ginglymodiarthrodial type of joint, meaning that it has a relatively sliding type of movement between bony surfaces, in addition to hinge movement, common to diarthrodial joint.

Anatomy of TMJ

The TMJ is located between the mandibular fossa (glenoid fossa), the inferior surface of temporal bone and condylar process of the mandible. It is a synovial type of joint and it is distinguished from most of the joints by following points.

- **Fibrocartilage**—articulating surface of the bones is covered by avascular, fibrous connective tissue, which may contain variable number of cartilage cells. Thus called as fibrocartilage.
- **Point of closure**—the two articulating surface complex of bone carry teeth, whose shape and position influence the movement of joint. It is the only joint with rigid end point of closure.
- **Articulation**—it has bilateral articulation with cranium, so both the joints must function together. TMJ is a complex joint as it has an articular disc interposed between the condyle and the temporal bone (**Figs 25-1A and B**).

Joint Proper

Glenoid Fossa

The mandibular condyle articulates at the base of the cranium with the squamous portion of the temporal bone. This is called as the glenoid fossa.

Figs 25-1A and B: Normal positioning of disc in temporomandibular joint—front and lateral view.

- **Surface**—this is a continuous surface consisting of three regions:
 - The posterior slope to the height of convexity of the articular eminence just anterior to the glenoid fossa.
 - The flattened preglenoid plane continuing anteriorly from the height of eminence.
 - Entaglenoid process is continuous with the narrow glenoid plane.

- *Squamous tympanic fissure*—posterior to the glenoid fossa, there is a squamous tympanic fissure, which extends mediolaterally.
- *Post-glenoid process*—the posterior part of the fossa is elevated to form a ridge called the posterior articular ridge. This ridge increases in height laterally to form the thickened cone shaped prominence called the post-glenoid process, immediately anterior to the external acoustic meatus.
- *Entaglenoid process*—the lateral border of the fossa is usually raised to form a narrow crest joining the articular tubercle in front, with the post-glenoid process behind. Medially, the articular fossa narrows and is bounded by a bony wall, the entaglenoid process.
- *Roof*—the roof of the glenoid fossa is always thin and even translucent in many skulls. There is clear evidence that the articular fossa is not a stress bearing functional part of TMJ articulation.
- *Articular eminence*—the articular eminence is strongly convex in an anteroposterior direction and somewhat concave in a transverse direction. The degree of convexity varies, with the radius of the curvature varying from 5 to 15 mm.

Mandibular Condyle

- *Dimension and shape*—the condyle is about 15 to 20 mm long and 8-10 mm thick. Its long axis lies at right angle with the plane of the ramus. The condyle is usually quite convex anteroposteriorly and only slightly convex mediolaterally. The mediolateral convexity is often irregular, with medial and lateral slopes divided by a more or less prominent anteroposterior ridge.
- *Poles*—the articular surface of the mandible is seated on its ovoid condylar process. From the anterior view, it has medial and lateral projections called *poles*.
- *Lateral pole*—the lateral pole of condyle is roughened and often bluntly pointed.
- *Medial pole*—the medial pole is usually rounded and is more prominent than the lateral pole.
- *Lateral view*—in lateral view, the condyle appears tilted forward at the mandibular neck, with its articular surface on its anterosuperior aspect. The articular surface thus faces the posterior slope of the articular eminence, when the jaw is held with teeth in complete occlusion.
- *Articular surface*—the articular surface continues medially down and around the rounded medial pole of the condyle. Medial articular surface faces the entaglenoid process of the temporal bone, when the jaw is held in an occluded position.

Articular Disc

It is composed of dense fibrous connective tissue devoid of any blood vessels or nerve fibers.

- *Intermediate zone*—in the sagittal plane, it can be divided into three regions according to thickness. The central area is the thinnest and is called as *intermediate zone*. Both anterior and posterior to the intermediate zone, the disc becomes considerably thicker. The posterior border is generally slightly thicker than the anterior border.
- *Anterior view*—from the anterior view, the disc is generally thicker medially than laterally. The precise shape of the disc is determined by the morphology of the condyle and mandibular fossa. During movement, the disc is somewhat flexible and can adapt to the functional demands of the articular surface.
- *Retrodiscal tissue and lamina*—the articular disc is attached posteriorly to an area of loose connective tissue that is highly vascularized and innervated it is called as *retrodiscal tissue*. Superiorly, it is bordered by the lamina of connective tissue, which contains many elastic fibers, the superior *retrodiscal lamina*. This gives necessary freedom for anterior movement of the disc. Since this region consists of two areas, it is called as bilaminar zone.
- *Attachment*—the articular disc is attached to the capsular ligament anteriorly, posteriorly as well as medially and laterally. This divides the joint into two distinct cavities; the upper or superior cavity which is bordered by the mandibular fossa and superior surface of the disc and the lower or inferior cavity, which is bordered by the mandibular condyle and inferior surface of the disc.
- *Synovial fluid*—the internal surface of the cavity is surrounded by specialized endothelial cells that form the synovial lining. This lining along with a specialized synovial lining located at the anterior border of the retrodiscal tissue produce the *synovial fluid*, which fills both the joint cavities. Thus, TMJ is referred to as a synovial joint.

Ligamentous Structures

Functional Ligament

- *Collateral ligaments (Fig. 25-2)*—the collateral ligaments attach the medial and lateral borders of the articular disc to the poles of the condyle. It is commonly called as *discal ligament* and are two in number. The medial one attaches the medial edge of the disc to the medial pole of the condyle and the lateral one, attaches to the lateral edge of the disc to the lateral pole of the condyle. These ligaments are responsible for dividing the joint mediolaterally into the superior and inferior joint cavities. Their function is to restrict the movement of the

disc away from the condyle, as it glides anteriorly and posteriorly. The reason for it is that they contain collagenous connective tissue fibers which cannot be stretched. They have a vascular supply and are innervated. The innervations provide information regarding the joint position and movement.

Fig. 25-2: Collateral ligament—A diagrammatic representation.

- **Capsular ligament (Fig. 25-3)**—the entire TMJ is surrounded and encompassed by the capsular ligament. The fibers of the capsular ligament are attached superiorly to the temporal bone, along the border of the articular surface of the mandibular fossa and articular eminence. Inferiorly, the fibers are attached to the neck of the condyle. It acts to resist any medial, lateral or inferior forces that tend to separate or dislocate the articular surface. Another function is to encompass the joint, thus retaining the synovial fluid. It is well innervated and provides proprioceptive feedback regarding the position and the movement of joint.

Fig. 25-3: Capsular ligament—A diagrammatic representation.

- **Temporomandibular ligament (Fig. 25-4)**—it is also called as *lateral ligament* as it is located laterally to the joint. It is composed of two parts, an outer oblique portion and an inner horizontal portion. The outer portion extends from the outer surface of the articular tubercle and zygomatic process, posteroinferiorly to the outer surface of the condylar neck. The inner horizontal portion extends from the outer surface of the articular tubercle and zygomatic process posteriorly and horizontally to the lateral pole of the condyle and posterior part of the articular disc. The oblique portion of the ligament resists excessive dropping of the condyle and therefore acts to limit the extent of mouth opening.

Fig. 25-4: Temporomandibular ligament—A diagrammatic representation.

Accessory Ligaments

- **Sphenomandibular ligament**—it is attached to the spine of the sphenoid bone and extends downwards and laterally to the small bony prominence on the medial surface of the ramus of the mandible, called the *lingula*. It does not have any significant effect on mandibular movement.
- **Stylomandibular ligament**—it arises from the styloid process and extends downward and forward to the angle and posterior border of the ramus of the mandible. It becomes taut when mandible is protruded but is most relaxed when the mandible is opened. Its function is to limit the excessive protrusive movements of mandible.
- **Mandibular malleolar ligament**—actually, the mandibular malleolar ligament consists of fibroelastic tissue with some ligamentous qualities. It originates from the neck and anterior process of malleus and is inserted on the medioposterior and superior part of the capsule, interarticular disc and sphenomandibular ligament.

Synovial Fluid

- **Volume**—the passive volume of upper and lower joint cavity is 1.2 and 0.8 ml respectively. A small amount of a clear, straw colored viscous fluid is found in the articular spaces, which is known as *synovial fluid*.
- **Source**—it is secreted by synovial membrane lining the articular disc, the capsule and also by retrodiscal tissue lining.
- **Properties**—synovial fluid is characterized by well defined physical properties of viscosity, elasticity and plasticity. It contains small population of varying cell type such as monocytes, lymphocytes, free synovial cells and occasionally polymorphonuclear leukocytes. The chemical composition of synovial fluid indicates that it is dialysate of plasma, with some added protein and mucin.
- **Gelation**—when the TMJ movements are reduced or restricted due to some reasons, the synovial fluid becomes viscid; its lubricating qualities are seriously impaired, a condition clinically referred to as *gelation*.
- **Functions of synovial fluid**
 - **Lubricant**—it is a lubricant and reduces the mechanical friction between the condyle and the articular disc and the mandibular fossa and articular disc.
 - **Nutritional fluid**—it is also a nutritional fluid for the vascular tissues covering the condyle and the articular tubercle and also for the disc. It is elaborated by diffusion from the rich capillary network of the synovial membrane, augmented by mucin secreted by the synovial cells.
 - **Liquid environment**—it provides liquid environment for the joint surface.
 - **Cleaning of joint**—synovial fluid is also considered to be responsible for the removal of entraneous material shed into the joint cavity. The intimate cells have been demonstrated to possess marked phagocytic properties.

Joint Innervations

- **Vascular supply**—it comes from the branches of the superficial temporal arteries, deep auricular arteries, anterior tympanic arteries and ascending pharyngeal arteries.
- **Nerve supply**—it is innervated by the branches of auriculotemporal nerve, masseteric nerve and the posterior deep temporal nerve, which are branches of the mandibular portion of the trigeminal nerve.

Functional Movement of TMJ

- **Elevation (jaw closing)**—the mandibular elevators include the coordinated functions of masseter, temporal and

medial pterygoid muscle of both the sides. Temporalis maintains the physiological rest position of the mandible. The posterior fibers of temporalis retract the head of mandible while closing the mouth.

- **Depression**—the depression of mandible includes the activity of the lateral pterygoid and the suprahyoid muscles. The inferior head of the lateral pterygoid is the main muscle used for depressing the mandible. The superior head of the lateral pterygoid pulls the articular disc forward, creating the glenoid joint activity. The suprahyoid group of muscles also acts in mandibular movement; by initiating and assisting opening of the jaw. The lateral pterygoid muscle has a major role, particularly when the mouth is opened wide or against resistance by the digastric, geniohyoid and mylohyoid muscle. The infrahyoid group of muscles participates in the activity by fixing the hyoid group to exert a downward pull on the mandible.
- **Protrusion**—it is performed by the medial and lateral pterygoid muscle of both the sides.
- **Retrusion**—it is performed by the posterior fibers of temporalis and digastric muscle.
- **Lateral excursive movements**—in this type of movement, the medial pterygoid and lateral pterygoid of each side, act alternately. If the mandible is moved to the right side the medial pterygoid of right side and the lateral pterygoid of left side act simultaneously.

Diagnostic Studies

Radiography

It is the most important diagnostic aid in distinguishing among the disorders that may affect the temporomandibular joint. Routine radiographic examination includes conventional radiography like Transcranial, Transorbital and Transpharyngeal view, etc. But main limitation is that it only shows osseous component and hence, the disease is diagnosed much later.

- **Computed tomography**—tomograms are superior to conventional radiography because of their ability to depict a greater portion of the joint. By providing the series of radiograph, tomography can reproduce small changes in the central portion of the TMJ and therefore decreases the false-negative interpretation (**Fig. 25-5**).
- **Arthrography**—with increasing interest in soft tissue derangement of the TMJ arthrography has assumed an important role in the diagnosis of joint disorders. Defect in the position or structure of the joint disc and its attachment can be determined using arthrography. Arthrography is performed by injecting the contrast media into the joint space and then after radiograph is taken.

Fig. 25-5: 3D CT of temporomandibular joint showing condyle and glenoid fossa.

- *Electromyography*—it provides an objective means of providing monitoring the changes in the muscle activity and therefore can be a valuable aid in diagnosing MPDS and in evaluating the effectiveness of the treatment.
- *Arthroscopy*—steroid induced arthrography, chronic inflammatory changes in the synovium, acute inflammatory disease and gross damage to the condyle and disc could be visualized and diagnosed using arthroscopy in their study.

Table 25-1: Weldon Bell classification

Masticatory muscle disorders

- Protective muscle splitting
- Masticatory muscle spasm—MPD
- Masticatory muscle inflammation—myositis

Derangement of TMJ

- Incoordination
- Anterior disc displacement with reduction (clicking)
- Anterior disc displacement without reduction (mechanical restriction, closed lock)

Extrinsic trauma

- Traumatic arthritis
- Dislocation fracture
- Internal disc derangement
- Myositis
- Myospasm
- Tendonitis

Degenerative joint disease

- Non-inflammatory phase—arthrosis
- Inflammatory phase—osteoarthritis

Inflammatory joint disorders

- Rheumatoid arthritis
- Infective arthritis
- Metabolic arthritis

Chronic mandibular hypomobility

- Ankylosis—fibrous and osseous
- Fibrosis of articular capsule
- Contracture of elevator muscles
 - Myostatic contracture
 - Myofibrotic contracture
- Internal disc derangement—closed lock

Growth disorders of the joint

- Developmental disorders
- Acquired disorders
- Neoplastic disorders

Table 25-2: Second classification

Intracapsular

Degenerative joint diseases

- Osteoarthritis

Inflammatory

- Rheumatoid arthritis (and other collagen disorders)
- Psoriatic arthritis

Infection

- Gonorrhea
- Spread from contiguous sites
- Tuberculosis
- Syphilis

Developmental

- Condylar hyperplasia
- Condylar hypoplasia
- Agenesis

Traumatic

- Condylar fracture
- Ankylosis
- Dislocation
- Disc displacement

Metabolic

- Gout

Neoplasia

- Benign
- Malignant

Drug induced

- Steroid

Extracapsular

- Psycho-physiologic (MPD)
- Iatrogenic
- Traumatic
- Those referred from local dental origin
- Infection
- Otologic
- Neoplastic

Classification of TMJ Disorders

It is described in **Tables 25-1 and 25-2**.

Developmental Disorders of the TMJ

Hypoplasia of Condyle

It is the underdevelopment of mandibular condyle which can be congenital or acquired.

Causes

- *Prenatal growth disturbances*
 - *Hereditary*—hereditary anomalies like chromosomal anomalies, achondroplasia, mandibulofacial dysostosis, progeria, Larsen's syndrome and Goldenhar syndrome can lead to hypoplasia of condyle.
 - *Non-hereditary*—non-hereditary disease like Pierre Robin syndrome, radiation to fetus, Mobius syndrome are also causative factors.
- *Postnatal growth disturbances*
 - *Endocrine*—hypothyroidism and hypopituitarism causes decrease in secretion of growth hormone resulting in hypoplasia of condyle.

- **Trauma**—it is the most common cause of hypoplasia. Trauma may occur in infancy or childhood.
- **Nutritional factors**—deficiency of vitamin A and some other nutritional deficiency in the early infancy and childhood can lead to hypoplasia of condyle.
- **Infection**—rheumatoid arthritis can cause inhibition of growth of a component of the joint.
- **Irradiation**—radiation upon the face during the period of growth and extent of the change in the size of the condyle depends to some extent on the amount of radiation that is applied and the age at that time.

Clinical Features

Unilateral

- In this, only one side is involved. Following features can be present in unilateral hypoplasia.
 - **Appearance of face**—on the unaffected side, there is elongation of the body of mandible and flat appearance of the face. Body of mandible is short on affected side.
 - **Shifting on affected side**—mandible shift towards the affected side on opening.
 - **Malocclusion**—malocclusion is present. There may be cross bite on the affected side.
 - **Eruption of teeth**—eruption of teeth may be delayed in case of hypoplasia of the condyle. In some cases, it will cause impacted and unerupted teeth.
 - **Ear**—there may be deficiency of some parts of the adjacent auditory apparatus. The external ear may be small, deformed, partially or completely absent.

Bilateral

- In this, both the condyle are affected. Following features are present in this type.
 - **Mandible**—when there is bilateral arrest of condylar growth, there is usually symmetrical lack of growth of the mandible.
 - **Micrognathia**—due to lack of mandibular growth, micrognathia with the chin retracted to the level of hyoid bone occurs.
 - **Eruption**—there is delayed eruption of teeth on the both side.
 - **Class II malocclusion**—patient is having Class II malocclusion. It occurs as the mandibular ramus does not increase in height sufficiently to open the space between the upper and lower jaws into which the teeth erupt with concomitant growth of alveolar process. Another reason for this is that posterior growth of the ramus is affected, so the length of the body of the mandible is diminished and the last molars are left within the ramus.

Radiological Features

- **Condyle**—condylar process is short and it tends to assume a more posterior position in the glenoid fossa (**Fig. 25-6**). The neck of the condyle is slender.

Fig. 25-6: Hypoplasia of condyle occurs on left side (Courtesy Dr Ashok L).

- **Ramus and body of mandible**—there may be proportionate shortening of the ramus and body on the affected side and the bone tends to be smaller than the opposite side. A shallow sigmoid and antegonial notch is also present.
- **Coronoid process**—coronoid process is relatively large, heavier and posteriorly directed.
- **Teeth**—teeth may be impacted.
- **Ear**—in some cases, there is congenital absence of the auditory canal and middle ear and the tympanic plate is poorly developed, so when the condyle is present, the articular fossa gives an appearance of an increased size.
- **Bilateral involvement**—in cases of bilateral underdevelopment, all the above features plus bilateral antegonial notching is seen.

Diagnosis

- **Clinical diagnosis**—malocclusion, elongation of body of mandible on unaffected side will give clue to the diagnosis.
- **Radiological diagnosis**—size of condyle is easily diagnosed on radiograph.

Management

- **Surgical**—surgical procedures commonly used in unilateral deformities are directed towards contributing bulk and increasing the length by means of bone, cartilage and soft tissue grafts. Most commonly graft is costochondral rib graft.
- **Orthodontic treatment**—it is done to correct malocclusion.

Agenesis of the Condyle

It is rare disorder. It is seen in hemifacial macrostomia, Goldenhar syndrome and Hallermann-Streiff syndrome.

Clinical Features

- *Site*—it can occur unilaterally or bilaterally and is a very rare condition.
- *Symptoms*—there are free movement (eccentric movement), anterior open bite, asymmetry of face, altered occlusion. Mastication may be difficult.
- *Signs*—shift of mandible towards the affected side occurs during opening in unilateral type, but it is absent in bilateral type.
- *Associated anomalies*—it is frequently associated with other anomalies like defective and absent external ear, an underdeveloped mandibular ramus or macrostomia.

Radiological Features

- *Absence of condyle*—absence of condyle is easily detected on radiograph.

Diagnosis

- *Clinical diagnosis*—eccentric movement with asymmetry of face.
- *Radiological features*—absence of condyle can be seen radiologically.

Management

- *Maintenance of dental health*—dental intervention can aid by establishment of an acceptable plane of occlusion, maintaining the oral health and offering palliative treatment for discomfort.
- *Osteoplasty*—if the derangements are severe, osteoplasty is advocated.

Hyperplasia of the Condyle

It is rare disorder which is characterized by excessive growth of condyles.

Causes

- *Developmental*—it may occur due to trauma during the birth.
- *Neoplastic*—some tumors like chondroma, osteochondroma or osteoma of condyle can lead to hyperplasia of condyle.
- *Bone disease*—fibrous dysplasia, Paget's disease which affects the bones, may affect the condyle leading to its overgrowth.
- *Hereditary*—this is also suggested the cause for condylar hyperplasia. Condylar hyperplasia can be seen in hereditary syndrome like Klinefelter syndrome.
- *Endocrine*—endocrine disorders like gigantisms as it affects the whole body, it can also affect the condyle causing its overgrowth.

- *Hypertrophic arthritis*—this is rare condition and it may lead to enlargement of the mandibular condyle.
- *Local circulatory disturbance*—local circulatory disturbance around the condyle may activate bone formation in that area causing its overgrowth.

Clinical Features

- *Age and sex distribution*—it occurs in either sex and there is no predilection for any side. Most common age of occurrence is 15 to 19 years.
- *Unilateral type*—it can affect only one condyle. Following features are present in unilateral type:
 - *Mandibular enlargement*—there is progressive enlargement of the mandible on the affected side.
 - *Facial asymmetry*—enlargement on the affected side, give rise to facial asymmetry on that side.
 - *Shift in midline*—due to facial asymmetry, shifting of the midline of chin to the unaffected side.
 - *Malocclusion*—unilateral type will result in cross bite, open bite, and asymmetric protrusion on the affected side.
- *Bilateral*—in this both the condyle are affected. Following features are present in bilateral type:
 - *Anterior cross bite*—mandible is larger on both side and is placed more forward than the maxilla. This will result in anterior cross bite (mandibular teeth are anterior to the maxillary teeth).
 - *Signs*—obtuse mandibular angle and the sigmoid notch form an arc of a larger circle of mandible.
 - *Relative microdontia*—as there is definite disproportion between normal size of crown of teeth and larger size of jaw bones, teeth appear to be smaller as compared to large size of jaw.

Radiological Features

- *Ramus*—the vertical ramus is increased in vertical depth as well as in its anteroposterior diameter. It will result in prevention of occlusion of the posterior teeth.
- *Body of mandible*—body of the affected side of mandible are larger as compared on unaffected side.
- *Condyle*—the condylar enlargement is sometimes symmetrically distributed throughout the whole process. It may retain its normal shape or it may assume a conical, spherical, pear shaped or an uneven and lobulated shape (**Figs 25-7 and 25-8**). The neck of the condyle may retain its integrity, be enlarged or absorbed into the enlarged head of the condyle.
- *Articular eminence*—the articular eminence is shallower than the opposite normal side, with the distal surface slightly evacuated.
- *Displacement of condyle*—hyperplasia of condyle may result in displacement of condyle from the mandibular fossa.

Fig. 25-7: Large size of condyle seen on the computed tomogram (Courtesy Dr Avinash Kshar and Dr Umarji).

Fig. 25-8: Note large size of condyle on right side (arrow) as compared to on left side (Courtesy Dr Avinash Kshar and Dr Umarji).

- **Mandibular angle**—the angle of the jaw is right angle in some cases and it may be more obtuse than normal in some cases.
- **To assess the degree of bone activity**—it is done with the help of Scintigraphy using ^{99m}Tc .

Diagnosis

- **Clinical diagnosis**—enlargement of mandible with shift in midline will give clue to diagnosis.
- **Radiological diagnosis**—enlargement of condyle can be seen radiologically.

Differential Diagnosis

- **Hemifacial hyperplasia**—it is associated with soft tissue and teeth enlargement.

Management

- **Surgery**—unilateral condylectomy should be performed to improve function and esthetics of the patient.
- **Maxillary osteotomy**—some time, there may be occurrence of compensatory maxillary growth. In these cases, maxillary osteotomy should be performed.
- **Orthodontic therapy**—this is done to treat cross bite of the patient.

Double Condyle or Bifid Condyle

In this, double headed mandibular condyle is seen. Condyle is divided by an anteroposterior groove.

Cause

- **Trauma**—childhood fracture may lead to bifid condyle.
- **Developmental**—persistence of the well vascularized fibrous tissue septa, which is normally present in the condylar cartilage during embryonal and early postnatal life. Possible rupture of some of the blood vessels contained within the septa might impair the ossification of the condyle so as to cause a bifid development of the condylar head.
- **Abnormal muscle attachment**—this will also cause bifid condyle.

Clinical Features

- **Age and sex distribution**—it is noticed at any age and is more common in females than male with a ratio of 3:2.
- **Location**—it is usually unilateral. But bilateral occurrence can also be seen.
- **Symptoms**—limitation of opening of mouth, a small lateral deviation. In some cases, click of pop is heard while patient open the mouth.
- **Signs**—lateral movement of mandible is limited.

Radiological Features

- **Bilobed appearance**—radiographs will show bilobed appearance of the condyle (**Fig. 25-9**).
- **Separate glenoid fossa**—there may be two separate glenoid fossa.

Diagnosis

- **Clinical diagnosis**—not so specific.
- **Radiological diagnosis**—bilobed appearance can be seen.

Fig. 25-9: Bilobed appearance seen on radiograph of bifid condyle.

Management

- **Surgical**—as such no treatment is necessary, but if it is causing some problems surgical approach is carried out.

Coronoid Hyperplasia

It is rare developmental disorder affecting the coronoid process of mandible.

Causes

- **Endocrine**—as most of the cases are seen in puberty in the males, some sort of endocrine influence is suggested as the cause of coronoid hyperplasia.
- **Hereditary**—some cases are reported in sibling as hereditary factors may also play some role in coronoid hyperplasia.
- **Tumors**—tumors like osteoma and osteochondroma can also cause unilateral enlargement of the coronoid.

Clinical Features

- **Age and sex distribution**—it is seen in 2nd decade of life and most commonly encounter in males in the ratio of 5:1.
- **Unilateral coronoid hyperplasia**—in unilateral type, there is restriction of mandibular movement. It occurs due to enlarged coronoid may impinge on the zygomatic surface causing reduction in the mandibular movement. There is also deviation of mandible on the affected side.
- **Bilateral coronoid hyperplasia**—in this, limitation of movements occur which become more severe as the age progress.

Radiological Features

- **Unilateral**—In this case irregular nodular growth of the tip of the coronoid process is seen.
- **Bilateral**—there is symmetrical enlargement of coronoid on both sides.

Diagnosis

- **Clinical diagnosis**—not so specific.
- **Radiological diagnosis**—coronoid growth can be seen radiologically.

Management

- **Coronoidectomy**—it is carried out to remove the elongated process of coronoid.

Degenerative Joint Diseases

Osteoarthritis

It is also called as 'osteoarthrosis' or 'degenerative arthritis'. It is primarily a disorder of movable joints characterized by deterioration and abrasion of the articular cartilage with formation of new bone at the joint surface. There is destruction of the soft tissue component of the joint and subsequent erosion with hypertrophic changes in bone. There is breakdown of the connective tissue covering the condyle, articular eminence and the disc. Recently, there are some evidences suggesting that there are some inflammatory components present in osteoarthritis.

Etiopathogenesis (Fig. 25-10)

- **Overload to joint**—the lesion is brought by an increase in the functional demands of the healthy tissue due to repetitive overload on joint. This will result in breakdown of the joint.

Fig. 25-10: Diagrammatic representation of etiopathogenesis of osteoarthritis of TMJ.

- *Deterioration of functional capacity of joint*—there may be normal load to the joint but functional capacity is reduced as a part of aging. This occurs due to:
 - *Slower replacement of chondroblasts*—as age advances there is slower replacement of chondroblasts and chondrocytes in the joint.
 - *Susceptible fibers*—the cartilage matrix turns over less rapidly resulting in available fibers to work for longer period of time. This will make them susceptible to fatigue.
 - *Poor nutrition to joint*—as matrix contain less water, the marrow blood flow diminished which results in poor nutrition to the joint. This will make joint desiccated and brittle.
- *Remodelling theory*—by another theory, bone growth does not cease completely after puberty and remodelling of the joint progresses under functional demands. Degenerative joint disease may develop when the remodelling rate of bone exceeds that of the cartilaginous repair. The gross evidence of these changes is the formation of marginal osteophytes with development of new bone in the area adjacent to the cartilage.

Causes of Secondary Osteoarthritis

- *Developmental*—Perthes disease, epiphysiolysis.
- *Metabolic*—alkaptonuria, hemochromatosis. Wilson's disease and chondrocalcinosis.
- *Traumatic*—intra-articular fracture, menisectomy, hypermobility, long leg arthropathy.
- *Endocrine*—acromegaly, gout.
- *Others*—hemophilia, aseptic necrosis, sickle cell disease, decompression sickness, tabes dorsalis etc.

Types

- *Primary*—it is generally described as a condition due to wear and tear and is more common with increasing age. It is commonly seen in patients more than 50 years of age.
- *Secondary*—the joint changes occur in response to recognizable local or systemic factors. It is more commonly seen in young persons.

Clinical Features

- *Age and sex*—it occurs in patients older than 40 years of age and 85% of them are older than 70, with a mean age of 53 years. Females are affected 6 times as frequently as males.
- *Joints involved*—it is common in many joints, but it is not frequently found in TMJ.
- *Symptoms*—there is unilateral pain over the joint, which may be sensitive to palpation. Patient also experience

pain on movements or biting, which may limit mandibular function. Pain usually worse in the evening.

- *Signs*—there is deviation of the jaw towards the affected side. Affected joint is swollen and warm to touch. Stiffness of the joint.
- *Crepitations*—there is presence of crepitation of the joint, the sound indicates degeneration within the articulating surfaces of the joint or disc.
- *Jaw movement*—there is limitation of jaw movements, which becomes increasingly apparent with function. Pain is usually located to the immediate preauricular region.
- *Spasm of muscle*—early signs may progress to spasm of the masticatory muscles resulting in stiffness and locking of the jaw. If not treated at this stage, it may lead to irreversible changes in the TMJ.
- *Course*—normal course is between 1 to 3 years. Severe symptoms last for about nine months, but gradually burn out leaving little or no disability.

Radiographic Features

- *Location*—degenerative changes located on the lateral and anterolateral wall of the fossa.
- *Erosion of condyle*—first evidence of erosion of condyle on a radiograph occurs on an average, 6 months after the onset of TMJ pain. This will result in enlargement and shallowing of mandibular fossa (**Fig. 25-11**).

Fig. 25-11: Erosion of condyle seen in osteoarthritis of TMJ (Courtesy Dr Avinash Kshar).

- *Sclerosis*—density is increased as a result of sclerosis. Small crescent-like excavation appears at the superior aspect of the condyle just behind the point of articular contact. This is followed by wooly appearance, with spreading of rarefaction in the bone beneath the articular surface.

Fig. 25-12: Osteophyte formation seen as radiopaque projection on CT scan (Courtesy Dr Avinash Kshar).

- *Saucer shaped lesion*—fully developed lesions are saucer shaped on PA view. This is also called as the destructive phase.
- *Flattened articular eminence*—eminence is flattened or almost removed and anterior half of the superior convex surface of the condyle is converted into a flat plane.
- *Eburnation*—subchondral sclerosis of the condylar head becomes more dense and more radiopaque, is sometimes referred as eburnation.
- *Lipping*—development of lipping (shell like extension) on the anterior borders.
- *Osteophyte formation*—little shreds of the tissue at the margins of the articular cartilage surface may undergo ossification, so that small bony outgrowths or spurs develop which are called as osteophyte (**Fig. 25-12**).
- *Beaking*—extensive osteophytic formation is referred as *beaking*. These usually appear on the anterosuperior aspect of the condyle and lateral aspect of temporal component. In some cases, there is formation of sharp angle, either at the margins or actually on the surface of the articular process.
- *Joint mice*—osteophytes may break off and lie within the joint space, these fragments are called as '*joint mice*'.
- *Loose body*—osteophytes may be separated from its attachment and lie loose in the joint as a type of '*loose body*'.
- *Ely's cyst (subchondral cyst)* (**Figs 25-13 and 25-14**)—minute areas of degeneration filled with fibrous tissue are seen just below the bony surface of the condyle. The small radiolucent areas are usually less sharply defined and may have slightly irregular borders. Some are surrounded by an area of increased density, which may

Fig. 25-13: Ely's cyst presented as radiolucent area in the condyle.

Fig. 25-14: Ely's cyst seen on CT scan in condylar region (Courtesy Dr Avinash Kshar).

be thin and well defined or relatively wide and not so sharply defined. These areas are regarded as cystic and are given the name '*Ely's cyst*'.

- *Joint space*—narrowing of the joint space and bony ankylosis may be seen.
- *Severe cases*—in severe cases, glenoid fossa may appear grossly enlarged because of the erosion of the posterior slope of articular eminence. The condyle may be markedly diminished in size and altered in shape due to erosion and destruction of the condylar head.

Diagnosis

- *Clinical diagnosis*—swollen joint in elderly patient with limitation of jaw movement may give clue to the diagnosis.
- *Radiological diagnosis*—Ely's cyst, osteophytes formation, joint mice, sclerosis, condylar erosion are typical of osteoarthritis
- *Laboratory diagnosis*—biopsy shows cells clumping together and become unevenly distributed throughout the fibrous matrix. It will also show loss of articular surface.

Management

- *Elimination of the cause*—it includes occlusal adjustment or replacement of the missing teeth and ill fitting prosthesis, grinding, treatment of caries and periodontal disease.
- *Relieving the pressure on joint*—occlusal adjustment and occlusal splints may reduce pressure on joint and relieve the symptoms.
- *Analgesic and anti-inflammatory drugs*—for the relief of pain, nonsteroidal anti-inflammatory drugs and analgesics should be given.
- *Physiotherapy*—heat therapy, diathermy and ultrasonic.
- *Myotherapy*—muscle exercises, injection of local anesthetic in TMJ.
- *Arthroscopic lavage*—arthroscopic lavage may give relief in some patients.
- *Doxycycline*—nowadays, low dose doxycycline (collagenase inhibitor, anti matrix metalloproteinase) is giving relief in many patients.
- *Other therapy*—glucosamine, chondroitin sulfate have also shown some success in osteoarthritis of TMJ.

Inflammatory Disorders of the Joint

Rheumatoid Arthritis

It is a debilitating systemic disease of unknown origin, characterized by progressive involvement of the joint, particularly bilateral involvement of large joints. Bony components of the TMJ are affected secondary to the granulomatous involvement of the synovial membrane that subsequently spreads to the articular surface of the condyle. It is non-suppurative inflammatory destruction of joint.

Etiopathogenesis

- *Phase one*—it result from some systemic infection, which evokes an inflammatory response within the joint.
- *Phase two*—as an autoimmune reaction to the antigen generated by the initial inflammation itself or it may be associated with derangement of the immune response to the exogenous antigen.
- *Active phase*—in the *active phase*, TMJ may get involved bilaterally. Bony components of the TMJ are affected secondary to the granulomatous involvement of its synovial membrane that subsequently spreads to the articular surface of the condyle. The joint space enlarges with synovial effusion which attacks the fibrocartilage and ultimately produces erosion of the underlying bone. This causes pain, stiffness and limitation of movement.
- *Chronic phase*—*chronic phase* may follow after active phase. Here, there is proliferation of the synovial membrane due to inflammation this is called as *pannus formation*. This pannus then encroaches the joint space and causes destruction of the articular cartilage. In this

lipping of the condyle and marginal proliferation is seen, this result in narrowing of joint space. Here, predominant clinical findings are crepitus, pain on biting and tenderness. The granulomatous tissue replaces the articular surface and small adhesions develop between the articular surface and disc.

- *Healing phase*—the process then enters the *healing* phase, where the symptoms subside and remodelling of the articular surface occurs.
- *Psychosomatic*—emotional trauma, anxiety and environmental strain can lead to the onset of rheumatoid arthritis.
- *Immunological*—the presence of rheumatoid factor in the serum and synovial fluid of affected patients suggest immunological etiology. Plasma cells and lymphocytes are also present on histological examination.

Clinical Features

General

- *Age and sex distribution*—it more commonly occurs in temperate climate and has its highest incidence in women from 20 to 50 years of age.
- *Sites*—in typical cases, small joints of fingers and toes are the first to be affected. Swelling of the proximal but not the distal, interphalangeal joints give the finger as like spindle appearance and swelling of the metatarsophalangeal joints results in broadening of feet.
- *Symptoms*—symptoms include bilateral stiffness, crepitus, tenderness and swelling over the joint. Fever, malaise, fatigue, weight loss, pain and stiffness in the limb are also evident.
- *Polyarthritis*—polyarthritis develops subsequently, large and weight bearing joints are frequently affected.
- *Subcutaneous or rheumatoid nodules*—there is formation of subcutaneous nodules on the pressure points, sites of friction and various vascular lesions, both necrotizing and obliterative types. Severe deformities of extremity can occur as a result of joint collapse, tendon rupture and muscle involvement.
- *Signs*—the joint may become red, swollen and warm to touch. Muscle atrophy around the joint is common.
- *Hands*—in hands, it may produce an ulnar drift. Bursitis can also occur.

TMJ involvement

- *Acute case*—in acute cases, there is bilateral stiffness, deep seated pain, tenderness on palpation and swelling over the joint. There is limitation in opening of mouth.
- *Referred pain*—pain on biting is referred to the temporal region, ear and angle of mandible.
- *Chronic cases*—in chronic cases, crepitus is the most frequent finding. Functional disturbances like deviation on opening and inability to perform lateral excursions are common.

- *Anterior open bite*—anterior open bite is present due to bilateral destruction and anteroposterior positioning of the condyle.
- *Ankylosis*—fibrous ankylosis of the joint which may be partial or complex occurs in long term.
- *Complication*—subluxation, secondary arthritis, muscular atrophy, and bird-like face can occur.

Radiological Features

- *Joint space*—the pannus may destroy the disc and due to this, the joint space may reduce slightly or substantially, depending on the severity of the condition and the length of time.
- *Condyle*—there is flattening of the head of the condyle. Erosion of the condyle can be seen (Fig. 25-15). In condyle, hollowing out appearance of the cartilage is seen.
- *Articular eminence*—bone destruction which occurs in articular eminence may be slight or confined to the posterior surface or to the inferior convexity. Most of the eminence may be destroyed in severe long continued cases.

Fig. 25-15: Erosion of condyle seen in rheumatoid arthritis (Courtesy Dr Avinash Kshar).

- *Irregular outline of condyle*—as the disease continues, the condylar outline becomes increasingly irregular and ragged. In most severe cases, condyle may be completely resorbed, resulting in loss of vertical support and anterior open bite.
- *Sharpened pencil or mouth piece of flute appearance*—in advanced stages, erosion of anterior and posterior condylar surface at the attachment of the synovial lining occurs, which may resemble a 'sharpened pencil' or 'mouth piece of flute' (Fig. 25-16).

Fig. 25-16: Sharpened pencil appearance seen in rheumatoid arthritis of TMJ.

- *Other features*—subchondral sclerosis and flattening of articular surface may occur with subchondral cyst and osteophytic formation.
- *Radiological staging of rheumatoid arthritis*
 - *Stage I*—periarticular osteoporosis
 - *Stage II*—loss of articular cartilage
 - *Stage III*—erosion (Fig. 25-17)
 - *Stage IV*—subluxation and ankylosis.

Fig. 25-17: CT scan of erosion of condyle (Courtesy Dr Avinash Kshar)

Diagnosis

- *Clinical diagnosis*—subcutaneous nodule, bilateral involvement and pain on biting. Many joints are involved at the same time.
- *Radiological diagnosis*—sharpened pencil appearance, with flattening of articular eminence.
- *Laboratory diagnosis*—biopsy shows proliferation of synovial lining cells with intense infiltration of lymphocytes, plasma cells and polymorphs. Rice bodies are seen histopathologically. Rose Waller test is positive in 70% of the patients with rheumatoid arthritis. There is elevation of RF factor. Antinuclear antibodies are

detected by indirect immunofluorescence. Analysis of synovial fluid is essential for the immediate diagnosis of joint infection, inflammation and degenerative disease.

Management

- *Supportive treatment*—adequate rest to the joint, soft diet is advocated.
- *Intra-articular corticosteroid injections*—local injection of long acting steroids such as methyl prednisone acetate (20-80 mg for large joint and 4-10 mg for small joint) or triamcinolone hexa-acetomide (10-40 mg for large joint and 2-6 mg for small joint) are given.
- *Non-steroidal anti-inflammatory drugs*—these drugs are inhibitory to prostaglandins. These are used for symptomatic relief. Salicylates (for pain) and anti-inflammatory agents like phenylbutazone, indomethacin, ibuprofen, diclofenac and piroxicam can be used.
- *Immunomodulator*—azathioprine is found to be effective in both, high and low doses.
- *Slow acting anti-rheumatic drugs*—these are the antimalarials like hydroxyl chloroquine sulphate, sulphasalazine (500 mg/day) and methotrexate (D-Penicillamine and parenteral gold).
- *Local treatment*—it is done with heat, diathermy, jaw exercise or a mouth stretcher. Muscle strengthening exercise and hydrotherapy.
- *Medical synovectomy*—synovial obliteration is achieved with osmic acid or variety of radiocolloids, if pain is present even after injection of steroids. Erbium acetate is used for small joints, while yttrium silicate is used for large joints.
- *Surgical synovectomy*—it accounts for removal of synovial membrane which is responsible for enzymatic destruction of cartilage.

Juvenile Rheumatoid Arthritis

It is also called as 'Still's disease' and 'Juvenile polyarthritis'. It is defined as a chronic synovitis with or without extra-articular manifestations, but it is accompanied by more systemic features than for adults.

It occurs in children and has its peak between 1 to 3 years. Initial bilateral polyarthritis of both small and large joints including the cervical spine occurs. There is splenomegaly, lymphadenopathy, leukocytosis, pyrexia and rash.

Patient complaint of neck pain, limited range of movement and restricted opening of the mouth. One or both TMJ are involved. It may cause interference with normal condylar growth, leading to micrognathia. This is seen in at least 20% of cases. Persistence leads to deterioration of jaw movement.

Psoriatic Arthritis

It is a chronic disease of unknown etiology characterized by skin lesions and sometimes joint involvement.

Etiopathogenesis

- *Hereditary*—the exact cause is unknown. In some cases, hereditary is the factor, transmitted as a simple dominant trait.
- *Precipitating factors*—in some cases, the precipitating factors include infection by various microorganisms, metabolic disturbances, endocrine dysfunction, neurogenic factors and trauma.
- *HLA factors*—there is evidence that disease is associated with human major histocompatibility (HLA) antigen complex, implying that either the HLA antigen itself or a linked gene is directly involved in the disease process.

Clinical Features

General

- *Location*—skin lesions are found on the trunk, arms, face and scalp.
- *Appearance*—skin lesions exhibit broad irregular papules or plaques, which are dull red to brownish in color and are usually covered with a layer of fine silvery scales.
- *Auspitz's sign*—when scraped, they leave behind small bleeding points: this is called as Auspitz's sign.
- *Exacerbation*—exacerbation occurs after exposure to ultra-violet light.

TMJ involvement

- *Symptoms*—preauricular pain, which is usually unilateral. There is difficulty in opening the mouth.
- *Signs*—TMJ is tender. Crepitus, deviation towards the affected side and in small proportion of cases, deformities are seen.

Radiological Features

- *Articular surface*—generalized appearance of irregularity of condylar articular surface.
- *Osteoporosis*—generalized osteoporosis can occur.
- *Joint spaces*—proliferative changes with diminution of joint space.

Diagnosis

- *Clinical diagnosis*—positive Auspitz's sign with tender TMJ will give clue to the diagnosis.
- *Radiological diagnosis*—generalized irregularity of the bone is present.

Management

- *Drugs*—Systemic drugs like salicylates should be given.

- **Appliance**—screw wedge appliance should be made and is given to the patient.
- **Steroids**—for skin lesion local application steroids.
- **Others**—shortwave diathermy, massage exercise, screw wedge appliance.

Infective Arthritis

It is also called as 'septic arthritis'. It may be acute or chronic.

Etiology

- **Microorganisms**—it is caused by direct spread of organisms like staphylococci, streptococci, pneumococci and gonococci, from an infected mastoid process, tympanic cavity or via blood.
- **Trauma**—it may also be caused by trauma directly to the joint or infection from a maxillary molar and parotid gland.
- **Osteomyelitis and middle ear infection**—it is acute in nature. It can be caused by osteomyelitis and suppurative middle ear infection.
- **Brucellosis**—brucellosis can also cause infective arthritis usually of chronic type but acute infection can occur.

Pathogenesis

- **Dilatation of blood vessels of synovial membrane**—early dilatation of blood vessels of the synovial membrane with serous exudate is accompanied by the usual stages of inflammation. This is followed by suppuration, with formation of pus and ulceration of the synovial membrane.
- **Erosion of articular disc**—the articular disc is eroded and partly destroyed. The cartilage of the head of the condyle and the fossa are similarly affected.

Clinical Features

- **Age and sex distribution**—it usually occurs in young children with no sex predilection.
- **Location**—it is always unilateral. In some cases of chronic variety bilateral involvement can occur.
- **Symptoms**—there is severe pain on jaw movement, with an inability to place the teeth in occlusion, due to presence of infection in the joint.
- **Signs**—redness and swelling over the joint. In some cases, swelling may be fluctuant and extend beyond the region of the joint.
- **Lymph nodes**—tender cervical lymph nodes on the side of infection. This helps to distinguish septic arthritis from other TMJ disorders.
- **Chronic cases**—it may follow an acute infection, but usually it is chronic. In these cases ankylosis of the joint or facial asymmetry (if the growth centers are involved), may occur.

Radiographic Features

Acute

- **Location**—erosion usually seen on anterior and superior aspect of the condyle.
- **Joint space**—in early stages, width of joint space may be increased by inflammatory distension in early infective period. This will cause hazy appearance in radiographs.
- **Articular cortex**—articular cortex of the condyle may become slightly radiolucent. Discontinuities and subtle irregularities of anterior cortical surface may be seen (**Fig. 25-18**).
- **Osteoporosis**—there is considerable osteoporosis of adjacent parts of the condyle and it may extend to whole of the ascending ramus.
- **Sequestrum**—in some cases, there is formation of sequestrum, which if persistent may lead to some added bone destruction.

Chronic

- **Condensing osteitis**—in chronic cases, there may be peripheral condensing osteitis and approximation of the joint surface, as the articular cartilage is eroded.
- **Bone**—there may be frank bone destruction.
- **Condyle**—a small cup shaped excavation on the anterior face of the condyle, having a smooth or irregular base is seen. In rare cases, whole of the condyle may be lost with varying amount of eminence.

Fig. 25-18: Infective arthritis showing destruction of condylar surface on right side (Dr Kshar).

Diagnosis

- **Clinical diagnosis**—severe pain in the joint, with sign of inflammation over the joint will give clue to the diagnosis.

- *Radiological diagnosis*—destructive change in the condyle will give clue to the diagnosis.

Management

- *Rest to joint*—adequate rest to the joint should be given and patient is asked to do limited movements of joint.
- *Liquid diet*—patient should be kept on liquid diet.
- *Antibiotics and analgesics*—appropriate antibiotics and analgesics should be given to patient.
- *Surgical*—if there is suppuration, incision and drainage should be carried out.

Ankylosing Spondylitis

It is also called as 'Marie-Strumpell disease' and 'rheumatoid spondylitis'. It is a chronic inflammatory connective tissue disease that affects the axial skeleton and central joints including the TMJ.

Clinical Features

- *Age and sex distribution*—it is more common seen in young adults and is more common in men than in women.
- *Site*—it primarily involve spine joint. This will result in forward and stopped posture.
- *Signs*—joint stiffness results from immobility (during sleep) and is typically relieved by heat and exercise.

Radiographic Features

- *Flattening*—there is flattening of the articular surface of the TMJ (Fig. 25-19).
- *Osteophytes*—osteophytic formation is common.
- *Erosion*—in some cases, erosion of condylar head is seen.

Fig. 25-19: Coronal section showing flattening of articular surface (Courtesy Dr Avinash Kshar and Dr Umarji).

Diagnosis

- *Clinical diagnosis*—joint stiffness associated with forward and stooped posture of the spine joint.
- *Radiological diagnosis*—flattening of joint surface.

Management

- *Analgesics*—NSAID should be given to the patient to relieve pain and inflammation.

Traumatic Disorders of TMJ

Condylar Fracture

Condyle is displaced medially, inferiorly and anteriorly due to pull from lateral pterygoid muscle. A blow on the point of chin is the usual cause for bilateral fracture of the condyle.

Classification

Intracapsular Fracture

- *Articular surface fracture*—fractures involving articular surface.
- *High condylar fracture*—fractures above or through the anatomical neck, which may be termed as high condylar fracture.
- *Injury to capsule, meniscus and ligament*—fractures associated with injury to the capsule, ligament and meniscus.

Extracapsular Fracture

- *High condylar fracture*—the fracture runs from the lowest point of the curvature of the sigmoid notch, obliquely downwards and backwards below the surgical neck of the condyle, to the posterior aspect of the upper part of the ramus.
- *Low or subcondylar fracture*—the fracture is influenced in its site and its direction by the insertion of part of masseter muscle and TMJ ligament, the fracture taking the line of least resistance. Such a fracture may be termed as low or subcondylar fracture.
- *Combined fracture*—very nearly the condylar head may be split in the anteroposterior or sagittal plane; the split extending through the neck and producing a combined intra- and extracapsular fracture.

Etiology

- *Indirect violence/fight*—the ultimate position of the fractured fragment will depend on direction and degree of violence, precise point of application, presence or absence of teeth or denture and the extent of occlusion which exists at the moment of impact.

- *Parade ground fracture*—if the blow is sustained centrally on the chin then there is a possibility of bilateral fracture of the condyle. It will protect the vital organs in the middle cranial fossa as the thin neck of the condyle will fracture first. This commonly occurs when a soldier faints on a parade ground and hence named as ‘parade ground fracture.’
- *If the teeth are in occlusion*—there is no displacement of the condyle. If the teeth are not in occlusion then displacement of the condyle is definite.
- *Lateral force*—if the force of violence is received laterally, then the fracture occurs at opposite condyle.

Clinical Classification

- *No displacement*—crack/fracture is present without tearing of periosteum or of ligament and without significant alteration in the normal relationship of the condylar head to glenoid fossa or neck of the condyle to the ramus.
- *Deviation*—angulations exist between the condylar neck and ramus.
- *Displacement*—overlapping occurs between the condylar processes and the surgical fragment lies lateral to ramus.
- *Comminuted fracture*—may occasionally be encountered. They are usually associated with a fracture of the zygomatic arch and coronoid process, due to severe road accidents and gun shot wounds.
- *Greenstick fracture*—it is seen in cases of children. If the blow is not severe, this type of fracture occurs with medial and anterior angulations, which tend to correct itself spontaneously with the natural growth.
- *Dislocation*—fractured dislocation of the condylar head occurs due to pull of the muscle.

Importance of Muscle Pull

- *Detachment of disc*—the TMJ capsule is strengthened on the lateral aspect by the temporomandibular ligament, whereas medially, it is comparatively weak. Therefore when a fracture with dislocation occurs (particularly if the line of force is parallel to the slope of the articular eminence and condylar head is positioned anterior to the eminence), due to the pull of external pterygoid, detachment of disc may occur.
- *Dislocation of condyle in upwards direction*—in a closed mouth, muscle pull will dislocate the condyle upwards and posteriorly on the fractured site. Due to fracture, the force of external pterygoid muscle will be ineffective whereas masseter and internal pterygoid muscle will exert combined upward lift which results in backward movement of the fractured end of the ramus on the uninjured disc.

- *Rotation of condyle on unaffected side*—on the unfractured side, there will be rotation of condyle about a vertical axis. The net result is deviation of the mandible to the injured side. During opening, the external pterygoid of the uninjured side will contract but external pterygoid of the injured side will be ineffective as a result there will be more deviation of the mandible to the injured side.

Clinical Features

General

- *Incidence*—condylar fracture accounts for 18% of mandibular jaw fractures.
- *Location*—unilateral fracture of the condyle is more common as compared with bilateral but both occur with or without injury. Fracture is more often associated with dislocation if it is bilateral.
- *Associated fracture*—most of the fractures of condyle are associated with fracture of the opposite side of the mandibular body.
- *Complication*—complication like arthrosis, arthritis, ankylosis and open bite deformity will occur.

Unilateral fractures (Fig. 25-20)

- *Symptoms*—pain on the affected side; it is increased when movement is attempted. Patient complains that his teeth do not occlude in the normal fashion. Patient is also not able to bring the jaw forward.

Fig. 25-20: Transorbital view of the condylar fracture showing medial displacement.

- *Paresthesia of lower lip*—paresthesia of lower lip can occur in some cases. It occurs as hemorrhage from the condylar region, tracks across the base of the skull and exerts pressure on the mandibular division of the trigeminal nerves as it emerges from the foramen ovale.
- *Signs*—small localized swelling over the injured TMJ. There is tenderness over the condylar area of the affected TMJ. There is also occasional crepitus and deviation of the mandible to the affected side.
- *Ear*—there is bleeding from the ear on the affected side which results from laceration of the anterior wall of the external auditory meatus, caused by violent movement of condylar head against the skin in this region.
- *Ecchymosis*—hematoma surrounding the fractured condyle may track downwards and backwards below the external auditory canal. It gives rise to ecchymosis below the external auditory meatus.
- *Limitation of jaw movement*—there is painful limitation of lateral excursion towards the normal side.
- *Gagging*—there is gagging of the ipsilateral molar teeth.

Bilateral Fractures (Fig. 25-21)

- *Gagging on molar teeth*—all the above signs plus variable degree of gagging of the occlusion on the molar teeth.
- *Restricted mandibular movement*—overall mandibular movements are more restricted, than in unilateral fracture.
- *Forward displacement of mandible*—mandible is displaced forwards in case of bilateral fracture.

Fig. 25-21: Bilateral condylar fracture seen on OPG of the patient.

Fracture Dislocation

- *Absence of condyle*—all the above findings plus a definite absence of condyle in the glenoid fossa (Fig. 25-22).
- *Unilateral dislocation*—if the condylar head is dislocated medially and all edema has subsided due to passage of time, it may be possible to observe a characteristic 'hollow' over the region of the condylar head.
- *Bilateral dislocation*—if there is a bilateral dislocation, then there is an anterior open bite present.
- *Central dislocation*—it is a rare type of injury which is usually severe and forces the condyle into the cranial cavity through the floor of the articular fossa. It is termed as central dislocation of the TMJ.

Fig. 25-22: Fracture dislocation showing absence of condyle in the glenoid fossa (Courtesy Dr Datarkar).

Radiographic Features

- *View taken*—displaced condylar fracture is well demonstrated on AP and lateral projection. Non-displaced fracture is well seen on AP view (Fig. 25-23).
- *Increased width of fracture condyle*—when fracture occurs, contraction of the lateral pterygoid muscle rotates the transverse axis of the condylar head, so that the medial end moves anteriorly, thus increasing the apparent width of the fractured condyle.
- *Complete fracture dislocation*—in complete fracture dislocation, the condylar head may be inclined medially at an approximate 45° angle to the vertical axis of the ramus.
- *Anterior displacement of the condyle*—if the condylar head has been displaced anteriorly and turned at 90° angle to the vertical axis of the ramus as viewed from the lateral aspect, then only the articular surface of the condylar head will be seen; this will appear as a narrow radiopaque bar situated in the infratemporal fossa.
- *Condyle split*—the condyle may split with little or no displacement of the fragments, or some portion may be separated from head of the bone. Rarely, the whole of the articular portion is crushed and flattened.
- *CT scan*—in difficult cases, CT scan has been demonstrated to show changes in the relationship of the condyle to the mandibular fossa more precisely than the conventional radiographic examination (Fig. 25-24). It is also claimed that it can demonstrate fine bony alterations at the fractured site.
- *Fracture line*—the fracture line is often transverse but usually oblique, starting in the base of the mandibular

notch and passing slightly or even markedly downwards. In absence of any displacement, it is difficult to visualize such fractures. In the lateral projection, there is often no evidence of any fracture line; but when the posterior margin of the ramus is followed, a sudden step is seen. In some cases there is displacement of the adjacent margins of the fragments, so that the inferior borders of the condylar fragment are superimposed over the adjacent ramus.

- *Articular surface*—the articular surface of the condyle is usually rotated inwards with fracture dislocation.

Fig. 25-23: Subcondylar fracture seen on left side—AP view.

Fig. 25-24: 3D CT scan of patient showing fracture of condyle.

Management

- A *simple crack fracture* without displacement will not require fixation. Patient should be kept under observation and heavy masticatory forces are to be avoided.
- A *fracture with slight displacement* reduction and immobilization of the mandible for a period of 4 weeks.
- *Unilateral fractures with dislocation*—mandible should be immobilized in normal occlusion for ten days then the fixation is released and movement is encouraged. Patients are kept under observation.
- *Bilateral fractures with dislocation*—arch bar is fitted and reduction is achieved by traction in the incisor area. The mandible is immobilized in normal occlusion for 4 weeks.
- *Gunning splints*—for *edentulous patients* gunning splints should be used.
- *Early treatment*—to avoid fibrous ankylosis early movement of TMJ are to be achieved.
- *Other treatment* includes relief of acute symptoms, restoration to proper anatomic relation, intermaxillary fixation for restoration of occlusion and early mobilization to minimize scarring.

Ankylosis

It is also called as '*stiff joint*'. Ankylosis, a Greek word means fusion of body part. It is an abnormal immobility and consolidation of the joint.

Types

- *True (intra-articular)*—it is any condition that produces fibrous or bony adhesion between the articular surfaces of the TMJ.
- *False (extra-articular)*—it is the one which results from pathologic conditions outside the joint, that result in limited mandibular mobility.
- *Bony (true)*—if bone is present between the articulating surfaces and prevents movements, it is called as bony ankylosis.
- *Fibrous (false)*—if the medium which prevent, the movement is fibrous, it is called as fibrous ankylosis.
- *Partial*—if there is incomplete union between the articulating surfaces, it is called as partial ankylosis.
- *Complete*—if there is complete union between the articulating surfaces, it is called as complete ankylosis.

Etiology

False

- *Myogenic*—the most common problem associated with muscle origin is fibrosis, which may result from chronic infection of the elevator muscles of mastication. Myositis ossificans can also produce limitation of opening.

- *Neurogenic*—they include epilepsy, brain tumor, bulbar paralysis and cerebrovascular accidents.
- *Psychogenic*—here, the affected persons exhibit no pain, but patient cannot get the jaws separated also called as hysterical trismus and is apparently produced due to fright.
- *Bone impingement*—the most common is coronoid impingement. Malformation of coronoid such as exostosis or elongation can cause the mandible to impinge on the posterior aspect of the zygoma, when opening is attempted.
- *Trauma*—the formation of fibrous adhesions or cicatricial bands of scar tissues usually occurs after a traumatic accident or burns.
- *Neoplastic disease* like osteochondroma.

True

- *Congenital*—abnormal intrauterine development, birth injuries and congenital syphilis.
- *Trauma*—trauma to the chin forcing the condyle against the glenoid fossa, particularly with bleeding in the joint. Malunion of condylar fractures. Injuries are associated with fracture of the malar-zygomatic compound. In the case of injury to the joint, there is hemorrhage within and outside the joint capsule. Injury occurs during the period of active bone formation. There is immobility of the jaw due to pain or any treatment and ankylosis take place.
- *Inflammatory*
 - Primary inflammation of the joint.
 - Inflammation of the joint secondary to a local inflammatory process (otitis media, osteomyelitis, etc).
 - Inflammation of the joint secondary to a bloodstream infection (septicemia, scarlet fever, gonorrhea).
 - Rheumatoid arthritis is the commonest cause of bilateral ankylosis. Gonococcal arthritis can also cause ankylosis of TMJ.
 - Inflammation secondary to radiation therapy.
- *Others*—loss of tissue with scarring and metastatic malignancy.

Clinical Features

General

- *Age*—it is seen primarily in a young age or between 1 to 10 years.
- *Symptoms*—pain and trismus which is directly related to the duration of ankylosis. Patient also complaint of reduced mouth opening (**Fig. 25-25**).
- *Oral problems*—depending upon the duration, there may be poor oral hygiene, carious teeth and periodontal problems malocclusion (**Fig. 25-26**).

Unilateral

- *Incidence*—unilateral ankylosis is more common than bilateral ankylosis.

Fig. 25-25: Reduced mouth opening seen in patient with ankylosis of temporomandibular joint.

Fig. 25-26: Malocclusion seen in ankylosis patient.

- *Symptoms*—mouth opening is impossible, but the patient may be able to produce several millimeter of interincisal opening.
- *Appearance*—asymmetry of the face with fullness on the affected side (**Fig. 25-27**) and relative flattening on the unaffected side.
- *Deviation of face*—in unilateral ankylosis, patient's face is deviated towards the affected side.
- *Shifting of midline*—the chin is retracted on the affected side and slightly bypasses the midline (**Fig. 25-28**). Slight gliding movement towards the affected side.
- *Cross bite*—cross bite is present due to deviation of mandible and shifting of midline.

Bilateral

- *Bird face appearance*—face is symmetrical with micrognathia. There is bird face appearance (**Fig. 25-29**).

Fig. 25-27: Fullness of face seen on affected side (left) due to ankylosis of TMJ.

Fig. 25-28: Shifting of midline on affected side seen in ankylosis patient.

Fig. 25-29: Bilateral ankylosis showing bird face appearance (Courtesy Dr Lambade).

- *Symptoms*—no gliding movement. With bilateral ankylosis, neither protrusive nor lateral movements are possible.
- *An attempt at forced opening*—in bony ankylosis, there is no pain but in case of fibrous ankylosis, there is pain.

- *Muscles of mastication*—due to long standing ankylosis, atrophy or fibrosis of muscles of mastication may result.
- *Congenital ankylosis*—in case of congenital ankylosis, there is difficulty in introducing the nipple into the mouth of newborn infants.
- *Signs*—class II malocclusion (Fig. 25-30), protrusive incisors and anterior open bite. It is due to the patient's attempt at forcing food through the anterior teeth for a period of years. Patient also suffer from micrognathia (Fig. 25-31).

Fig. 25-30: Protrusive incisor seen in bilateral ankylosis.

Fig. 25-31: Micrognathia seen in patient with bilateral ankylosis.

Radiographic Features

Fibrous ankylosis

- *Appearance*—in some cases, there is transverse or oblique dark line, irregular in outline, crossing the mass of dense bone (Fig. 25-32). When a dark line is present, the possibility of fibrous ankylosis is more.

- *Ramus and body of mandible*—the ramus is vertical and the angle is reduced in size. The body of the jaw is short
- *Condyle*—the condyle may retain its normal shape, but it can be replaced by shapeless mass of bone, which finds attachment to the base of skull above and to the base of neck of condyle below.

Fig. 25-32: Fibrous ankylosis seen in patient showing dark line crossing the bone.

Bony ankylosis

- *Joint space*—joint space is completely or partially obliterated with dense sclerotic bone (**Fig. 25-33**). Sometimes, large mass of new bone may be seen, radiographically obscuring the condyle and joint space.

Fig. 25-33: Complete obliteration of joint spaces. seen in bilateral bony ankylosis.

- *Antegonial notch*—prominent antegonial notch on the affected side of mandible (**Fig. 25-34**), along with inferior arching of the mandibular body (secondary to isotonic contraction of the depressor muscles).
- *Condyle*—bone may form around the neck of the condyle and becomes continuous with the base of the skull. Considerable destruction of bone may precede bony ankylosis. The greater part of the condyle may have been destroyed so that the sigmoid or mandibular notch is approximated to the base of the skull. The neck of the condyle, if not completely hidden by the mass of new bone, appears to be shortened; so that the mandibular notch is nearer the zygomatic process than normal. No translation of condyle head during opening.

Fig. 25-34: Prominent antegonial notch seen on right side of patient in unilateral ankylosis

- *Dark linear shadow*—in some cases, there is horizontal, slightly irregular, dark linear shadow in the middle of the new bone, which represents the cartilage and meniscus.
- *Coronoid process*—there may be deepening of the notch which has escaped involvement in the new bone formation and the appearance may be accentuated by the elongation of the coronoid process, which at the same time is narrow and slender.
- *Computed tomography*—this is nowadays valuable aid in determining the extent of ankylosis (**Figs 25-35A and B**).

Figs 25-35A and B: 3D CT of ankylosis of temporomandibular joint.

Diagnosis

- *Clinical diagnosis*—in bilateral case, bird face appearance or anterior open bite is present. In unilateral cases, deviation of mandible, shifting of midline is present.

- *Radiological diagnosis*—absence of joint space with prominent antegonial notch will diagnose this condition.
- *Laboratory diagnosis*—atrophic or destructive changes in the cartilaginous component of the joint with loss of meniscus are a constant finding.

Management

- *Brisement force*—forceful opening of the jaws under general anesthesia.
- *Condylectomy*—condyle is excised.
- *Gap arthroplasty*—it is performed in the mandibular neck. Two parallel lines are cut, beginning in depth of the sigmoid notch and carried downwards at an angle of 45 degree at the posterior border of the ascending ramus.

Dislocation

It results when condyle is forcefully displaced anteriorly (by failure of muscular co-ordination) out of the articular fossa but remains within the capsule of joint. The direction of condyle is almost always anterior, beyond the articular eminence.

Classification

- *Anterior*—it is more common than other two.
- *Posterior*—it is rare and results from the severe injuries which are sustained at the point of the chin or at the inferior border of the body of the mandible.
- *Central*—same as the posterior dislocation
- *Medial or lateral*—it occurs due to injury to the neck of condyle with its fracture. It is very rare.

Etiology

- *Extrinsic force*—it can occur under G.A. following extraction of teeth or the use of mouth gag, when muscle relaxant is used.
- *Intrinsic*—these are related to attempts of excessive opening of the mouth during eating or yawning and occasionally singing. These types of dislocation are sometimes called as *spontaneous dislocations*.
- *Occlusal disharmony*—in cases of *recurrent dislocation*, the etiologic factor is different, like occlusal disharmony producing muscle spasm.
- *Phenothiazine*—occasionally, action of phenothiazine group of drugs produces spontaneous dislocation of the mandible or spasm of the facial musculature.
- *Other causes* like epileptic seizure, yawning, taking too large bite of an apple and rarely, followed sneezing.

Clinical Features

Anterior dislocation

- *Site*—anterior dislocation may be unilateral or bilateral. In acute dislocation, there is a history of injury, gagging of molar teeth and anterior open bite.
- *Symptoms*—patient has great difficulty in swallowing and saliva drools over the chin. Pain in the region of temporal fossa and there is a depression where the condylar head is normally situated.
- *Signs*—the mandible is postured forward and movement is extremely limited. The condyle becomes locked anterior to the articular eminence and is prevented from sliding back by muscular spasm. When unilateral dislocation occurs, the teeth will be gagged posteriorly on the side of dislocation and the chin will be deviated towards the normal side.

Central dislocation

- *Cause*—the head of the condyle is forced through the floor of the articular fossa, into the floor of middle cranial fossa. In this case, there may be damage to the articular surface of the condyle and fracture of the neck.
- *Neurological signs*—neurological signs like the cerebral contusion, facial nerve paralysis, deafness and bleeding from the ear may also be present.

Posterior dislocation

- *Cause*—it results from severe injury, which forces the mandible backwards, so that the condyle penetrates the tympanic plate of the temporal bone. When the upward and backward thrust is applied to the chin, posterior dislocation occurs.
- *Age*—it is more common in elderly people as they have increased gonial angle, which leads to more posterior displacement of the condyle than in the case of an individual having a smaller angle.
- *Symptoms*—there may be tenderness over the affected TMJ, limited mouth opening, anterior open bite and laterognathism.

Radiographic Features

- *Anterior dislocation*—it is difficult to detect radiographically, as there is a wide variation in anterior condylar movements. Condyle is locked in front of the articular disc. Condyle is high on the anterior surface of the eminence and is well up in the infratemporal fossa and stayed there when the patient have closed their mouth.
- *Central dislocation*—radiologically, the anatomy of the articulation is seen to be altered, so that neck of condyle occupies a too high position in relation to the articular fossa.

- *Posterior dislocation*—radiologically, the anterior portion of the articular fossa is empty and the condyle is seen too far posteriorly. The neck of the condyle may appear short, if the head of condyle maintain its abnormal position. In such a case, the condyle may be seen partly covered by the more radiolucent external auditory canal. In cases when there is posterior dislocation into the tympanic plate, but has been subsequently reduced, it may be possible to identify the damage to the plate in good quality radiograph.

Diagnosis

- *Clinical diagnosis*—anterior open bite with gagging of molar teeth will aid in diagnosis.
- *Radiological diagnosis*—empty articular fossa space will diagnose this condition.

Management

- *Reduction of dislocation*—it can be done by the following
 - *Manipulation without anesthesia*—some type of sedation should be given to the patient before manipulation. Patient should be sitting on the chair with the operator in front. The thumbs covered with gloves should be pressed down over the buccal shaft area of the mandible, near the lower molar teeth and at the same time elevating the chin with fingers and pushing the entire mandible posteriorly and then upwards.
 - *With local anesthesia*—this treatment is based on the principle, that the dislocation is maintained by muscle spasm secondary to painful stimuli, arising from the capsule. The treatment consists of injection of local anesthesia (lignocaine hydrochloride) into the joint. After approximately one minute spontaneous reduction generally occurs without the necessity of manual reduction. Even in bilateral dislocation, unilateral injection is adequate. This is due to the elimination of neural reflex which extends over the muscle bilaterally and patient can close the mouth to normal position.
 - *Under general anesthesia, with the aid of muscle relaxant*—if the above mentioned method fails and the patient is unduly apprehensive then this method is used. Postoperatively, the jaws should be immobilized for 10 to 14 days, this help the inflammation and edema to subside.

Subluxation (Hypermobility)

It is the unilateral or bilateral positioning of the condyle anterior to the articular eminence, with repositioning to normal accomplished physiologic activity. It is self reducing

incomplete dislocation, which generally follows stretching of the capsule and ligaments.

Etiology

- *Long continuous opening of mouth* in the dental chair or singing, yawning or sleeping on one arm in bed.
- *Oral surgical procedures* excessive movement apparently causes stretching of the joint ligament or rupture of the external pterygoid attachment to the meniscus.
- It may follow the chronic degenerative changes of *osteoarthritis*.
- It may be a manifestation of an underlying *psychiatric problem*, which may be manifested by minor trauma.
- Use of *phenothiazine* derivatives by surgeons may also be responsible (due to hypersensitivity to the drug), it returns to normal after anti-histaminic therapy.

Clinical Features

- *Symptoms*—cracking noise, temporary locking of the condyle and immobilization of the jaw. Patient describes weakness of the joint while yawning. Pain is associated with last few millimeters of mouth opening.
- *Signs*—the condyle may get locked when the mouth is opened widely and upon closing, it will return with a jumping motion, accompanied by a sound caused by movement of the condyle over the articular eminence. On palpation 'click' on opening and sliding of condyle over the articular eminence, are common.

Radiological Features

Excessive excursion of the condyle from rest position to the position when jaw is opened wide (**Fig. 25-36**).

Fig. 25-36: Subluxation of TMJ observed on panoramic radiograph (Courtesy Dr Tapasya Karamore).

Diagnosis

- *Clinical diagnosis*—cracking noise will temporary locking of condyle will give clue to diagnosis.
- *Radiological diagnosis*—excessive excursion will be seen radiologically.

Management

- *Conservative method*—here, the objective is to achieve shrinkage of the capsule by a sclerosing agent, which will cause fibrosis of the capsule. It will limit the condylar excursion without deleterious effects on motion and cartilaginous part of the articulating surface of the condyle. The solution used is 5% sodium psylliate or 5% intracaine in oil base. A mixture of equal parts of 0.5% of eucupine in oil and 5% aqueous solution of sodium psylliate has an additional effect. It may be necessary to repeat the injection every 2 to 3 weeks, till fibrosis occurs.
- *Surgery*—insertion of bone graft is done. The joint is exposed; a vertical incision is made in the outer side of the capsule. The edges are overlapped and then sutured so as to tighten the capsule in the anteroposterior plane. After 7 days of intermaxillary fixation, clicking and subluxation will be relieved. Shortening of the temporalis tendon also relieves subluxation.

Internal Derangement or Disc Displacement

Here, the disc is abnormally located in relation to other components of the joint. It is usually displaced antero-medially. In some rare cases, disc may be displaced posteriorly. Most of the cases of disc displacement occur due to microtrauma from bruxism or clenching.

It can be defined as a malrelationship of the meniscus to the condylar head and articular eminence, where an alteration of its attachment allows the meniscus to assume an abnormal position.

Classification

- *Anterior displacement with reduction (Fig. 25-37)*—In it, as the condyle moves forward, it snaps under the posterior edge of disc producing an audible click and on closing the condyle may again snap under the posterior edge of the disc producing another click.
- *Anterior displacement without reduction*—There is no reduction of condyle in the mandibular fossa in closed position.
- *Posterior disc displacement*—condyle slip over anterior rim of disc during opening.
- *Disc displacement with intermittent locking.*
- *Disc displacement with perforation.*

Etiology

- *Articular surface remodelling*—it occurs due to combination of articular surface remodelling, disc deformation and displacement of either the condyle or the disc from an ideal relationship, which leads to jamming of the disc.

Fig. 25-37: Double contrast CBCT arthrography—it demonstrated anterior displacement of the disc without perforation and dilation of the superior joint space. Also, demonstrates multiple loculi in the anterior region of the joint space (Courtesy Kazuya Honda, Japan).

- *Articular eminence*—very steep articular eminence increases the risk of disc displacement.
- *Disc morphology*—if the morphology of the disc is altered and if the discal ligaments are elongated, there is increased risk of disc displacement.
- *Trauma*—trauma due to malocclusion results in the spasm of the lateral pterygoid and produces a series of changes.

Pathogenesis

- *Early changes*—Increased muscle tone of the lateral pterygoid → it tends to pull the meniscus anteromedially to the condylar head → the meniscus will move anterior to the condylar head → a click or pop will then occur on early opening as the condylar head reseats into the thin central portion of the meniscus → this type of joint noises occur in early stages of joint disease and can be corrected by relieving the muscle spasm.
- *Creation of freely moving disc*—discal ligaments are not elastic and hence once elongated; they generally remain at that length → the elongated discal ligament and the continuous muscle pull due to spasm results in freely moving disc on the articular cartilage.
- *Alteration of joint function*—if the posterior border of the disc becomes thinned and the retrodiscal laminae and lateral discal ligament becomes elongated → the disc can be translated across the articular surface of the

condyle—this translatory movement between the disc and the condyle is abnormal—once the disc is displaced anteromedially, normal joint function is altered.

- *Functional displacement*—at rest, the resistant force provided by the superior discal lamina will act and hence the condylar head will be positioned on the posterior border of the disc (known as functional displacement). Patient has feeling of tightness at this stage. When the person bites, the muscle pull further stretches the disc, causing arthralgia pain.
- *1st click*—in the closed joint position, the condyle articulates on the posterior border the disc. During opening, the condyle moves forward along with the disc. During this opening movement, the disc suddenly moves posteriorly, so that the condyle establishes a normal relationship with the intermediate zone of the disc. This sudden movement between the condyle and the disc results in clicking sound.
- *Reciprocal click*—if the condition persists, then there is elongation of the retrodiscal lamina. At this stage, during closing movements, the condyle moves the intermediate across the posterior border of the disc and just prior to the closed positions a second click is heard. This stage of derangement is called as the reciprocal click.
- *Anterior dislocation with reduction*—the patient can open the mouth to a certain extent at which they have a feel of locking. When the patient moves the jaw away from the painful side, opening is suddenly possible as the jaw suddenly becomes free with a pop. The meniscus is present anterior to the condylar head in the closed position. During mouth opening, the meniscus is pushed in front of the condyle until it mechanically blocks any further excursion. In order to reduce the dislocation, the patient needs to move the condylar head in the direction taken by the meniscus under the influence of the muscle. As the normal relationship is established, full opening is possible. When the mouth is opened, in disc dislocation, the condyle moves onto the posterior border of the disc. This creates jamming or catching sensation during opening. In some instances, the patient can move the mandible medially or laterally and abruptly move the condyle over the intermediate zone of the disc. During jaw movements, the disc returns to the normal position with the condyle.
- *Anterior dislocation without reduction*—in the next stage, due to continuous stretching caused by dislocation, soft tissue degeneration of the joint takes place and the meniscus becomes distorted and hypertrophied. The remaining elasticity of the bilaminar zone is lost and the meniscus remains anteromedially blocking forward the translation of the condylar head. This results in restricted movements and reduction is no longer possible.
- *Perforation of the disc*—due to continuous stretching, the condylar head is positioned on the retrodiscal tissues.

Due to pressure, tissue breakdown begins with inflammation of the tissue, which is called as retrodiscitis. Due to attenuation perforation occurs in the disc, leading to bone-to-bone contact, which ultimately results in osteoarthritis.

- *Disc dislocation*—if the posterior border of the disc becomes thinner and the retrodiscal lamina and collateral ligament become more elongated, the disc can slip anteriorly through the discal space. This is known as disc dislocation, as there is loss of contact between the articular surfaces of the condyle and the disc.

Clinical Features

Anterior disc displacement with reduction

- *Symptoms*—during the disc dislocation, the condyle may articulate on the retrodiscal tissue and may cause pain.
- *Signs*—on physical examination, the joint is tender and reciprocal audible clicking is heard. The jaw is deviated towards the side of the click, till the click occurs and then returns to the midline (**Figs 25-38A and B**).

Figs 25-38A and B: Deviation of jaw on right side in disc displacement with reduction.

Anterior disc displacement without reduction

- Patient who experiences repeated disc dislocations with reduction may further elongate discal ligament and retrodiscal lamina. Often, elasticity of the retrodiscal lamina is lost.
- *Closed lock*—if the condyle moves forward but the disc is not returned to its normal relationship between the condyle and fossa, a condition known as dislocation without reduction occurs. It is also called as closed lock.
- *Symptoms*—there is joint pain, limited opening, previous clicking with intermittent locking and sensation of something in the joint. The joint locks during opening of the mouth.
- *Signs*—there is joint tenderness with deviation towards the affected side. Terminal stretching produces increased joint pain.
- *Mouth opening*—there is limitation of lateral movement in the joint.

Disc displacement with perforation

- *Symptoms*—there is joint pain, clicking with intermittent locking and closed lock. There is also limited opening.
- *Signs*—crepitus and grinding noise. There is also joint tenderness.

Posterior disc displacement

- *Occlusal derangement*—sudden inability to bring upper and lower teeth tooth in maximal occlusion.
- *Pain*—there is pain in the affected joint when teeth are tried to bring in occlusion.
- *Forward displacement*—there is forward displacement of mandible on the affected side.
- *Restricted lateral movement*—there is restricted lateral movement to the affected side.
- *Mouth opening*—there is no restriction of mouth opening.

Radiographic Features

- *Plane radiography*—they are not diagnostic; except in cases of perforation of the disc, where there is evidence of degenerative changes in the joint.
- *Arthrogram*—arthrogram is useful in studying the changes.
- *MRI*—in anterior disc displacement, posterior band of the disc located anterior to the superior portion of the condyle is seen in closed mouth sagittal image. In some cases bone marrow edema can be seen (Figs 25-39 and 25-40).

Diagnosis

- *Clinical diagnosis*—clicking sound while opening and closing the mandible with pain in TMJ area.
- *Radiological diagnosis*—MRI is useful in the diagnosis of disc displacement.

Figs 25-39A and B: (A) Axial section, closed mouth, anteriorly displaced disc. (B) Axial section, open mouth, anteriorly displaced disc, but normal disc condyle relationship (Courtesy Dr Avinash Kshar and Dr Umarji, Government Dental College and Hospital, Mumbai).

Management

- *Bite plane appliance*—it involves one of the bite plane appliances that position the mandible so that the mouth remains slightly open vertically and is placed anteriorly to maintain the disc in a normal relationship to the condyle. Maxillary and mandibular appliances can be used for maintaining the disc reduction during function. The evaluation and adjustment in the appliance should be made monthly, till the condyle return to normal hinge position. TMJ should be stabilized in the position for two months by maintaining the patient on splints.
- *Occlusal adjustment, restorative and orthodontic treatment*—next phase is of occlusal adjustment, restorative treatment and orthodontics or all the three can be done.
- *Surgical treatment*—it is indicated in those patients who have chronic internal derangement, have failed to respond to non-surgical treatment. It includes

Figs 25-40A and B: Coronal section, closed mouth, laterally displaced disc (Courtesy Dr Avinash Kshar and Dr Umarji, Government Dental College and Hospital, Mumbai).

- **Disc repositioning procedure**—in this, there is removal of tissues from the posterior attachment of the disc with repositioning of disc in its normal position. It is sometimes combined with high intracapsular condylar reduction or an articular eminence re-contouring.
- **Menisectomy**—when it is not possible to repair the disc, interposition material is placed.
- **Postoperative physiotherapy**—postoperative physiotherapy is advocated to establish full range of motion. Bite plane appliance is used for a week followed by occlusal adjustment.

Adhesions

The movements between healthy articular surfaces occur without friction. Changes in the articular surfaces and synovial fluid can drastically change this frictionless system. This sticking of articular surfaces has been called

as *adhesion*. Adhesions can occur in either superior or inferior joint space and can occur with or without disc derangement. Adhesion can begin after prolonged static loading of the joint. The patient wakes up with limited jaw movement. As the patient attempts to move the mandible, a single click is felt (representing freeing of adhesion) and then, the normal range movement is restored. The click only occurs once and cannot be repeated without prolonged period of static loading. Adhesion are best demonstrated on arthroscopy (**Fig. 25-41**).

Fig. 25-41: Arthroscopic observation—band-like fibrous adhesion is observed in the posterior articular cavity (Courtesy Kazuya Honda, Japan).

Metabolic Disorders

Gout

It is a chronic metabolic disorder characterized by acute exacerbations of joint pain and swelling associated with an elevated blood uric acid and deposition of crystals of monosodium urate.

Various drugs like thiazide diuretics, operations, trauma, alcohol and rapid weight loss can predispose to this disease.

Clinical Features

- **Age and sex distribution**—seen in middle age with equal sex distribution. It has a hereditary tendency.
- **Sites**—initially, metacarpophalangeal joints are commonly involved. Later foot, ankles, hand, wrist and elbow may be affected.
- **Symptoms**—there is excruciating pain, which may be worsen at night. Sometimes, it is associated with anorexia, fever and general malaise.
- **Progress**—joint returns to normal after few days, with desquamation of the overlying skin.

- *Chronic cases*—as the disease becomes chronic, pain and stiffness persist, with irregular swelling. Tophi are found in cartilage of the ear, nose or eyelids. In half the cases, palms of hands may show white streaks along the creases.
- *TMJ involvement*—sudden excruciating pain in the TMJ, followed by rapidly developing swelling. There is also tenderness of the affected area with limitation of movements. Deviation to the affected side while opening the jaws.

Radiographic Features

- *Punched out lesion*—punched out areas in the carpal bone of the hands. In TMJ also, punched out radiolucency can be seen on the condylar cartilage.
- *Destruction of cartilage*—severe destruction of the cartilage can also be seen in some areas.
- *Calcification in the joint*—there is calcification within the joint spaces which may be subtle or massive.

Diagnosis

- *Clinical diagnosis*—multiple joint involvements. Tenderness on the TMJ area can diagnose the disease.
- *Radiological diagnosis*—punched out lesion with calcification in the joint.
- *Laboratory diagnosis*—articular cartilage reveals white chalky deposits. This deposit is also often found in the synovial and adjacent tissues. The cartilage may be fragmented. Crystalline deposits of uric acid are seen. This is followed by small accumulations (*microtophi*) with surrounding granulomatous foreign body reaction.

Management

- *Diet*—diet should be low in uric acid and fat, i.e. sweetbread, meat, extract peas, beans.
- *Uricosuric agents*—increased elimination of uric acid by uricosuric agents like colchicine 0.5 mg every 2 hourly, to a maximum of 6 mg in 24 hours.

Neoplastic Disorders

Benign Tumors

Benign tumors reported are osteoma and osteochondroma.

Clinical Features

- *Symptoms*—there is stiffness of the joint with facial asymmetry.
- *Signs*—deviation of mandible on the affected side. Disordered occlusion, little movement of the condyle on palpation. There are restricted movements of TMJ.

Radiological Features

- *Appearance*—there is bony mass protruding from the condyle (Figs 25-42 and 25-43).

Fig. 25-42: Chondroma of condyle showing radiopaque lesion on right condyle.

Fig. 25-43: Osteoma of condyle on right side (Courtesy Dr Datarkar).

Management

- *Surgical*—surgical excision of the tumor and orthodontic treatment, to re-establish the occlusion.

Malignant Tumors

Types

- *Intrinsic*—it arises from the bone of the condyle, articular fossa and the joint capsule or the articular disc. It includes chondrosarcoma and synovial sac sarcoma.
- *Extrinsic*—the tumors which extend from outside of TMJ, e.g. neoplasm of the parotid gland.

Clinical Features

- *Age and sex*—age of incidence from 17 months to 68 years with male to female ratio being 1:1.
- *Symptoms*—pain on full opening of the mouth and diminished hearing. Swelling of the TMJ is present. Swelling may be huge to cause facial asymmetry.
- *Signs*—the tumor may be fixed to deep structures. Deviation of the mandible to the unaffected side. There is also malocclusion (Fig. 25-44).

Fig. 25-44: Huge swelling seen on right side of patient due to chondrosarcoma of condyle.

Radiological Features

- *Appearance*—irregular destruction of bone in condylar region is present (Fig. 25-45).

Management

- It can be treated by surgery, chemotherapy, radiotherapy and combination therapy.

Fig. 25-45: Irregular destruction seen in the condylar area due to chondrosarcoma.

Miscellaneous Disorders

Synovial Chondromatosis

It is a benign chronic progressive metaplasia that will not resolve spontaneously. Although it is non-neoplastic, it may resemble a malignant condition histologically. It is also called *chondrometaplasia*. It denotes the condition whereby a cartilaginous focus develops within the synovial membrane of the joint.

Pathogenesis

- *Predisposing factors*—trauma may be a predisposing factor, other factors are malocclusion, occlusal habits, and subluxation or tension sites.
- *Metaplasia of mesenchymal cell*—this is generally believed to occur through metaplasia of mesenchymal cell rests in the underlying connective tissue of the membrane.
- *Formation of metastatic foci*—there is formation of metastatic foci.
- *Detachment of metastatic foci*—foci are detached from the affected membrane and become cartilaginous, and forms mobile bodies within the joint cavity.
- *Calcification of cartilaginous foci*—many of these cartilaginous foci then undergo calcification. These joint bodies acquire a perichondrium, which enables them to grow by proliferation of chondrocytes.

Clinical Features

- *Age and sex*—female to male ratio is 3:1 with greatest incidence at 40-60 years of age.
- *Site*—this affect large joints like knee, elbow, hip and shoulder. This disease is also present in temporomandibular joint.
- *Symptoms*—facial pain, limitation of motion and deviation towards the affected side.
- *Signs*—crepitus, preauricular swelling, enlarged joint with effusion and local tenderness.

Radiographic Features

- *Loose bodies*—this consists of rounded /irregular shaped radiopaque structure in the joint (Fig. 25-46).
- *Joint space*—there is irregularity in the joint space. Joint space is also widened.
- *Condyle*—condylar head is also irregular.

Diagnosis

- *Clinical diagnosis*—it does not show any diagnostic features
- *Radiological diagnosis*—radiopaque loose bodies seen in the joint space.

Fig. 25-46: Loose bodies seen as rounded shaped in arthroscopic view (Courtesy Dr Honda).

- *Laboratory diagnosis*—cartilage shows hyperchromatic and binucleated chondrocytes.

Management

- *Surgical*—loose bodies should be removed.
- *Synovectomy*—total synovectomy can be done to prevent recurrence.
- Removal of metaplastic foci and synovectomy are the preferred treatment.

Drug Induced Disorders (Steroids)

Corticosteroids induce mandibular osteoarthritis. The manifestations depend on the dosage, potency and duration of exposure to excessive steroids. Impaired connective tissue function may lead to calcification of the cartilaginous matrix, resulting in osteoarthritis like changes.

Lesions develop initially in the midst of condylar cartilage and then spread to involve the articular cartilage. The effect of steroids on the chondrocyte is inhibitory in nature. The catabolic activity of steroids on the condylar cartilage is due to its inhibitory effect on DNA and RNA synthesis in chondrocytes, with subsequent interference in protein synthesis.

In addition, triamcinolone was found to enhance the synthesis and secretion of parahormone in various experimental animals and thereby could elicit the degenerative changes in the joint tissue.

TMJ Dysfunction Syndrome or Myofascial Pain Dysfunction Syndrome

When muscle spasm develops, dysfunction as well as pain occurs and the condition usually is designated as MPDS. It is initiated as spasm of one or more masticatory muscle.

Etiology

- *Abnormal occlusion*—in case of painful and potentially damaging contact in the occlusion, persons make modifications in the pathway of closure. These corrective movements of the mandible, during closure may elicit muscle strain and spasm, which in turn results in an abnormal pressure on the TMJ.
- *Tooth muscle theory*—occlusal interferences cause an altered proprioceptive feedback, leading to incoordination and spasm of some of the muscles of mastication.
- *Prosthetics problems*—some authors think that interceptive contact, due to faulty complete and partial dentures, over closure, bilateral loss of molar teeth, and increased vertical dimension in partial and complete denture may lead to TMJ dysfunction. There is a change in the myotactic stretch reflex in all above mentioned conditions, which support the view that the TMJ dysfunction can result from over closure.
- *Orthodontic problems*—malocclusion leads to TMJ dysfunction.
- *Emotional problems*—pattern of over behaviors relating to care of teeth, food habits may lead to TMD (temporomandibular dysfunction). Oral habits can cause structural damage or persistent pain. Dysfunction of autonomic nervous system resulting from anxiety and eventually producing structural changes in the end organs.
- *Psychophysiologic theory*—the masticatory muscle spasm is responsible for the signs and symptoms of pain dysfunction syndrome. Persistent myospasm also can cause two other organic changes, namely *degenerative arthritis* which can arise from continued jaw function with condyle in an abnormal position and *contracture* degenerative changes in muscle, that accompanies long term spasm. Spasm can be initiated by muscular over-extension which is caused by:
 - *Dental restoration*—by dental restorations or fixed and removable prosthesis that encroach on the intermaxillary space.
 - *Tooth loss*—by muscular over-contraction which is caused by bilateral loss of posterior teeth.
 - *Denture wearer*—by settling of partial denture or in patients wearing complete denture.
 - *Oral habits*—by muscle fatigue which is caused by oral habits such as clenching or grinding of the teeth.
 - *Dental irritation*—it can be initiated by dental irritation like maloccluding restorations or an over hanging margin.
- *Joint problems*—hypermobility caused by lax ligament may give rise to symptoms of TMJ dysfunction. It has been also shown that patient with steep angulations of articular eminence are more predisposed to the TMJ dysfunction syndrome. Degenerative changes secondary

to chronic para-functional habits or over-closure due to bilateral loss of molar teeth result in TMJ dysfunction syndrome.

Pathogenesis

- During muscle contraction, the energy is released → there is formation and accumulation of lactic acid → which in turn causes changes in osmolality which results in decrease in the pH → it makes the muscle receptor prone to impulse excitation as their critical firing level is impaired → decrease in pH and lactic acid itself causes infusion and effusion of histamine, bradykinin and serotonin and other amines into the area → it causes pathological muscular derangement → these particular areas of muscular derangement are called as 'trigger zones' → it is a hypersensitive area from which impulse bombards the CNS and gives rise to referred pain.

Classification

- *Spasm of lateral pterygoid muscle*—it occurs when the teeth are brought into maximum intercuspation and with extended translatory movement. Pain reduces on biting against a separator (as it prevents the intercuspation required to stretch the spastic muscle). It is accompanied by acute malocclusion expressed as anterior displacement of the mandible.
- *Spasm of elevator muscles*—it occurs when biting and chewing efforts are made and while opening the mouth. Pain is not decreased on biting on a separator and is accompanied by trismus with little or no restriction of excursive movements.
- *Spasm of lateral pterygoid and elevator muscles*—in it, pain occurs while biting, chewing, opening, maximum intercuspation and extended translatory movement. Pain is not affected by biting against a separator, except for some decrease of pain with maximum intercuspation and is accompanied by acute malocclusion, trismus but with little or no restriction of excursive movements.

Clinical Features

- *Age and sex distribution*—it is seen in middle age group with more predilections for women.
- *Onset*—it occurs in episodes of several times a day, at times, with extended symptom free intervals. Usually episodes are seen during increased emotional tension, resulting in increased intra-articular pressure in the joint.
- *Symptoms*—there is masticatory pain which occurs due to myalgia, arthralgia or from both. Pain is localized to preauricular area but can be radiated to temporal, frontal, and occipital region. There is difficulty in chewing and restriction of mandibular excursion. Patient also complains of noise on rubbing, grinding, clicking, and

popping snapping sounds on mandibular movement.

- *Tinnitus*—patient may complain of tinnitus (ringing in ear) or otalgia (pain in ear) or toothache. The reason behind tinnitus is that bilateral molar loss causes distal condylar movement and direct pressure on the eustachian tube with impingement on the auriculotemporal nerve, which is responsible for the ear symptoms, i.e. tinnitus.
- *Hearing loss*—it may cause irritation of the chorda tympani nerve, resulting in partial or total hearing loss.
- *Signs*—restriction of opening and protrusion may be accompanied by deflection of the mandibular incisal pathway. There is also soreness of muscle, when palpated. Myofascial trigger zones are stimulated by pressure and produce referred pain.
- *Myospasm*—muscle splinting can lead to CNS induced muscular contraction. In some cases, myositis may also occur.
- *Other features*—oral or para-functional habits, such as bruxism, present as indentation on lateral borders of the tongue, ridging of the buccal mucosa and extensive attrition of teeth.
- *Involvement of various masticatory muscles and their clinical effects.*

Muscle	Pain refers to	Clinical effect
Temporalis	Temple, maxillary teeth TMJ	Restriction of mandibular opening, ipsilateral deviation of mandible, deviation of interocclusal space
Masseter	Mandible, maxillary molar, TMJ, ear	Same as above
External pterygoid	TMJ	Contralateral deviation of the mandible, protrusion of condyle, acute malocclusion
Internal pterygoid	TMJ, retromandibular area, tongue	Restriction of mandibular movements, contralateral deviation of mandible

Laskin's Diagnostic Criteria for MDPS

- *Four cardinal signs*
 - *Unilateral pain*—it is generally a dull ache in nature felt in the ear or the preauricular area or at the angle of the mandible. The pain is more often worse on arising in the morning or relatively mild in the morning, but gradually becomes worse as the day progresses.
 - *Muscle tenderness*—the most frequent areas are the neck of mandible and in the region distal and superior to the maxillary tuberosity.
 - *Clicking*—clicking or popping noise in the TMJ.
 - *Limitation of jaw function*—limitation of jaw function or deviation of the mandible on opening.

- *Negative characteristics*
 - *No radiographic evidence*—absence of radiographic or biochemical evidence in the TMJ.
 - *No tenderness*—lack of tenderness in TMJ area, on palpation via the external auditory meatus.

Management

Education regarding present illness

- *Re-educate* the patient about the mechanism involved and factors causing or aggravating the disorder. The patient is convinced about the disease status.
- *Reassurance*—the patient is assured of the benign character of the myospasm. The patient should be explained that there will not be any residual deformities after the treatment.
- *Suggestion*—may act as a powerful tool in the treatment. The calm attitude of the clinician and reassurance given suggests the patient that recovery is bound to occur. Let the suggestions act in a natural quiet fashion rather than trying to use it in some spectacular ways.

Muscle relaxation techniques and muscle exercise

- *Tongue exercise*—the patient is asked to keep his tongue as posteriorly as possible, in contact with the palate, while keeping the mandible in a retruded position. In this exercise, mainly rotatory movements are performed.
- *Mouth opening exercise*—the patient is asked to open his mouth slowly, rhythmically, within the pain limit, 10 times in succession. Next, the patient is asked to repeat such exercises with the addition of one modification, i.e. voluntary resistance.
- *Voluntary resistance*—this technique is based on the physiologic principle of reciprocal muscle inhibition (reflex inhibition), e.g. on depressing the mandible, the contraction of the depressor muscle group causes an inhibition of the elevator muscles. Thus, if a muscle is subjected to a greater degree of inhibition, its relative relaxation will increase proportionately. This muscular relaxation will increase circulation to the antagonist system. It is during this period of active reflex inhibition, that the noxious stimuli present in and about the trigger zone can be eliminated. Resultantly, the inter-muscular blood vessels get dilated. As more muscle fiber areas relax and fewer remain in spasm, the patient evidences gradual, painless and rhythmic mandibular movements.

Pharmacotherapy

- *Pain control*—it is usually achieved by analgesics. Most widely used analgesic is salicylates, the commonest being aspirin.
- *Tranquilizers*—there are major and minor tranquilizers. The tranquilizers used in major psychoses, like

phenothiazine derivatives, having calming effect in anxiety states associated with neurotic personality. It relieves tension, fear and produces a sense of well being.

- *Antidepressants*—they are mood elevators like monoamine oxidase inhibitor, lithium carbonate and caffeine.
- *Sedative*—sedatives are the drugs that reduced excitement.
- *Hypnotic*—hypnotics produce sleep which resembles natural sleep.

Biofeedback

- *EMG biofeedback device*—the most commonly used biofeedback device is electromyographic (EMG) biofeedback machine. The device senses cutaneous electrical output. Every time the muscle contracts and electrical current is given off, which diffuses outward and may reach the skin. Current from the muscle nearer to the skin is much earlier to detect than current from deeper muscles. Muscle gives off a specific frequency of electrical output. The biofeedback elaborately gauges the amount of amperage and voltage. This method is non-invasive and painless.
- *Temperature biofeedback*—the temperature biofeedback accounts of placing a delicate thermometer on the skin. The temperature is measured in tenth of degree centigrade. The higher the temperature, the higher the pitch of sound. When there is poor circulation, individual can increase the temperature by this method.

Bruxism prosthesis

- *Soft mouth guard*—it is a bruxism guard made up of soft resin. It may be fashioned for either upper or lower teeth and is designed even for centric contact of all the teeth.
- *Anterior occlusion prosthesis*
 - *Lucia jig*—it consists of a smooth acrylic rim placed on the lingual aspect of the upper incisors. It should be complete enough to provide complete posterior disocclusion.
 - *Anterior bite plate*—this appliance does not produce posterior contact and hence can be used in patients with bruxism. It should not be used for more than one or two weeks as than it may raise the bite.
- *Mandibular posterior coverage*—it covers the posterior teeth of the mandible, when the jaws are closed. It causes bilateral, single point contact on the most distally placed tooth. It is made up of acrylic or metal.
- *Complete maxillary or mandibular coverage*—it covers all occlusal surfaces in either maxillary or mandibular arch. By gripping all the teeth in one arch, it acts as a true splint, preventing the tooth movement and minimizing the number of posterior teeth occluding. In addition, anterior guidance will provide posterior disocclusion in all eccentric movements.

Psychotherapy

- *Stress impasse stages*—the stress impasse stages in the TMJ syndrome are characterized by three distinct steps based on the evolution and progression of the disease.
 - *Stress impasse I*—conflict from personality fixation, usually in adolescents, chronic symptoms develop (bruxism, clenching, grinding).
 - *Stress impasse II*—onset of acute symptoms (pain, jaw clicking).
 - *Stress impasse III*—severe symptoms resulting in TMJ damage.
- *Treatment plan*—the treatment plan includes a three stage programme, which will include basic relaxation exercises, sleep preparation and containment strategies for worry, grief and guilt.

Physical medication

- *Hot packs*—the one of moist heat is advantageous. Heat should be applied directly to the trigger zones. Temperature changes can alter the amount of vasodilation substance held within the tissue spaces. The patient should be instructed to place hot fomentation over a particular area for not less than 10 minutes, preceding the therapeutic exercises. Woolen cloth soaked in boiling water is usually used.
- *Massage*—it provides relief from muscle spasm and also improves the local circulation, by reducing the local biogenic amines.
- *Diathermy and ultrasound*—this is a more effective method for the treatment of myospasm of deeper muscles. It produces heat and thus improves the local circulation.
- *Electrical stimulation (TENS)*—tetanizing and sinusoidal current is used in this therapy. It is another effective way to break acute painful muscle spasms. Electrodes are placed over the most painful areas and then tetanizing current is turned on gradually, until good contraction of the affected muscle has been obtained. Current should not exceed the tolerance level. The current is left for 120 minutes. Then with the electrode remaining in the same position, the tetanizing current is switched off and sinusoidal current is gradually applied, till good contraction is obtained.
- *Oral myofunctional therapy* is a program to re-educate the muscles of the mouth and face to work in a balanced relationship. It includes breaking of a habit (Lip biting, tongue thrusting), proper feeding of infant and proper balancing of environmental forces. The appliances used are activator, bionator, Fränkel's appliance and oral screen.

Applied kinesiology

- *What is it*—dental Kinesiology is the study of motion and function of the jaws, oral musculature, the accompanying neurological, vascular and other support system network and the impact these muscle functions

and neurological dynamics have on dental and systemic health. Its basic application is for reduction and prevention of muscle spasm.

- Muscles are tested to identify the weak muscle. The clinician then uses various kinesiologic procedures to increase the stress resistance of the tensed antagonist muscle to a more optimum level.

Anesthesia

- *Muscle and fascia (trigger points)*—injection of local anesthetic agent into the painful trigger zones is therapeutically efficient. It permanently terminates the pain-spasm-pain cycle. Local anesthesia breaks the cycle by blocking the nerve impulse conduction and by eliminating pain from that area. Local anesthesia should be used without vasoconstrictor component, i.e. adrenaline. It is important to first isolate the trigger zone. Then, it is gently probed to reach for the most hyper-sensitive tissue. Once defined, slow infiltration of anesthetic solution is deposited. The patient is then instructed to begin a series of exercises.
- *TMJ (intracapsular and extracapsular)*—many a times, xylocaine is used in conjunction with injection of hydrocortisone for the intra-articular injection into the TMJ. 0.5 ml of 0.5% xylocaine is generally used.
- *Refrigerated spray*—vapocoolant spray, such as ethyl chloride or fluoromethane, is used to reduce muscle spasm by causing counter irritation. Since pain and temperature sensation travel by the same spinal pathways, it is theorized that response to pain impulse originating from the trigger zone, is completely inhibited and thus, inhibition of the vicious cycle is achieved. The spray is applied with a slow sweeping motion over the trigger points. Skin frosting should be avoided.

Other therapies

- *Hypnotherapy*—here, the patient's cooperation is essential and he should follow the suggestions of the hypnotist. It is an individual's belief that aids him in following the suggestions of the hypnotist. By this method, muscle relaxation is achieved.
- *Acupuncture*—it is a simple, effective and conservative pain control modality. It is accomplished by inserting needles into appropriate joints, at appropriate surfaces called as meridians. These meridian points are generally associated with major nerves, arterial pathways, joints and fascial planes. Rotating a sharp, small needle between the fingers rapidly and pressing it through the skin rapidly, in the acupuncture point provides relief from pain. The patient may feel soreness, distension, heaviness or numbness, if it is placed into so called acupuncture point. However, it should be kept in mind that this therapy is used only to give relief from pain and it will not remove the basic cause.

- *Surgery*—various surgical procedures like eminectomy, zygomectomy, menisectomy, high condylectomy with material interposed between the articulating surfaces and orthoplasty plus menisectomy are most frequently advocated.
- *Restoration*—faulty overfilled restorations should be removed to avoid interceptive contact. Sometimes, complete mouth rehabilitation is required to achieve centric occlusion.
- *Prosthodontic therapy*—it has been shown that overclosure due to bilateral loss of posterior teeth can cause TMJ pain. In such cases, bilateral fixed or removable replacement should be done to achieve normal vertical dimension.
- *Orthodontic therapy*—it is indicated in cross bite and traumatic bite. In patient with parafunctional habits, such as bruxism, night guard appliance should be given.
- *Orthognathic therapy*—when there is skeletal discrepancies causing malocclusion, orthognathic surgery is indicated.

Salivary Gland Disorders

Development of Salivary Gland

The three major sets of salivary gland—the parotid, submandibular and sublingual originate in a uniform manner by oral ectodermal epithelium buds invading the underlying mesenchyme.

- *Parotid gland*—the parotid gland develops in the lateral aspect of stomodeum. Parotid gland buds are the first to appear at the 6th week of intrauterine life, on the inner aspect of cheek, near the angles of mouth and grow back towards the ear. In the parotid and ear region, the epithelial cord of cells branches and canalizes to provide the acini and ducts of the gland. The duct and acinar system are embedded in a mesenchymal stroma, get organized into lobules and become encapsulated. The parotid gland duct, although repositioned, traces the path of embryonic epithelial cord in the adult.
- *Submandibular gland*—it develops in the floor of stomodeum. Submandibular gland buds appear in the 6th week of intrauterine life as a grouped series, forming epithelial ridges on the either sides of the midline, in the floor of the mouth. An epithelial cord proliferates back into the mesenchyme beneath the developing mandible to branch and canalize, forming the acini and ducts of submandibular gland. The mesenchymal stroma is separated off the parenchymal lobules and provides a capsule for the gland.
- *Sublingual gland*—it also develops in floor of stomodeum. It arises in the 8th week of intrauterine life, as a series of about ten epithelial buds, just lateral to the submandibular gland analogue. These branches and canalize to provide a number of ducts opening independently beneath the tongue.
- *Minor salivary gland*—minor salivary gland begins their development during the third month of life. These glands arise from the oral ectodermal and endodermal epithelium. *Labial glands* arise during the 9th week of intrauterine life and are morphologically mature by 25th week.

Classification of Salivary Glands

- *Exocrine glands*—these are the glands whose products are carried away by the ducts leading from the gland.
- *Mesocrine glands*—the secretory products pass through the cell walls losing the cytoplasm.
- *Serous salivary gland*—the salivary glands which produce a thin watery secretion are called as serous.
- *Mucus salivary gland*—these produce a thick, viscous substance called mucus.
- *Seromucus salivary gland*—salivary glands which produce serous and mucus in varying quantities.
- *Major salivary gland*—these are large salivary glands which are located outside the oral cavity and convey their secretions through their ducts.
- *Minor salivary gland*—these are smaller salivary glands confined to the mucus and submucus coat of the oral cavity.

Major Salivary Glands

Major salivary glands are parotid, submandibular and sublingual.

Parotid Gland

- *Location*—it comes from the word para—around and otic—ear. It is like an inverted flattened pyramid. It is the largest of the salivary glands weighing about 15 grams each. It lies between the mastoid process and vertical ramus of the mandible. The bulk of the parotid gland is situated in the retromandibular fossa (**Fig. 26-1**).
- *Shape*—it is wedge shaped, with the broad edge of the wedge lying subcutaneously and the apex lying deep between the parotid fascias. It is divided into superficial and deep lobes by the facial nerve and its branches. It forms an irregular lobulated yellowish mass, lying below the external acoustic meatus, between the mandible and

the sterno-cleidomastoid. A small part of it, more or less detached lies between the zygomatic arch superiorly and the parotid duct inferiorly is named '*accessory part*' of the gland.

- *Stensen's duct*—the parotid duct which is called as '*Stensen's*' duct is about 5 cm long and has thick walls. It emerges from the substance of the gland to course anteriorly until it reaches the anterior border of the masseter muscle at the point of upper and middle thirds. When it crosses the masseter muscle it receives the duct of the accessory lobe. Around the border of the masseter muscle, the duct turns sharply medially, often embedded in a furrow of the protruding buccal fat pad. In its medial course, the duct reaches the outer surface of the buccinator muscle, where it perforates in an oblique direction anteriorly and medially. It then runs for a short distance obliquely forward, between the buccinator and mucus membrane of the oral cavity and opens on the oral surface of the cheek, opposite the upper second molar.
- *Blood supply*—parotid gland is supplied by the external carotid artery and its branches near the gland.
- *Lymphatic drainage*—drains first to the parotid nodes and from there to the upper deep cervical nodes.
- *Nerve supply*—it is supplied by auriculo-temporal nerve, plexus around the external carotid artery and greater auricular nerve.

Fig. 26-1: Location of parotid and submandibular gland.

Submandibular Gland

- *Shape and size*—it is a round biconvex salivary gland situated in the anterior part of the digastric triangle. It is irregular in form and about the size of a walnut.
- *Location*—it is enclosed by two layers of deep cervical fascia. The inner surface of the submandibular gland is in contact with stylohyoid, digastric and styloglossus muscle, posteriorly and with the hyoglossus and posterior border of the mylohyoid muscle, anteriorly.

- *Wharton's duct*—the submandibular duct which is called as '*Wharton's duct*', is about 5 cm long and its wall is much thinner than that of parotid duct. It emerges from the middle of the deep surface, of the superficial part, of the gland. It runs forward, beneath the deep part of the gland, between the mylohyoid and hyoglossus muscle. It runs further forward between the medial surface of the sublingual gland and the genioglossus muscle and finally ends by opening into the summit of the sublingual papilla, situated in the floor of the mouth, on the side of the frenulum. The last few millimeters of the duct are often slightly widened.
- *Arterial supply*—the arteries supplying the submandibular gland are derived from the lingual and facial branches of external carotid artery.
- *Venous drainage*—it drains into facial and lingual vein.
- *Nerve supply*—its nerve supply is from the branches of submandibular ganglion through which it receives fibers from chorda tympani.
- *Lymphatic drainage*—passes to the submandibular lymph node.

Sublingual Gland

- *Location*—it lies above the mylohyoid and below the mucosa of the floor of mouth. It is medial to the sublingual fossa of the mandible, on either side of the symphysis menti and lateral to genioglossus muscle. It has about 15 ducts which open directly into the floor of mouth.
- *Bartholin's duct*—the duct of sublingual gland is called as '*Bartholin's duct*'. They are eight to twenty in number. Some of the smaller sublingual ducts open into the sublingual fold, in the floor of the mouth, on either side of lingual frenum. Some open into the submandibular duct and others unite to form the "*principle sublingual duct*" which opens in the floor.
- *Blood supply*—it is supplied by sublingual and submental arteries.
- *Nerve supply*—it is supplied by lingual and chorda tympani nerve.
- *Lymphatic drainage*—it passes to the submandibular lymph nodes.

Minor Salivary Glands

The minor salivary glands are located beneath the epithelium in almost all parts of the oral cavity. These glands usually consist of several small groups of secretory units, opening via short ducts directly into the mouth. The function of minor salivary glands is not really to produce saliva for mixing with food, but to secrete minor amounts of saliva onto the mucosal surface to keep the mucosa moist.

- **Labial glands**—they are found on the submucosa of upper and lower lips and opens onto the inner surface (Fig. 26-2). They are more numerous in the areas close to midline. The labial glands classically have been described as mixed, consisting of mucus tubules with serous demilunes.

Fig. 26-2: Location of labial gland.

- **Buccal glands**—they are found in inner cheek region. In the anterior part of the cheek, they are sparse and rather widely and irregularly spaced. They are usually described as continuation of labial glands, as they have similar structure. A group of these glands is situated at the lower posterior corner of the cheek which is called as the 'molar or retromolar glands'.
- **Palatine glands**—the palatine glands are located in soft palate and posterolateral part of hard palate (Fig. 26-3). They are pure mucus in nature. The excretory ducts may have an irregular contour and opening of the ducts in the palatal mucosa is large.

Fig. 26-3: Location of palatine gland.

- **Glossopalatine glands**—these are pure mucus glands. They are principally located in the region of the isthmus of the glossopalatine fold but may extend from the posterior extension of the sublingual gland to the glands of soft palate.
- **Gland of Blandin's and Nuhn's**—these are the anterior lingual glands. They are located near the apex of the tongue and are chiefly mucus in nature. They are covered by thin mucus membrane of the inferior surface of the tongue. It is compact package of smaller glands that open with several ducts on the inferior surface of the tongue.

- **Gland of von Ebner**—lingual glands of von Ebner are posterior lingual serous glands, located between the muscle fibers of tongue, below the vallate papillae.
- **Posterior lingual glands**—posterior lingual glands are located lateral and posterior to the vallate papillae and in association with the lingual tonsils. They are purely mucus in character.
- **Incisive gland**—the incisive glands are a small group of glands found on the floor of the oral cavity close to the insertion of the lingual frenum, behind the lower incisors (Fig. 26-4).

Fig. 26-4: Location of incisive gland on floor of mouth.

Saliva

Composition of Saliva

- **Source of saliva**—saliva is secreted by salivary glands: viz the parotid, submandibular and sublingual glands. These glands produce approximately 1.5 liters of saliva daily: 70% is from the submandibular glands, 25% is from the parotid glands and 5% is from the sublingual glands. Minor salivary glands located on the palate, buccal mucosa and tongue also produce modest amounts of saliva.
- **Normal stimulated flow of saliva**—the normal stimulated flow for different ages can be calculated with following equation:

$$0.78 \times \text{age} + 5.6 = \text{stimulated flow/15 minutes.}$$

5.6 – it is estimated stimulated flow of the infants

- **Composition of saliva**—saliva is slightly cloudy in appearance due to the presence of cells and mucin. Saliva is slightly acidic and the pH varies from 6.7 to 7.4, specific gravity is 1.002 to 1.012. The resting flow rate of saliva, on an average is about 0.3 to 0.4 ml/min. Saliva contains about 99.5% of water and 0.5% of solid.
- **Solid**
 - **Cellular constituents**—consist of yeast cells, bacteria, protozoa, polymorpho-nuclear leukocytes and desquamated epithelial cells.

- *Inorganic ions*—major (Na^+ , K^+ , Cl^- , HCO_3^-) and minor (Ca^{++} , Mg^{++} , HPO_4^- , I , Scn^- and F^-).
- *Secretory proteins and glycoproteins*—various enzymes, large carbohydrate rich protein or mucin, antibacterial substance, group of proteins involved in enamel pellicle formation and calcium phosphate.
- *Serum constituents*—albumin, blood clotting factor, B_2 microglobulin and immunoglobulin.

Collection Technique

Parotid Collector

- *Composition*—it was developed by *Lashley* in 1916. It makes possible the collection of parotid fluid uncontaminated by the oral content. It is composed of two concentric circles and is made of either plastic or metal.
- *Technique*—the center circle is designed to fit over the opening of Stensen's duct and is connected to a graduated collecting tube. The outer concentric circle is attached to a rubber bulb, which exhausts air from the outer circle, when collector is held in place and draws the cheek surrounding the opening of Stensen's duct into it.
- *Disadvantage*—due to different anatomy, it cannot be used in submandibular and sublingual gland.

Segregator

- *Composition*—it is developed by *Schneyer* which allows the collection of submandibular and sublingual gland. It is made up of plastic or metal. It must be constructed for each individual on the stone model. In it, preformed basic plastic collector is utilized.
- *Technique*—this plastic is covered with rubber base impression material and placed on the floor of mouth beneath the tongue. In 5 minutes, impression can be removed. A recess is then made in the impression, over the opening of Wharton's duct and plastic collecting tube is attached. The collector stays in position when the patient places his tongue against the lingual surface of the lower incisors.
- *Advantage*—it may be sorted and reused for the individual patient. It collects saliva from sublingual and submandibular ducts.

Collection of Whole Saliva

- *Stimulation of saliva*—for collection of whole saliva, stimulation of saliva is to be done by asking the patient to suck on sour candy or sour grapes. You can also ask patient to chew on cimer paraffin or rubber bands. A more standardized procedure is to swab a solution of 2% citric acid on the back and side of tongue at 15 seconds

intervals. Secretion can be obtained by draining, spitting and suction.

- *Draining*—in this, the subject is placed with his head inclined forwards, so that saliva will collect in the anterior floor of the mouth. The position of the patient allows the saliva to flow over the lip, where it is collected by funnel.
- *Spitting*—in this, the subject actively spits into the collecting funnel at regular intervals.
- *Suction*—saliva ejector is applied orally in the area of lower incisors and the aspirated fluid is collected after the patient has remained quits for fixed time periods.

Function of Saliva

- *Digestive function*—it participates in digestion by providing fluid environment for solubilization of food and taste substance, through action of enzyme amylase and lipase. It helps in formation of food bolus, which is readily chewed.
- *Lubricating*—it keeps the oral tissues moist and facilitates swallowing and speaking. Mucus glycoproteins provide lubricant for the movement of oral tissues against each other and protection from chemical and thermal insults.
- *Protection of teeth*—it helps to protect the teeth from dental caries by means of, both, cleansing and buffering action of saliva. It also controls the calcium and phosphate concentration in the saliva and around the teeth.
- *Protection from injury*—it dilutes hot or irritant substance and thus prevents injury to mucus membrane.
- *Maintenance of mucus membrane integrity*—the salivary mucin possesses rheological properties which include low solubility, high viscosity, elasticity and adhesiveness which enable them to concentrate on the oral mucosal surface. They provide an effective barrier against desiccation and environmental insult. Salivary mucin binds water effectively and hence serves as natural 'water proofing' and helps to maintain these tissues in a hydrated state. The glycosylated mucins of saliva are resistant to proteolysis. This maintains the integrity of mucus membrane by neutralizing the bacterial and PMN proteases.
- *Antibacterial properties*—several salivary substances are capable of inhibiting the growth of microorganisms. They are glycoproteins, antibacterial protein, i.e. lysozyme, immunoglobulin IgA, IgG, IgM and lactoferrin.
- *Debridment and lavage*—the physical flow of saliva, augmented by muscular activity of lips and tongue, effectively removes a large number of potentially harmful bacteria from the teeth and mucosal surface.
- *Anti-carcinogenic activity*—mucins limit the penetration of variety of potential irritants and toxins in foods, beverages as well as potentially hazardous agents from tobacco smoke and other sources.

- *Soft tissue repair*—presence of nerve growth factor and epidermal growth factor in submandibular saliva accelerates wound healing.
- *Maintenance of tooth integrity*—after the eruption the crown, the tooth is fully formed morphologically, but is crystallo-graphically incomplete. Interaction via diffusion of ions such as calcium, phosphorus, magnesium, fluoride as well as other trace components into the surface of enamel, increases the surface hardness, decreases permeability and increases the resistance to caries. Acquired pellicle, which covers the tooth surface after it begins to function in oral cavity, is made up of salivary proteins and lipids.
- *Maintenance of pH*—it helps in maintenance of neutral pH in oral cavity and in esophagus. The salivary bicarbonates are responsible for maintenance of pH. Saliva also neutralizes the acids produced in bacterial plaque because of bacterial metabolism of carbohydrates.
- *Excretory functions*—many drugs as well as alcohol are excreted into saliva which could theoretically serve as a route of elimination.
- *Water balance*—salivary glands are a part of the control system for maintaining an appropriate level of hydration. Thirst and the need for fluid intake are usually originated by a dry mouth, which activates receptors in the oral cavity.
- *Hormonal function*—polypeptide hormones known as epidermal growth factor, is identical with human urogastrone which is found in high concentration in urine. It is also found in submandibular and parotid saliva.
- *Bimanual palpation*—palpation should be performed in the lateral surface of the mandible and on the soft tissues inferior and medial to the angle. Bimanual palpation with the patient's mouth closed: with the masseter muscle relaxed, this method can be readily performed from the side or behind. Insertion of the index finger along the teeth to the most posterior location in the cheek with application of lateral pressure against the examining thumb on the face, this palpation can be performed.
- *Examination of Stensen's duct*—Stensen's duct orifice should be identified adjacent to the upper molar teeth as a small fold or soft tissue flap in the buccal surface. The mucosa in the area should be dried with cotton sponge and the duct orifice observed for secretion while the gland is milked by applying firm pressure. The pressure is applied first in the posterior aspect, beneath the auricle and moving the palpating finger anteriorly and inferiorly, along the course of Stensen's duct. Clear, colorless secretion that is sufficiently fluid to flow rapidly should be observed emanating from the duct orifice.

Submandibular Glands

- *Location of swelling*—submandibular salivary gland enlargement is characterized by medial and inferior extension, the later resulting in discontinuity if the tissue contours at the inferior border of mandible.
- *External palpation*—external palpation should start with the finger extending towards the midline and the thumb on the body of the mandible. Pressure is exerted, both, superiorly and laterally and the finger is gradually moved beneath the inferior border of the mandible.
- *Palpation*—the patient should be advised to relax the tongue during palpation. Enlarged lymph nodes, except those involved with malignancy, will invariably move laterally with the examining finger, while the submandibular salivary gland will remain stationary.
- *Bimanual palpation*—after this, bimanual palpation should be performed; the examiner placing the 2nd finger of one hand into the floor of the mouth beneath the tongue, the patient resting his teeth on the examiners fingers, while the fingers of the other hand are placed as previously described, that is on the skin beneath and medial to the body of the mandible. While pressure is exerted inferiorly intraorally by the finger, the other hand moves superiorly and laterally so that all organs come between the examiner's two hands.

Sublingual Salivary Glands

- *Location*—these are located in the floor of the mouth in the region of the middle third of the tongue, closely applied to its medial musculature attachment. The ductile pattern is extremely variable, frequently communicating with the mouth through a series of small orifice, rather than by means of small collecting ducts.

Examination of Salivary Glands

Minor Salivary Glands

- *Technique*—the minor salivary glands can be examined by simply drying the lower lip mucosa with cotton sponge, after eversion using thumb and index finger. Careful observation for the appearance of small globules of fluid emanating from minor gland duct orifice should be done. In situations where atrophy or significant reduction in salivary secretion has occurred, such as in Sjögren's syndrome, the duct orifices will be marked by small red spot and secretion will not be observed.

Major Salivary Glands

Parotid Glands

- *Location of swelling*—swelling of the parotid gland is usually associated with lateral extension of the lobe of the ear and difficulty in opening the jaw widely.

Diagnostic Tests of the Salivary Glands

- *Sialography*—it is defined as a method of studying the salivary gland and the alveoli of the parotid and submandibular salivary gland radiographically. It is done by injecting radiopaque contrast medium or a retrograde injection of a radiopaque material into the duct system of a salivary gland and the study of its distribution by roentgenogram.
- *Salivary gland scanning (scintigraphy)*—it is used for studying the glandular parenchyma. The salivary gland tissues take up compounds of periodic group VII elements such as iodine, bromine and technetium. It provides indication of salivary gland functions and allows bilateral comparisons and images of all four major salivary glands at the same time.
- *Ultrasonography*—it involves the transmission of energy into the salivary tissues, receiving of the energy after it has been reflected by the tissues and recording it so that it can be presented for interpretation. It is also useful in identification of radiolucent stone. Different echo signals are obtained from different tumors.
- *Computerized tomography*—it demonstrates small differences in soft tissues X-ray examination and distinction between gland and the adjacent soft tissues is greatly improved. It is usually done in cases of discrete swelling, both intrinsic and extrinsic to the salivary gland.
- *Arteriography*—it will define the vasculature of the tumor but also delineates the origin of vascular supply.
- *Biopsy*—it has been the most significant advancement in diagnosis and appropriate treatment of major salivary gland tumors.
- *Flow rate studies*—comparative study of flow rate from major salivary glands is done over a time period. It provides information about salivary gland functions.
- *Magnetic resonance imaging*—it is useful in discrete swelling of salivary glands and provides excellent soft tissue details. It readily enables differentiation between the normal and abnormal.

Classification

Developmental disorders

- Aberrancy
- Aplasia and hypoplasia
- Hyperplasia
- Atresia
- Accessory ducts
- Diverticuli
- Congenital fistula

Functional disorders

- Sialorrhea
- Xerostomia

Obstructive disorders

- Sialolithiasis
- Mucus plug
- Stricture and stenosis
 - Foreign bodies
- Extra-ductal causes

Cyst

- Mucocele
- Ranula

Asymptomatic enlargement

- Sialosis
- Allergic
- Associated with malnutrition and alcoholism

Infection

- Viral infection
- Bacterial infection
- Mycotic infection

Autoimmune disorders

- Sjögren's syndrome
- Mikulicz's disease
- Uveoparotid fever
- Recurrent non-specific parotitis

Developmental Disorders of Salivary Gland

Aberrancy

It is defined as the situation in which the salivary gland tissue develops at a site where it is not normally found. It is also called as *ectopic salivary gland*.

Ectopic salivary tissue can develop anywhere within the territory of the first and second branchial arches, in the lateral neck, pharynx or middle ear.

Clinical Features

- *Site*—true aberrant salivary glands are most frequently reported in the cervical region, near the parotid gland or body of the mandible. The salivary gland tissue in the mandible is found posterior to the first molar and often has a small communication with a major salivary gland.
- *Developmental lingual salivary gland depression*—the aberrancy of the salivary gland tissue represents only an extreme example of the condition known as the 'developmental lingual mandibular salivary gland depression'. It is the developmental inclusion of the

glandular tissue within or more commonly, adjacent to the lingual surface of the body of the mandible, in a deep well circumscribed depression. It was first described by Stafne in 1942 and hence referred to as 'Stafne's cyst'.

- *Salivary tissue in neck*—salivary tissue is regularly found in lymph nodes within the neck and can be mistaken for metastatic disease, if found in a neck dissection specimen.
- *Gingival salivary gland choristoma*—ectopic salivary gland tissue has been reported to occur in the gingiva, where it may be described as 'gingival salivary gland choristoma'.
- *Clinical significance*—they may become site for development of a retention cyst or neoplasm.

Aplasia and Hypoplasia

Aplasia or agenesis is the congenital absence of the salivary gland. It was first described by Gruber in 1885. Aplasia may occur in association with other developmental abnormalities such as atresia of lacrimal puncta and congenital malformation of temporomandibular component.

Causes

- *Ectodermal origin*—Macdonald suggested ectodermal origin for this anomaly.

Clinical Features

- *Sites*—any one of the glands or group of glands is missing, either unilaterally or bilaterally. Hypoplasia of salivary gland is rare but hypoplasia of parotid gland has been reported to be present with Melkersson-Rosenthal syndrome.
- *Symptoms*—patient complains of xerostomia, which may be so severe as to necessitate the constant sipping of water throughout the day and particularly, during meal times.
- *Significance*—the lack of saliva results in rampant dental caries and early loss of deciduous and permanent teeth.
- *Appearance of oral mucosa*—the oral mucosa appears dry, smooth, or sometimes pebbly and shows a tendency for accumulation of debris.
- *Signs*—patients exhibit characteristic cracking of lips and fissuring of the corners of mouth.

Radiological Features

- *CT features*—it is sometimes observed that unilateral gland is missing (Fig. 26-5) or is very small compared to the contralateral side with congenital or posterior reasons. As they are mostly asymptomatic, the condition is mostly diagnosed by chance.

Fig. 26-5: Hypoplasia of the unilateral parotid gland (Plain CT). Size of the left parotid gland (yellow arrow) is remarkably smaller compared with normal size of the right parotid gland (red arrow) (Courtesy M Shimizu).

Diagnosis

- *Clinical diagnosis*—decreased production of saliva without any other visible clinical anomalies this disease should be suspected.
- *Radiological diagnosis*—Computed tomography will be able to diagnose this lesion.

Management

- *Maintenance of oral hygiene*—institution of scrupulous oral hygiene in an attempt to decrease dental caries and preserve the teeth as long as possible.

Hyperplasia of Salivary Gland

Hyperplasia is the increase in the size of salivary gland.

Causes

- *Hormonal disorders*—endocrine disorders and menopause.
- *Metabolic disorders*—gout, diabetes mellitus.
- *Autoimmune*—Sjögren's syndrome, Waldenström macroglobulinemia.
- *Syndrome*—aglossia-adactylia syndrome, Heerfordt's syndrome and Felt's syndrome.
- *Miscellaneous*—hepatic disease, starvation, alcoholism, inflammation, benign lympho-epithelial lesion, adiposity, hyperthermia, oligomenorrhea and certain drugs.

Clinical Features

- *Prevalence*—it is more common in minor salivary glands of the palate.

- *Size and site*—palatal gland hyperplasia appears as small localized swelling of varying size, measuring from several millimeters to 1 cm, usually on the hard palate or at junction of hard and soft palate.
- *Surface*—the lesion has an intact surface and is firm, sessile and normal in color.
- *Symptoms*—it is usually asymptomatic.

Radiological Features

- *CT features*—Computed tomography will diagnose this condition.

Diagnosis

- *Clinical diagnosis*—it is not specific.
- *Radiological features*—computed tomography will diagnose this condition.

Management

- *Excision for microscopic examination*—as it cannot be differentiated from minor salivary gland tumors, it becomes essential to excise it for microscopic examination.

Atresia

It is the congenital occlusion or absence of one or two major salivary gland ducts. Usually the submandibular duct in the floor of the mouth fails to cannulate during embryological development. The newborn infant presents, within 2 or 3 days of life, with submandibular swelling on the affected side due to the presence of a retention cyst. It may produce a relatively severe xerostomia.

Accessory Duct

An accessory parotid lobe is the most common developmental anomaly. It occurs in as many as 20% of subjects. Its position is constant, arising from the horizontal component of the parotid duct as it crosses the masseter muscle. Its importance lies in the fact that any of the diseases that can affect the salivary glands, may involve the accessory lobe and lead to diagnostic confusion, as the possibility is not considered. This is because the symptoms and signs are not within the normal anatomical territory of the parotid. Presence of additional duct in some salivary glands has been reported.

Diverticuli

They are small pouches or out pocketing of the ductal system of one of the major salivary glands. Their presence leads to recurrent episodes of acute parotitis.

Congenital Fistula

Patients with branchial cleft anomalies usually present with unilateral, painless swelling in the region of parotid. Rarely, they are bilateral. They form sinus tracts either in the crease behind the pinna or in front of tragus. They discharge saliva intermittently. Abscess formation, due to secondary infection, may occur. Complete surgical excision of the sinus tract is essential. The dissection is often very extensive and full dissection of facial nerve may be required.

Developmental Salivary Gland Defect

It is also called as '*static bone cavity or cyst*', '*Stafne's cyst or defect*', '*lingual mandibular bone cavity*', '*lingual cortical mandibular defect*', and '*latent bone cyst*'. It is the developmental inclusion of glandular tissue within or more commonly, adjacent to the lingual surface of the body of mandible. It was recognized by Stafne in 1942. Mandible develops around the lobe during development. As it remains stable in size, it is called as '*static bone cyst*'.

Clinical Features

- *Incidence and sex*—it is rare. Males are affected more commonly than females.
- *Site*—it is located in the posterior body of the mandible.
- *Sublingual gland bony defect*—in some cases cortical defect can also occur in anterior region. These defects are related to sublingual gland.
- *Symptoms*—it is asymptomatic and only diagnosed on radiographical examination.
- *Sign*—sometime a notch or depression can be palpable on clinical examination in the posterior area.

Radiographic Features

- *Site*—it is found below the mandibular canal and above the inferior border of mandible, just anterior to the angle of jaw and below and just posterior to third or second molar (**Fig. 26-6**).
- *Size and shape*—round or ovoid radiolucency that will vary in size from 1 to 3 cm in diameter. It is occasionally bilateral.
- *Borders*—it is well defined by dense radiopaque border that is the result of the rays passing tangentially through the relatively thick wall of depression.
- *Sublingual bony defect*—in some instances, round or ovoid radiolucency may occur in the anterior segment of the mandible, generally appearing as a rather poorly circumscribed lesion, somewhere between the first premolar and central incisor area. This may be caused by impingement of sublingual gland.

Fig. 26-6: Stafne's bone cyst presented as radiolucency below the mandibular canal and surrounded by well corticated border (Courtesy Dr Tapasya Karamore).

Diagnosis

- *Clinical diagnosis*—it is not possible or suspect this disease clinically.
- *Radiological diagnosis*—round radiolucency located below the mandibular canal in molar area will diagnose this condition.

Differential Diagnosis

- *Radicular*—it is associated with carious tooth and radiolucency is attached to the root of teeth.
- *Residual*—pre-extraction radiograph shows tooth with evidence of deep caries.

Management

No treatment is necessary as the patient is asymptomatic.

Functional Disorders of Salivary Gland

Sialorrhea (Ptyalism)

An increased salivary secretion is termed as 'sialorrhea' or 'ptyalism'.

Mechanisms

The secretory innervations of the salivary glands are primarily under the control of the parasympathetic nervous system. Stimulation of the parasympathetic system causes profuse secretion of watery saliva. Some persons are unable to swallow their saliva fast enough to prevent drooling.

Etiology

- *Drugs*—certain drugs have the ability to stimulate salivary flow. Such drugs are known as 'sialogogues'. Increased salivation due to drugs can result from a variety of its pharmacologic effects. Besides acting on the parasympathetic and sympathetic receptors, drug action can lead to sialorrhea by direct CNS stimulation or as a result of nasal and oropharyngeal irritation, which leads to afferent stimulation of salivary nuclei. Drug which can cause sialorrhea are lithium and cholinergic agonists.
- *Local factors*—it can be the result of, different types of stomatitis, ANUG, erythema multiforme.
- *Systemic disease*—paralysis, alcoholic neuritis, Parkinson's disease, epilepsy, Down's syndrome, undetermined neuromuscular disorders or following a head injury or stroke.
- *Protective buffering system*—episodic hypersecretion of saliva or 'water brash' may occur as protective buffering system to neutralize stomach acid in individual with gastroesophageal reflux disease.
- *Miscellaneous*—psychic factor, metal poisoning and facial paralysis.

Clinical Features

- *Drooling*—the salivary flow is more in infancy and childhood, but the drooling observed in infants is related to inadequate swallowing rather than excessive production. Drooling or sialorrhea can be a devastating problem for the affected child or adult.
- *Symptoms*—the problem may range from mild embarrassment and discomfort to emotional and physical impairment. The involved person may require numerous clothings and/or bib changes per day.
- *Signs*—he or she may develop cheek scarring, lip chapping or infection from constant exposure to saliva. The soiling of clothes, carpets, furniture, books and people, often results in social rejection, employment difficulties and stigmatization.

Management

- *Treatment in children*—no treatment is recommended in children less than four years of age with only mild or moderate amount of drooling, which may improve spontaneously.
- *Oral motor training*—oral motor training, intended to improve motor skills, is the key non-surgical management modality and all patients (if appropriate) should have a minimum of six months of this type of therapy format, before any surgical management is considered.

- *Biofeedback*—biofeedback utilizes conditioning techniques to train the patients to swallow more frequently. It has been utilized in aware patients with only a modest drooling problem and who have very motivated parents.
- *Removal of local factors*—situational factors that may contribute to drooling should be eliminated if possible, i.e. dental disease, nasal airway obstruction, poor seating and inappropriate medications.
- *Atropine*—the anti-cholinergic drug, atropine sulfate, has been shown to reduce the amount of resting secretion, intraoral accumulation and pharyngeal-laryngeal pooling of saliva in more than 50% of patients.
 - *Mechanism of action*—the drug is a competitive antagonist of muscarinic actions of acetylcholine. It does not prevent the release of acetylcholine, but antagonizes the effect of this neurotransmitter on the effector cells. This action results in drying of the mouth through reduction of salivary gland secretions. Atropine-induced inhibition of salivation occurs within 30 minutes to one hour. Inhibition peaks within two hours after oral administration, but can persist for up to four hours.
 - *Dose*—the usual oral dose for adults is 0.4 mg, every 4 to 6 hours. In children, the suggested dose is 0.01 mg/kg, but generally not exceeding 0.4 mg, every 4 to 6 hours.
 - *Contraindication*—due to potential side effects, atropine sulfate is contraindicated in patients with asthma, glaucoma or synechia (adhesions) between the iris and lens of the eye.
- *Other drugs*—other drugs which are used as anticholinergics are scopolamine (0.4-0.6 mg), methantheline (50-100 mg) and propantheline (15-30 mg).
- *Surgery*—surgery is a primary recommendation in individuals with a cognitive delay and profuse drooling and secondarily in those that have failed to non-surgical therapy for a minimum of six months.
 - *Relocation of duct*—relocation of submandibular and parotid duct posteriorly to the tonsillar fossa. This will reduce salivary flow and drooling.
 - *Bilateral tympanic neurectomy*—sectioning of chorda tympani destroys parasympathetic innervations to the glands.

Xerostomia

It is the subjective clinical condition of less than normal amount of saliva. It is dryness of mouth, which is a clinical manifestation of salivary gland dysfunction.

Etiology

- *Radiation induced*—ionizing radiation to head and neck region for the treatment of cancer results in pronounced changes in the salivary glands located within the primary beam. The degree of damage caused by the radiotherapy is related to dose-time-volume factor. Damage to the acinar cells has been noted with a single 100 rads dose of X-rays. Radiation sensitivity decreases in following order: the parotid gland, submandibular, sublingual to minor glands. Serous acinar cells appear to be more sensitive to radiation, than the mucus cells. As the dose is increased, disorganization and destruction of the acinar cells occur, resulting in their replacement by fibrous or faulty tissues. Both, the stimulated and unstimulated salivary flow rate decreases dramatically with increasing radiotherapy.
- *Pharmacologically induced xerostomia*—there are about 500 drugs which can cause xerostomia. The classes of drugs which cause xerostomia include anticonvulsants, antiemetics, antihistaminics, anti-hypertensives and antispasmodics. The mode of action for decreased salivary flow is generally related to the para-sympathetic activity, usually an antimuscarinic effect. Other actions that can decrease salivation are generally more miscellaneous and include vasoconstriction of salivary glands, changes in fluid and electrolyte balance and changes in acinar or ductal function.
- *Local factors*—local factors like decreased mastication, smoking and mouth breathing can also lead to xerostomia.
- *Developmental*—developmental abnormalities of salivary glands, tumors, autoimmune states and certain diseases which affect afferent or efferent portions of neural transmission reflex are some of the other causes of xerostomia.
- *Systemic alterations resulting in xerostomia*
 - *Nutritional*—certain deficiency states like pernicious anemia, iron deficiency anemia and deficiency of vitamin A and hormones can cause xerostomia.
 - *Fluid loss*—fluid loss associated with hemorrhage, sweating, diarrhea, vomiting.
 - *Diabetes mellitus*—it is associated with xerostomia.
 - *Sjögren syndrome*—xerostomia is also common in Sjögren syndrome.
 - *Other disease*—systemic diseases, which are accompanied by high temperature and dehydration, usually result in diminished salivation. Xerostomia may also be found in HIV infection, sarcoidosis, and graft versus host resistance.

Clinical Features

- *Effect of xerostomia on oral functions*—patient may notice increased thirst, increased uptake of fluid especially while eating. There is also frequent use of means like chewing gums and consumption of sour candy. Patient

also gets difficulty in swallowing, speech and eating dry food. There is also burning and tingling sensations in the mouth. There is also complaint of frequent oral infections, intolerance to dental appliances and abnormal taste in the mouth.

- *Salivary gland enlargement*—painful salivary gland enlargement is also present.
- *Effect of xerostomia on normal functions*—many times, xerostomia is accompanied by hypofunction of other secretory glands. Blurred vision and ocular dryness. Itching, burning and sandy sensation in eye. There is also dryness of pharynx and skin. Itching and burning sensation of vagina.
- *Clinical signs of xerostomia*—dryness of lining oral mucosa. Oral mucosa appears thin, pale and feels dry. Tongue blade may adhere to soft tissues. Tongue may manifest deficiency by atrophy of the papillae, inflammation, fissuring, cracking and denudation. There is also increased incidence of dental caries.
- *Candidiasis*—pseudo membranous and hyperplastic form of candidiasis occurs. The reason for occurrence candidiasis is absence of normal cleansing and antimicrobial activity of the saliva.
- *Residual saliva*—residual saliva which remains is foamy, thick and ropey.

Management

Stimulation of salivary production

- *Local stimulation*—chewing of gums, mints, paraffin and citric acid containing lozenges and rinses. Disadvantages of it are:
 - Effects are short lived.
 - Frequent application can be inconvenient.
 - Citric acid may irritate oral mucosa.
 - Continuous use may contribute to demineralization.
- *Systemic stimulation*
 - *Bromhexine*—it is a mucolytic and mucokinetic agent, capable of inducing thin copious bronchial secretions. Dose—adults (8 mg TDS), children 1-5 years (4 mg BD) and children 5-10 years (4 mg TDS).
 - *Anethole trithione (ANTT)*—it is a directly acting cholinergic agonist which acts by neurostimulation. Dose 1 to 2 tabs (25 mg) TDS.
 - *Pilocarpine*—pilocarpine is a cholinergic parasympathomimetic agent with a broad range of pharmacologic effects. It increases the secretion by exocrine glands and can affect the sweat, salivary, lacrimal, gastric, pancreatic, intestinal glands and mucosal cells of the respiratory tract. The usual dose is 5 mg, TDS. It produces short duration of (3 hours) increased salivary flow, without the accompanying side effects. It should not be used in patients suffering from asthma.

Symptomatic treatment

- *Salivary substitute*—there are number of salivary substitute available for the treatment of xerostomia. Most commonly contain carboxymethylcellulose or hydroxyethylcellulose as lubricants and variety of artificial sweeteners, preservative and chloride or fluoride salts. Disadvantages are:
 - Their regular use is inconvenient to the patient.
 - Most of them are more viscous than the natural saliva.
 - They are expensive.
 - They fail to provide antimicrobial and other protective functions of natural saliva.
- *Composition of artificial saliva*
 - Carboxymethylcellulose—10 gm/l.
 - Sorbitol—30 gm/l.
 - Potassium chloride—1.2 gm/l.
 - Sodium chloride—0.843 gm/l.
 - Magnesium chloride—0.051 gm/l.
 - Calcium chloride—0.146 gm/l.
 - Dipotassium hydrogen phosphate—0.342 gm/l.
- *Oral hygiene product*—patient should use oral hygiene product which include lactoperoxidase, lysozyme, and lactoferrin.
- *Discontinuous of drug*—drug which is causing xerostomia should be discontinued.

Suggestions to the patient having xerostomia

- *Sweet and tart food*—try very sweet or tart foods and beverages such as lemonade; these foods may help to produce more saliva. (Do not try this in sensitive teeth or sore throat.)
- *Sucking of sugar free candy*—suck on sugar-free hard candy (avoiding those with citric acid), popsicles or chew sugar-free gum. These can help produce more saliva.
- *Sucking ice cubes*—try sucking ice cubes or ice lollies. Home-made lollies can be easily made by freezing fresh juice in ice-cube trays or in special lolly containers with sticks, which can be bought from many kitchenware shops.
- *Don't take following thing*—avoid chewable vitamin C and acidic, sugared lozenges. Avoid dry foods such as cookies, toast and crackers, or soften them with liquids before eating. Avoid chocolates, peanut butter and pastry: they stick to the roof of mouth. Avoid over salty foods.
- *Soft and liquid food*—use soft and liquid foods, which may be easier to swallow.
- *Drink frequently*—have a sip of water every few minutes to help in swallowing and talking more easily. Carry a small water bottle for frequent sips during the day.

Obstructive Disorders

Sialolithiasis

It is the formation of calcific concretions within the parenchyma or ductal system of the major or minor salivary glands. It is also called as 'salivary gland stone' or 'salivary gland calculus'. These are stones within major and minor salivary glands. These are the most common calcifications found in soft tissues of oro-orbital region.

Composition

- *Calculus*—the calculus consists of laminated layers of organic material, covered with concentric shells of calcified material.
- *Crystalline structure*—the crystalline structure is chiefly hydroxyapatite and contains octacalcium phosphate.
- *Chemical composition*—the chemical composition is principally calcium phosphate and carbon with traces of magnesium, potassium, chloride and ammonium.

Etiopathogenesis

- *Neurohumoral mechanism*—a neurohumoral condition, leading to salivary stagnation, results in a nidus and matrix formation.
- *Metabolic mechanism*—in the presence of coexisting inflammation, a metabolic mechanism favors precipitation of salivary salts into the matrix.

Prevalence

Submandibular (83%) calculi are more commonly seen than the parotid (10%) or sublingual (7%) calculi, due to following factors.

- *Anatomic factors*
 - The length and irregular course of Wharton's duct.
 - The submandibular gland and ductal system lies in a dependent position.
 - The greater size and position of the orifice.
 - The orifice is much smaller than duct lumen.
- *Physiochemical factors*
 - High mucin content of saliva.
 - Great degree of alkalinity with high percentage of organic matter.
 - Greater concentration of calcium and phosphate salts.
 - Low content of carbon dioxide.
 - Richness in phosphatase enzyme.

Types

- *Ductal sialoliths*—it is located in the duct of gland.
- *Glandular sialoliths*.

Clinical Features

- *Age and sex*—they are usually encountered in middle aged patients with slight predilection for occurrence in men.
- *Symptoms*—the symptoms of sialolithiasis vary but intra-glandular stones seem to cause less severe symptoms than the extraglandular or intraductal types. On occasions, there may be complete absence of subjective symptoms.
 - *Pain*—many patients complain of moderately severe pain. The occlusion of the duct prevents the free flow of saliva and this stagnation or accumulation of saliva, when under pressure, produces pain.
 - *Swelling*—patient also complains of intermittent transient swelling during meals, which resolves after meals. As the calculus itself rarely blocks a duct completely, the swelling subsides as salivary demand diminishes and as saliva seeps past the partial obstruction.
 - *Systemic symptoms*—if no treatment is instituted, it appears as a pronounced exacerbation characterized by an acute suppurative process with attendant systemic manifestations such as fever and malaise.
- *Signs*
 - *Pus*—pus may exude from the duct orifice.
 - *Surrounding tissue*—the soft tissues surrounding the duct show a severe inflammatory reaction. It appears as swelling, redness and tenderness.
 - *Palpation*—stones in the more peripheral portion of the duct may often be palpated, if they are of sufficient size.
 - *Ulceration*—sometimes, the overlying mucosa may ulcerate over the stone allowing the calculus extend into the oral floor.
 - *Absence of saliva*—no saliva is seen to be coming out through the duct orifice.
- *Swab test*—if stone is present in one duct only then saliva will not come out from that duct. It can be tested by placing two dry swabs one on each orifice and some lemon juice is dropped on the dorsum of the tongue. A minute later patient is asked to move the tongue up. The swab on the orifice of the duct where the stone is impacted will remain dry, whereas the other swab will be wet.
- *Size*—it usually occurs as a solitary concretion varying in size from a few millimeters up to several centimeters.
- *Stones in minor salivary glands*—sialolithiasis of minor salivary gland is a rare occurrence. The most common site is buccal mucosa either near the commissure or in proximity to the mandibular mucobuccal fold. It is more common after the age of 39 years. The lesions appear as firm, freely movable masses, deeply situated into the mucosal surface.

Radiographic Features

- *View taken*—projection for submandibular duct stone is standard mandibular occlusal view and for parotid gland, periapical view in the buccal vestibule. Reduce the exposure to avoid burnout of sialoliths.
- *Sialography*—sialography is indicated when sialoliths are radiolucent. There is ductal dilatation caused by associated sialodochitis. The film usually shows contrast medium present behind the stone.
- *Site*—there is white or gray opacity situated somewhere in the region of the glandular apparatus. It may be solitary or multiple.
- *Radiodensity*—they are almost radiopaque, so that even very small ones are visible in well prepared radiograph (Fig. 26-7).

Fig. 26-7: Well defined radiopacity seen at the angle of mandible due to salivary stone (Courtesy Enzo Rovigutti)

- *Shape*—it is usually oval shaped and is cylindrical with multiple layers of calcification.
- *Borders*—smooth borders with even radiodensity.
- *Size*—the size varies from little more than a pinhead up to a length of an inch (Fig. 26-8) or more, with a girth of about 5 mm.
- *CT*—it will show dense radiopaque area in contrast study (Fig. 26-9).

Diagnosis

- *Palpation*—palpation is an indispensable tool in the diagnosis of sialoliths. Palpation of the suspected gland frequently reveals it to be larger or firmer than the normal gland of the opposite side. Digital manipulation will produce a flow of saliva through the duct orifice and will allow visual inspection of the salivary fluid. During examination, the soft tissues overlying the duct should be manually stretched. Often, the physical distortion caused by the presence of calculus will become apparent. In addition yellowish color of the calcific deposits may

Fig. 26-8: Small size salivary stone present as radiopacity in ramus of mandible (Courtesy Enzo Rovigutti).

Fig. 26-9: Well defined radiopaque area seen in submandibular gland (Courtesy Dr Iswar).

be seen through the distended and thinned mucus membrane.

- *Metallic duct probe*—a metallic duct probe can also be valuable. Careful probing of the duct with a metallic probe will indicate the existence as well as the location of calculus.
- *Radiographic examination*—radiographic examination usually reveals the presence of calcific deposits.
- *Sialography*—sialography is an invaluable aid in isolating the sialoliths which had not been identified on the standard intraoral and extraoral radiography.

Differential Diagnosis

- *Gas bubble*—it should not be confused with gas bubbles introduced during sialography. Gas bubbles are more easily removed and are more circular than sialoliths.
- *Hyoid bone*—bilateral on panoramic radiography.
- *Myositis ossificans*—restriction of mandibular movements.
- *Phleboliths*—no sialadenitis present. They are more or less rounded and contain laminations or central dark area.
- *Calcific submandibular lymph nodes*—if painful swelling accompanies the calcified mass, it is usually sialolith.
- *Chondrodystrophia calcificans congenita*—it is sometimes associated with calcification in the neck, which can resemble the submaxillary calculi in the radiographs.

Management

- *Manual manipulation*—in case of small stone, gentle massage of the gland should be done. It will help to move the stone toward the duct orifice. Sialogogues, moist heat and increased fluid intake will also promote the passage of stone.
- *Stone in the submandibular duct*—if the stone is palpated near the orifice of the duct it can be removed by an incision made directly over it through the mucus membrane of the mouth.
- *Stone in the submandibular gland*—in this case, excision of gland is advised.
- *Antibiotics*—if acute infection is present, then antibiotics should be given.
- *Salivary gland endoscopy*—this is newer method which is useful in removal of sialoliths.
- *Lithotripsy*—this is fragmentation of stone in the gland. Nowadays, extracorporeal shock wave lithotripsy has been successful in many patients.

Mucus Plugs

These are incompletely mineralized sialoliths. Clinical symptoms and signs are same as that of stones. The diagnosis of mucus plug is based upon clinical history, radiography and sialograms. If sialograms confirm the intraductal obstructive disease secondary to non-mineralized intraductal object, the diagnosis of mucus plug can be made.

Strictures and Stenosis

These are the rare conditions occurring in the salivary gland area.

Etiology

- *Irritation*—irritation from prosthetic appliances, maloccluded or malpositioned teeth.

- *Acute trauma*—acute trauma with resultant edema and/or scarring.
- *Tumor*—intraductal tumor formation.

Types

- *Papillary obstruction*—it may be either acute ulcerative obstruction or chronic fibrotic stenosis. Acute ulcerative obstruction is usually caused by acute trauma to the papilla and is treated conservatively with saline rinses and salivary gland massage. The ulcer generally heals without scarring and the symptoms will subside in such cases. In chronic fibrotic papillary obstruction irritations to papilla has been recurrent and scarring exists.
- *Duct obstruction*—it may be due to a variety of factors. In cases of ductal obstruction secondary to acute trauma treatment is directed towards providing the duct patency until the edema is resolved. When the ductal obstruction occurs secondary to irritation or scar contracture, sialograms are helpful in localizing the status of gland. If the gland is healthy, progressive and frequent dilatation of involved duct with lacrimal probes is generally successful in relieving the symptoms and signs. If this does not prove beneficial, ductoplasty is indicated.

Foreign Bodies

Rarely, foreign bodies become lodged within Wharton's duct and less commonly in Stensen's duct. Toothbrush bristles, toothpicks, spikes of wheat, fish bone, portions of fingernail have been reported within the salivary gland duct and act as causes of obstructive and/or inflammatory disease of the salivary gland.

Extraductal Causes

Muscle pressure, tumors, enlarged lymph nodes and denture flanges associated with the primary salivary duct can cause obstructive signs and symptoms.

Parotid Fistula

It may arise from parotid gland or duct. It may be internal, when it opens inside the mouth and external, when it opens to the exterior.

Causes

- *Traumatic*—penetrating injury particularly by glass splinters.
- *Parotid abscess*—rupture of parotid abscess.
- *Inadvertent incision*—inadvertent incision while draining of parotid abscess.
- *Complication*—complication of superficial parotidectomy.

Clinical Features

- *Symptoms*—the main complaint is opening in the cheek with discharge.
- *Signs*—discharge come out only during meals.
- *Adjacent skin*—there may be excoriation of the neighborhood skin.

Sialograms

- It will give an indication whether the fistula is in relation to the main duct, ductile or to the gland.

Diagnosis

- *Clinical diagnosis*—discharged from Stensen's duct after trauma or surgery.
- *Radiological diagnosis*—it will exactly diagnose the parotid fistula.

Management

- *Reconstruction of the duct*—it is done by surgical approach.

Cysts of Salivary Gland

Mucocele

It is a term used to describe the swelling caused by pooling of saliva at the site of injured minor salivary gland. It is also called as 'mucus extravasation phenomenon, mucus escape reaction'. It is not true cyst it lacks an epithelial lining.

Etiopathogenesis

- *Trauma*—it is caused by laceration of a minor salivary gland duct by trauma resulting in extravasation of mucus into the connective tissue. There is accumulation of mucus in the connective tissue and with the continuous pooling of saliva a clearly demarcated cavity develops which has no epithelial lining.

Clinical Features

- *Age and sex*—mucus extravasation cysts occur in younger patients. The reason for occurrence in young people as they are more prone to trauma that induce mucin spillage. It is equal in both sexes.
- *Site*—they are very common and occur most frequently on the inner aspect of lower lip (**Fig. 26-10**); but may also occur on the palate, cheek, tongue and floor of mouth. The lesion may lie fairly deep in the tissues or may be exceptionally superficial.
- *Symptoms*—patient may complain of painless swelling which is frequently recurrent. The swelling may suddenly develop at meal time and may drain simultaneously at intervals.

Fig. 26-10: Mucus extravasation cyst seen on lower lip (Courtesy Dr Parate).

- *Size*—the mucocele may be only 1-2 mm in diameter, but is usually larger; majority of them being between 5 and 10 mm in diameter.
- *Appearance*—superficial cyst appears as bluish mass, as the thin overlying mucosa permits the pool of mucus fluid to absorb most of the visible wavelength of light (**Fig. 26-11**). If inflamed, it is fluctuant, soft, nodular and dome shaped elevation. Deeper lesions have the color of normal mucosa and are firmer.

Fig. 26-11: Bluish color of mucocele seen on lower lip.

- *Shape*—the swelling is round or oval or dome shaped (**Fig. 26-12**).
- *Consistency*—it is either soft or hard depending upon the tension in the fluid. It cannot be emptied by digital pressure.
- *Aspiration*—on aspiration, it yields sticky viscous clear fluid.
- *Superficial mucocele*—it is present as single or multiple tense vesicles that measures 1 to 4 mm in diameter. The lesion burst leaving shallow painful ulcer that heals

Fig. 26-12: Dome-shaped swelling of mucocele (Courtesy Dr Parate).

within a few days. It is seen on soft palate and posterior buccal mucosa.

- **Recurrence**—patient may give history of recurrent swelling which ruptures and reappears again after some time.

Diagnosis

- **Clinical diagnosis**—dome shaped soft swelling on lower lip which is lateral to midline is typical features of mucocele.
- **Laboratory diagnosis**—in biopsy, it shows vacuolated macrophages which are sometimes called as ‘muciphage’.

Differential Diagnosis

- **Vascular lesion and superficial non-keratin cyst**—aspiration should be done.
- **Early Mucoepidermoid tumor and adenocarcinoma**—induration is present.

Management

- **Surgical excision**—complete excision of the mucocele should be done under local anesthesia. To avoid recurrence, adjacent minor salivary gland should also be removed which are feeding the lesion.
- **Cryosurgery**—surgery with cryoprobe is also helpful in managing the mucocele.

Ranula

It is derived from Latin word ‘*Rana tigrina*’, i.e. frog belly. The term ranula is used for the mucoceles occurring in the floor of the mouth, in association with ducts of submandibular or sublingual glands.

Types

- **Superficial**—the superficial variety may develop as a retention or extravasation phenomenon associated with trauma to one or more of the numerous excretory ducts of the sublingual salivary gland.
- **Plunging or cervical**—it ramifies deeply into the neck.

Clinical Features

- **Age and sex**—it is usually seen in children and young adults with no sex predilection.
- **Site**—the typical position is on the floor of the mouth (Fig. 26-13), below the tongue and on the side of frenum. They are usually unilateral.

Fig. 26-13: Unilateral swelling seen on left side in floor of mouth (Courtesy Dr Datarkar)

- **Symptoms**—it develops as slowly enlarging painless mass on one side of the floor of mouth. When the swelling suddenly grows, it may be painful. Big ranula may cause difficulty in speech or eating.
- **Appearance**—they produce blue shaped swelling (Fig. 26-14) like a frog’s belly, hence it was given the term ‘ranula’ (‘ranula’ in Greek mean frog’s belly). The overlying mucosa of the swelling is normal in appearance.
- **Shape**—it is spherical or dome shaped with only superficial half is visible.
- **Size**—it is smaller in early morning and largest just before meals, due to increased secretory activity in periods of gustatory stimulation and water absorption from the pooled mucus during inactive period.
- **Consistency**—it is soft and tends to fluctuant. It cannot empty by pressure and is non-pulsatile.
- **Fluctuation and transillumination**—both tests are positive. The ranula is typically known as brilliant translucent swelling.
- **Aspiration**—aspiration yields sticky clear fluid.
- **Plunging ranula**—when intrabuccal ranula has a cervical prolongation, it is called as deep or plunging ranula.

Fig. 26-14: Blue shaped swelling seen of ranula.

- *Origin*—it is derived from cervical sinus.
- *Location*—it lies along the posterior border of the mylohyoid muscle and appears in the submandibular region.
- *Appearance*—sometimes, plunging ranula herniates through the mylohyoid muscle and cause a swelling in suprahyoid or infrahyoid region.
- *Bidigital palpation*—to palpate plunging ranula, bidigital palpation should be performed. One finger is placed inside the mouth on the ranula and the other finger is placed on the swelling in the submandibular region. If pressure on the first finger causes sense of fluctuation on 2nd finger or vice versa, then it is plunging ranula.

Radiological Features

- *CT features*—On CT, the lesion is observed as a homogeneous, water density mass with clear boundary (Fig. 26-15A).
- *MRI features*—on MR images, the lesion shows low signal intensity on T1 weighted images; very high signal intensity on T2 weighted images. On sonograms, the plunging ranulas are observed as a well-delineated, but not round, anechoic mass (Fig. 26-15B).

Diagnosis

- *Clinical diagnosis*—blue shaped swelling in floor of mouth in lateral position will go in favor of ranula.
- *Radiological diagnosis*—MRI and CT scan will demonstrate lesion.

Differential Diagnosis

- *Sublingual dermoid*—it is more often in midline and it is not translucent, while ranula is translucent.
- *Submandibular lymph nodes swelling*—it is hard or firm in consistency.

Figs 26-15A and B: Simple ranula. (A) T1 weighted MR image shows lower signal intensity than that of muscles in the left sublingual region; (B) T2 weighted MR image of the same case. Note the remarkably high signal intensity of the lesion (Courtesy M Shimzu).

Management

- *Surgical excision*—they are best treated by surgical excision including a portion of the surrounding tissues.
- *Partial excision with marsupialization*—the major part of the cyst wall together with its overlying mucus membrane is excised.

Salivary Duct Cyst

It is also called as '*mucus retention cyst, mucus duct cyst, and sialocyst*'. It is true cyst as it is lined by epithelium.

Etiopathogenesis

- *Obstruction*—it is caused by obstruction of minor salivary gland duct which causes the backup of saliva. This continuous pressure dilates the duct and forms a cyst like lesion.

Clinical Features

- *Age and sex distribution*—retention cysts occur most often in older patients with no predilection for any sex.
- *Site*—this is most common in parotid gland. Intraorally, it is common on floor of mouth, buccal mucosa and lips.
- *Appearance*—it is slow growing and looks like mucoceles. It is soft, fluctuant swelling which appear bluish.
- *Multiple retention cyst*—in some cases, patient may develop multiple painful nodules which demonstrated as dilated ductal orifices on the mucosal surface.

Diagnosis

- *Clinical diagnosis*—it is very difficult to differentiate between mucocele and retention cyst.
- *Laboratory diagnosis*—biopsy shows lining of epithelium which consists of cuboidal, columnar or atrophic squamous epithelium surrounding thin or mucoid secretion in the lumen.

Management

- *Surgical excision*—it is treated by conservative surgical excision.
- *Antibiotics*—in some cases of multiple retention cyst, antibiotics like erythromycin and chlorhexidine mouth is helpful in relieving the pain of the patient.
- *Sialogogues*—this is helpful in stimulating salivary flow and thereby preventing an accumulation of mucin.

Asymptomatic Enlargement of the Salivary Gland

Sialosis (Sialadenosis)

It is characterized by non-neoplastic non-inflammatory enlargement of the salivary gland.

Etiopathogenesis

- *Systemic disease*—the condition is found in association with systemic diseases especially cirrhosis, diabetes, ovarian and thyroid insufficiency, alcoholism, general malnutrition, anorexia nervosa, and malnutrition.
- *Neurogenic medication*—neurogenic medication like antihypertensive drugs, psychotropic drugs and sympathomimetic drugs can cause sialosis.
- *Mechanism*—above disease may result in dysregulation of the autonomic innervations of the salivary acini causing an aberrant intercellular secretory cycle.

Clinical Features

- *Age and sex distribution*—it more commonly affects the females. As such there is no age predilection.

- *Site*—the enlargement is usually bilateral and may present a course of recurrent painless enlargement of gland. The parotid gland is more frequently affected.
- *Appearance*—swelling of the preauricular portion of the parotid gland is the most common symptom, but retromandibular portion of the gland may also be affected.

Radiological Features

- *Sialography*—on sialography, leafless tree appearance is seen (**Fig. 26-16**). This appearance is caused by compression of finer duct by hypertrophic aciner cells.

Fig. 26-16: Leafless tree appearance seen in sialosis (Courtesy M Shimzu)

Diagnosis

- *Clinical diagnosis*—bilateral non-inflammatory enlargement of parotid gland gives one clue to the diagnosis.
- *Radiological diagnosis*—leafless tree appearance seen in this disease.
- *Laboratory diagnosis*—a characteristic alteration in the chemical constituents of saliva is a distinguishing feature of sialosis. Significant elevation of salivary potassium and concomitant decrease in salivary sodium is observed.

Management

- *Control of underlying cause*—this is most important management for sialosis.
- *Partial parotidectomy*—it can be performed if swelling becomes cosmetic concern.

Allergic Sialadenitis

In some cases, it may not appear as a true hypersensitivity reaction but rather as a toxic or idiosyncratic reaction to drugs that cause decreased salivary flow, resulting in secondary infection.

Etiopathogenesis

- **Drugs**—various drugs which have been reported to cause allergic sialadenitis include sulfisoxazole, phenothiazines, iodine containing compounds, mercury, thiouracil and phenylbutazone.
- **Mechanism**—the exact mechanism of salivary gland enlargement and loss of function following administration of these drugs is not known. Most of the drugs cause decrease in capillary permeability, whereas others cause sodium and chloride retention, which subsequently leads to edema.

Clinical Features

- **Appearance**—the clinical appearance of allergic sialadenitis varies, but in most of the cases, there is bilateral parotid gland enlargement following the administration of the drug.
- **Symptoms**—the enlargement may be painful and is usually associated with conjunctivitis and skin rashes.

Diagnosis

- **Clinical diagnosis**—enlargement of gland with skin rashes and conjunctivitis.

Management

- It is a self-limiting disease and needs no treatment. But in some cases, secondary bacterial infection may develop and need treatment.

Associated with Malnutrition or Alcoholism

Asymptomatic enlargement of the parotid gland may occur in patients with nutritional deficiency, especially vitamin A and alcoholism. The patient usually gives history of long-term gradually increasing swelling of the parotid gland.

Clinically, the swelling is asymptomatic and can occur bilaterally. Palpation of enlarged gland reveals a normal tone and non-tender swelling. Simultaneous swelling of the submandibular salivary gland is a rare finding. The flow has been reported to be increased, but composition of the saliva remains unchanged, except for the elevated amylase level.

Viral Infection

Various viruses like paramyxovirus, cytomegalovirus, parainfluenza type-3 and coxsackie virus may infect salivary glands and cause its enlargement.

Mumps

It is also called as 'epidemic parotitis'. It is an acute contagious viral infection, characterized chiefly by unilateral or

bilateral swelling of the salivary glands. It mainly affects major salivary glands, but also affects the testis, meninges, pancreas, heart and mammary glands. It is caused by paramyxovirus. Incidence of mumps decreases after vaccine is available since 1967.

Transmission

- **Saliva and urine**—it usually spreads from human reservoir, by airborne infection of infected saliva and possibly urine.

Clinical Features

- **Age and sex**—it is more common in boys than in girls and most often seen between the age of 5 and 15 years.
- **Incubation period**—it is of 2 to 3 weeks and patient is contagious from one day before clinical appearance of the lesion.
- **Site**—the parotid gland is most commonly involved and it is usually bilateral. Submandibular gland may also be involved, although this is less noticeable and cause less pain. Both the parotid glands may involve simultaneously, but more commonly one parotid gland swells 24 to 48 hours after the other.
- **Prodromal symptoms**—it is preceded by onset of headache, chills, moderate fever, vomiting and pain below the ear which lasts for about one week.
- **Onset**—it is then followed by sudden onset of salivary gland swelling which is firm somewhat rubbery or elastic and without purulent discharge from the salivary gland duct.
- **Symptoms**—it produces pain upon mastication especially while eating sour food.
- **Signs**—the enlargement of parotid gland causes elevation of ear lobule. Swelling may extend upto posterior border of mandible.
- **Sublingual gland involvement**—its involvement of sublingual gland occur bilaterally. It may produce swelling in the floor of mouth.
- **Ductal papilla**—papilla on the opening of parotid duct is often puffy and reddened.
- **Course**—most of the cases are self-limiting, with salivary gland enlargement subsiding within a week.

Complications

- **Orchitis**—When mumps occur in adult males, orchitis (inflammation of the testis) is of great danger and ensues in 20% of the cases. It may result in sterility.
- **Pancreatitis**—involvement of pancreas producing acute pancreatitis often causes an elevation in serum lipase.
- **Meningitis**—meningitis and encephalitis can occur as complication of the disease.

- *Others*—deafness, mastoiditis, meningoencephalitis, epididymitis and myocarditis, have also been reported.

Diagnosis

- *Clinical diagnosis*—the presence of parotitis and accompanying systemic signs of viral infections.
- *Laboratory diagnosis*—salivary amylase level is increased. A paramyxovirus may be isolated from saliva for as long as 6 days before and up to 99 days after the appearance of salivary gland swelling.

Management

- *Vaccination*—prevention with live attenuated vaccine is the best method of controlling the disease. Vaccine should be given in 12 to 15 months of life. It should be repeated at the age of 4 to 5 years.
- *Symptomatic treatment*—symptomatic treatment is given to control pain and swelling. Mainly non-aspirin analgesic and antipyretic should be given.
- *Rest*—bedrest is recommended to minimize the chances of orchitis.
- *Diet restriction*—patient should avoid sour foods and drinks to decrease salivary gland discomfort.

Cytomegalovirus Inclusion Disease

It is also called as 'salivary gland virus disease'. It is caused by cytomegalovirus, a herpes virus. It is common in immunosuppressed adult. Although it is congenital in nature, it is usually secondary to concurrent disease which has caused debilitation.

It affects primarily in newborn infants and children, but adults are also affected. In newborns, infection is generalized and is usually fatal with involvement of liver, lungs and central nervous system. Infants who survive the infection may have permanent central nervous system involvement, including mental retardation and seizures. There may be hepatosplenomegaly, hemolytic anemia and hemorrhagic tendency. It may cause clinical disease of salivary gland, causing enlargement of the gland.

Bacterial Infection

Bacterial infection of salivary gland may be recurrent and generally develops owing to spread of microorganisms from the oral flora along the excretory duct.

Acute Bacterial Sialadenitis

It is also called as 'acute suppurative parotitis'. Most of the bacterial infection occurs as results of ductal obstruction of decreased salivary flow.

Etiology

- *Microorganisms*—it is most commonly caused by penicillin resistant *Staphylococcus aureus* or streptococci viridians.
- *Host factor*—it may be caused due to decreased host resistance, decreased salivary secretion and decreased bactericidal effect of saliva.
- *Predisposing factors*—it can occur in conditions such as dehydration, malnutrition, cancer and surgical infections.
- *Surgical procedure*—it is common when major surgical procedure is carried out in patient with poor oral hygiene.
- *Oral hygiene*—poor oral hygiene is an important contributory factor.
- *Drugs*—drugs like anti-Parkinson's, diuretics and antihistaminic have been reported to be a contributory factor for acute bacterial sialadenitis.

Clinical Features

- *Age*—most of the cases occur in adults but neonates and childhood form of the disease may occur.
- *Site*—unilateral involvement of parotid gland is common.
- *Prodromal symptoms*—it begins with the elevation of body temperature and sudden onset of pain at the angle of the jaw which is intense when the extensive infection is contained within the confines of the parotid capsule.
- *Symptoms*—the localized symptoms are accompanied by fever, leukocytosis and other generalized signs and symptoms of acute bacterial infection.
- *Signs*—parotid gland is tender, enlarged and the overlying skin is warm and red. The swelling usually causes elevation of the ear lobule (**Fig. 26-17**) and the overlying skin is characteristically warm and red.

Fig. 26-17: Enlargement of parotid gland with elevation of ear lobules in acute bacterial sialadenitis.

- *Salivary duct*—early in the disease, flecks of purulent material can be expressed from the salivary duct orifice. Intraorally, the parotid papilla may be inflamed and pus may exude or be milked from the duct of the affected gland.
- *Lymph nodes*—cervical lymphadenopathy usually develops.
- *Spread of infection*—if infection is not eradicated, pus may penetrate the gland and spread into the surrounding tissues by following routes:
 - Downwards into the deep facial plane of neck.
 - Backwards into the external auditory canal.
 - Outwards into the skin of face.
- *Postoperative parotitis*—it develops 5 to 7 days after the operation.
 - *Symptoms*—the clinical symptoms are sudden in onset with development of warm, firm or indurated swelling at the angle of jaw and over the cheek. It may be associated with local pain and tenderness. The swelling may cause trismus.
 - *Signs*—the swelling is usually brawny edematous and often causes elevation of ear lobule. The pus can be observed flowing from the opening of duct or it can be produced by a gentle milking action of cheeks.
 - *Prevention*—certain preventive measures should be taken to prevent such complication. The fluid and electrolyte balance of the body should be maintained during postoperative period. Good oral hygiene should be established prior to and after the surgery.
- *Subacute necrotizing sialadenitis*—it is salivary inflammation occurs in teenager and young adults. It involves minor salivary gland. It presents as painful nodules which is covered by intact erythematous mucosa.

Radiological Features

- *Sonography*—the affected gland shows swelling, increased vascularity, however, echo level is not decreased.
- *CT features*—when the glands are involved in cellulitis, swelling of the glands and obscuration of the glands' contour can be observed. On enhanced CT, the affected glands are seen with a higher CT values compared with the normal side because of the increased vascularity (**Figs 26-18A and B**).

Diagnosis

- *Clinical diagnosis*—tender parotid gland with elevation of ear lobule with purulent material seen from Stensen's duct.
- *Radiological diagnosis*—sonography and computed tomography will diagnose this condition.

Figs 26-18A and B: Sonograms of acute sialadenitis of the submandibular gland scanned perpendicular to the mandibular plane (left side: cranial, right side: caudal). (A) The left submandibular gland shows swelling, however, normal echo level. The black lines inside the gland are not dilated ducts, they are blood vessels; (B) The gland shows increased vascularity (Courtesy Dr M Shimizu).

Management

- *Oral hygiene*—meticulous oral hygiene should be practiced. Oral hygiene should be maintained by debridement and irrigation.
- *Diet*—soft diet should be given as chewing is painful.
- *Antibiotics*—it is treated aggressively with antibiotics. Even death can result in debilitated patients. Specimen of purulent material should be immediately sent to laboratory for sensitivity and culture. Treatment usually starts with high dose of parenteral antibiotics active against penicillin resistant *Staphylococcus*.
- *Electrolyte balance*—the patient must be adequately hydrated and the electrolyte balance should be properly maintained with intravenous fluids.
- *Stimulation of saliva*—salivation should be stimulated to facilitate drainage by sucking the sour hard candy.

- **Surgical drainage**—if improvement does not occur, surgical drainage of the affected gland should be performed.

Chronic Bacterial Sialadenitis

It is usually caused by *Streptococcus viridans*, *E coli* or *proteus*. As compared to acute parotitis, it can be seen in normal children or in adults.

Etiology

- **Ductal obstruction**—it results due to recurrent or persistent ductal obstruction.
- **Other causes**—congenital stenosis, Sjögren's syndrome, or previous viral infection or allergy.

Clinical Features

- **Age**—the childhood form commonly begins between the ages of 3 and 5 years and is usually unilateral.
- **Symptoms**—the pain is usually minimal and antibiotic therapy resolves the infection within a week.
- **Appearance**—it appears as a unilateral swelling at the angle of the jaw in a patient with the history of similar occurrence (**Fig. 26-19**).
- **Signs**—salivary flow is accompanied by flecks of purulent material. After several recurrences, fibrosis of the glandular parenchyma occurs, which leads to decreased salivary flow.

Fig. 26-19: Chronic bacterial sialadenitis presenting as swelling at angle of jaw (Courtesy Dr Chole).

Radiological Finding

- Sialograms show multiple ectasias and dilatation of the main excretory duct (**Fig. 26-20**).

Fig. 26-20: Chronic sialadenitis showing dilatation of excretory duct and multiple ectasia (Courtesy M Shimizu).

Diagnosis

- **Clinical diagnosis**—minimum pain in parotid gland area with purulent material seen from duct of gland.
- **Radiological diagnosis**—dilation and multiple ectasia seen on the radiograph.

Management

- **Radiation therapy**—it is used extensively to cause fibrosis of salivary gland, but there are then increase incidences of head and neck tumors.
- **Surgical removal**—total removal of parotid gland in cases of intractable cases. But is risk of facial nerve palsy.
- **Antibiotics injection**—intraductal injection of erythromycin or tetracycline. In it, cannulate the duct and anesthetize the area with an infusion of lidocaine directly in the duct system, which is followed by infusion of antibiotics into the duct at a concentration of 15 mg/ml.
- **Ligation of Stensen's duct**—ligation of Stensen's duct is a relatively simple procedure and can lead to fibrosis.

Chronic Sclerosing Sialadenitis

It is chronic inflammatory disease. It is also called as '*Kuttner's disease*' and is common in submandibular gland.

Pathogenesis

- It is caused by salivary ductal calculi causing subsequent pyogenic bacterial infections. It can lead to chronic inflammation, ensuring in the atrophy of mucus and serous cells and hyperplasia of the involved connective tissue leading to formation the tumor like swollen masses.

Clinical Features

- **Appearance**—there is enlargement of the glands, resulting in fibrous tumor like masses.

Radiographic Features

- *Sialectasis*—dots or blobs of contrast medium within the gland: appearance known as sialectasis caused by inflammation of the glandular tissue, producing saccular dilatation of the acini.
- *Sausage link appearance*—dilated ductal lumen and constricted ductal system (sausage-link appearance).
- *Absence of terminal branches*—in cases of chronic sclerosing sialadenitis there is absence of terminal ductal branches and presence of constricted ductal lumen within the gland.

Diagnosis

- *Clinical diagnosis*—not so specific.
- *Radiological diagnosis*—sialectasis with sausage link appearance with absence with terminal branches will diagnose this condition.

Management

There is no specific treatment for this disease. In some cases removal of gland is recommended.

Autoimmune Disorders

Sjögren's Syndrome

It is a chronic inflammatory disease that predominately affects salivary, lacrimal and other exocrine glands. It was first described by *Henrik Sjögren* in 1933. It predominately affects middle aged and elderly women.

Types

- *Primary Sjögren's syndrome*—it is also called as sicca syndrome and it consists of dry eyes (xerophthalmia) and dry mouth (xerostomia).
- *Secondary Sjögren's syndrome*—it consists of dry eyes, dry mouth and collagen disorders usually rheumatoid arthritis or systemic lupus erythematosus.

Etiology and Pathogenesis

- *Immunological findings*—the lesion in this syndrome is immunologically mediated inflammatory exocrinopathy. It begins with periductal infiltration of the tissue by mononuclear cells.
- *Autoantibodies*—the B cell hyperactivity may result from deficiency of suppressor T lymphocytes or B lymphocytes by producing autoantibodies against them. Antinuclear antibodies found in patients with Sjögren's syndrome are directed against many nuclear antigens, most commonly to DNA histone. Patients with secondary Sjögren's syndrome tend to develop antibodies against

the EBV-associated nuclear antigen antibodies RANA (rheumatoid arthritis nuclear antigen).

- *Polyclonal hyperglobulinemia*—serum immunoglobulin levels of IgG and IgM are also raised.
- *B₂ microglobulin*—serum salivary level of B₂ microglobulin is raised in minority of patients and correlates with salivary lymphocyte infiltrate.
- *Immune complex*—circulating immune complexes are found in patients with primary and secondary Sjögren's syndrome.
- *Cell mediated immune response*—delayed hypersensitivity response to skin testing is more depressed in patients with secondary Sjögren's syndrome than in patients with primary Sjögren's syndrome. Lymphokine production in response to antigen present in normal salivary tissue, is increased in patients with Sjögren's syndrome.
- *Natural killer cell activity*—augmented natural killer cell activity is impaired in some patients with Sjögren's syndrome. Although natural killer cells provide a defense against viral infection and tumor cell, their role in Sjögren's syndrome is unclear.
- *Virologic aspect*—culture of saliva does not show any specific microorganisms and serologic studies have failed to show increased titers of antibodies, except to cytomegalovirus (CMV).
- *Genetic aspect*—genetic effects of Sjögren's syndrome depend on HLA-linked and non HLA-linked genes. Relatives of a patient with Sjögren's syndrome often show a high incidence of connective tissue diseases. Primary Sjögren's syndrome is associated with HGLA-B₈ and DR₃ and secondary Sjögren's syndrome is associated with HLA-B₈ DR₄ and BW₄₄.
- *Lympho-proliferative malignancy*—enlargement of salivary glands in patients with Sjögren's syndrome is occasionally massive and associated with enlargement of regional lymph nodes, a condition known as 'pseudo lymphoma'. Malignant B cell lympho-proliferation has been shown to affect patients with Sjögren's syndrome.

Clinical Features

- *Age and sex distribution*—it is more commonly seen in middle age adults. It is most commonly found in females with 90% of cases are reported in them.
- *Eyes*—the effect on eye is called as keratoconjunctivitis sicca (dry). The patient usually complains of dry eyes or continuous irritation in the eyes. Severe lacrimal gland involvement may lead to corneal ulceration as well as conjunctivitis.
- *Connective tissue disorders*—in patients with secondary Sjögren's syndrome, rheumatoid arthritis is typically long standing and clinically obvious feature. Patients may have small joint and ulnar deviation of fingers and rheumatoid nodules.

- *Dryness of other organ*—dryness of pharynx, larynx and nose are noted by some patients. This is accompanied by lack of secretion in the upper respiratory tract, may lead to pneumonia. Vaginal dryness may be also complained by some females.

Oral Manifestation

- *Symptoms*—xerostomia is a major complaint in most of the patients. But many patients do not complain of dry mouth, but rather of an unpleasant taste, difficulty in eating dry food, soreness or difficulty in controlling dentures.
- *Signs*—Pus may be emitted from the duct. Angular stomatitis and denture stomatitis also occur.
- *Enlargement*—dry mouth may be accompanied by unilateral or bilateral enlargement of parotid gland, which occurs in about one-third of the patients and may be intermittent. Enlargement of submandibular gland may also occur.
- *Saliva*—clinically, the mouth may appear moist in early stages of Sjögren's syndrome but later, there may be lack of the usual pooling of saliva in the floor of the mouth and frothy saliva may form along the lines of contact with oral soft tissue.
- *Mucosa*—in advanced cases, the mucosa is glazed, dry and tends to form fine wrinkles. Soreness and redness of mucosa is usually the result of candidial infection.
- *Speech*—in some patients, there may be 'clicking' quality of their speech, caused by sticking of the tongue to the palate.
- *Tongue*—the tongue typically develops a characteristic lobulated, usually red surface with partial or complete depapillation. There is also decrease in number of taste buds, which leads to an abnormal and impaired sense of taste.
- *Dental caries*—dental caries is severe and gross accumulation of plaque may be obvious.
- *Periodontal disease*—periodontal disease can also occur.
- *Acute bacterial sialadenitis*—Sjögren's syndrome is the most common underlying cause of acute bacterial sialadenitis in ambulated patients. Such infections are usually either staphylococcal or pneumococcal and usually cause swelling of the salivary gland. The overlying skin is red, tender and shiny.
- *Lymph nodes*—the regional lymph nodes may be enlarged and tender.

Radiological Features

- *Sialography*—if the salivary flow rate is equivocal, sialography can be used to detect the damage. The most typical finding in Sjögren's syndrome is that of

'sialectasia', which typically produces a 'snowstorm appearance' (Fig. 26-21) as a result of leakage of contrast medium. Atrophy of ductal tree may also be seen; emptying of the duct is also typically delayed. In some cases it will show 'cheery blossom' or fruit laden branchless tree (Fig. 26-22) appearance of the obstructed ductal system.

Fig. 26-21: Snowstorm appearance seen in Sjögren's syndrome on sialography (Courtesy M Shimizu).

Fig. 26-22: Branchless fruit laden tree appearance seen in Sjögren's syndrome (Courtesy M Shimizu).

- *Salivary scintiscanning*—salivary scintiscanning with technetium pertechnetate may be useful in demonstrating impaired salivary function in patients with Sjögren's syndrome. The changes correlate with both salivary flow rate and labial gland abnormalities.

Diagnosis

- *Clinical diagnosis*—xerostomia, keratoconjunctivitis sicca with parotid enlargement may aid in diagnosis of Sjögren's syndrome
- *Sialography*—snowstorm and branchless fruit laden tree appearance.
- *San Diego criteria for diagnosis of Sjögren's syndrome.*

Primary Sjögren's syndrome	Secondary Sjögren's syndrome
• Ocular dryness—Schirmer's test less than 8 mm wetting per 5 minute, positive rose Bengal staining of cornea • Dry mouth—decreases parotid flow Lashley cups method • Systemic autoimmunity—elevated Rh factors, elevated antinuclear antibody and presence of anti-SS and anti-SS-B antibodies	• Signs and symptoms of primary Sjögren syndrome • Rheumatoid arthritis, SLE, Polymyositis, scleroderma or biliary cirrhosis • Exclusion of sarcoidosis, pre-existing lymphoma, HIV, Hepatitis B or C, primary fibromyalgia and known cause of keratitis sicca and salivary gland enlargement.

Laboratory Investigations

- *Rose Bengal staining test*—keratoconjunctivitis sicca is characterized by corneal keratotic lesion, which stains pink when 'rose Bengal' dye is used.
- *Schirmer test*—the reduced lacrimal flow rate is measured by this test. A strip of filter paper is placed in between the eye and the eyelid to determine the degree of tears which should be measured in millimeter. When the flow is reduced to less than 5 mm in a 5 minute sample, patient should be considered positive for Sjögren's syndrome.
- *Sialometry*—salivary flow rate estimation is a sensitive indicator of salivary gland function. Parotid glands make the major contribution to total salivary flow and are the most consistently affected glands in patients with Sjögren's syndrome. Stimulated flow rate in symptomatic primary and secondary Sjögren's syndrome is usually below 0.5 to 1.0 ml/minute (normal 1 to 1.5 ml/minute).
- *Sialochemistry*—parotid saliva in Sjögren's syndrome contains twice as much total lipid and has elevated content of phospholipids and glycolipids than the normal saliva. The sodium chloride and phospholipids levels are higher in saliva of Sjögren's syndrome patient.
- *Immunologic*—a routine autoantibody profile can usually be carried out with the particular aim of detecting rheumatoid and antinuclear factors.
- *Hematological investigations*—it is necessary, particularly to exclude anemia. ESR or plasma viscosity, leucopenia occasionally may also be found.
- *Microbiological investigations*—a swab from oral mucosa should be taken to confirm candidiasis, if there is soreness and erythema. Examination of pus is also

of course essential as a guide to antimicrobial treatment, if acute sialadenitis develops.

- *Salivary gland biopsy*—the changes in minor glands of lower lip show close correlation with those in the major salivary glands and provide a safe and convenient source of material.

Management

- *Ocular lubricant*—keratoconjunctivitis is treated by instillation of ocular lubricants, such as artificial tears coating methylcellulose and xerostomia is treated by saliva substitutes.
- *Oral hygiene maintenance*—scrupulous oral hygiene and frequent fluoride application is indicated to reduce these problems.
- *Salivary stimulant*—bromhexine, pilocarpine and cevimeline can be used to stimulate salivary flow.
- *Surgery*—surgery for enlargement of salivary gland is only recommended when the enlargement is causing discomfort to the patient.

Mikulicz's Disease or Benign Lympho-epithelial Lesion

It was first described by Mikulicz in 1888 as symmetric or bilateral, chronic, painless enlargement of lacrimal and salivary glands. It exhibits both inflammatory and neoplastic characteristics. Initially, Mikulicz's disease was confused with disease processes such as leukemia and tuberculosis and in these cases, it is called as *Mikulicz syndrome*. Mikulicz's disease is term used only for benign lymphoepithelial lesion involving parotid and lacrimal gland.

Clinical Features

- *Age and sex*—it occurs more commonly in women in middle and later life.
- *Site*—it is manifested as a unilateral or bilateral enlargement of parotid and/or submandibular gland.
- *Prodromal symptoms*—the onset of the lesion is some times associated with fever, upper respiratory tract infection, oral infection, tooth extraction or some local inflammatory disorders.
- *Symptoms*—in some cases, there is mild local discomfort, occasional pain and xerostomia.
- *Signs*—there is often diffuse, poorly outlined enlargement of salivary gland rather than formation of a discrete tumor nodule. The enlargement varies in size but generally few centimeters in diameter. There is history of alternating increases and decreases in the size of mass, from time to time.
- *Duration*—the duration of the tumor mass may be only a few months or many years.

Diagnosis

- *Clinical diagnosis*—unilateral or bilateral enlargement of parotid and lacrimal gland may aid to diagnosis.
- *Laboratory diagnosis*—biopsy shows solid nest or clumps of poorly defined epithelial which termed as 'epimyoepithelial islands'.

Management

- *Surgical excision*—surgical removal of involved gland should be carried out. Prognosis is good.

Uveoparotid Fever

It is a form of sarcoidosis and it is also called as 'Heerfordt's syndrome'.

It consists of a triad of—

- *Uveitis*—inflammation of uveal tract of the eye.
- *Parotid swelling*—firm, painless and bilateral enlargement of parotid gland.
- *Facial palsy*

Etiology

- *Infection*—tuberculosis was earlier thought to be the causative agent.
- *Hereditary*—hereditary factors also play an important role in this syndrome.
- *Autoimmune*—autoimmune mechanism of the body can also be responsible.

Clinical Features

- *Age*—it usually occurs in 3rd and 4th decades of life.
- *Prodromal symptoms*—prodromal symptoms lasting from a few days to several weeks are the usual initial signs of the disease and patient complains of fever, malaise, weakness, nausea and night sweat.
- *Appearance*—it appears as a bilateral, firm, painless parotid swelling. The parotid swelling lasts from several months to several years.
- *Involvement of other gland*—submandibular, sublingual and lacrimal gland swelling may develop independently or during the course of the parotid swelling.
- *Sarcoidial lesion*—sarcoidial lesion may also be found in the oral cavity.
- *Uveitis*—it is an inflammation of the uveal tract, is a feature of this disease. Although ocular symptoms are usually bilateral, they become more apparent before the appearances of parotid swelling.
- *Nerve involvement*—the most common nerve involved is facial nerve. there is unilateral or bilateral seventh nerve paralysis. The neurological signs may precede, follow or appear simultaneously with parotid swelling. There

is trigeminal paresthesia, eyelid ptosis, polyneuritis, intercostal neuralgia and spinal nerve impairment accompanied by weakness and muscle atrophy have been reported.

Radiographic Features

- The sialographic picture merely shows the severity and duration of the disease process within the particular gland.

Diagnosis

- *Clinical diagnosis*—parotid swelling with facial palsy and uveitis will diagnose this syndrome.
- *Laboratory diagnosis*—it will reveal a characteristic sarcoid nodule.

Management

- *Corticosteroids*—it is largely asymptomatic as it may undergo spontaneous remission. Corticosteroid can be used in cases of acute exacerbation.

Recurrent Non-specific Parotitis

It occurs in children as well as in adults, with the average age of onset being between 3 and 4 years. The disease may disappear with puberty, but often progresses into adult life. Males are more commonly affected than females. A congenital defect and allergy have been suggested as the possible causes.

The disease is characterized by a sudden onset of parotid swelling. Both unilateral and bilateral parotid involvement has been reported. Swelling develops rapidly and may persist for a few days to a year. Diminished salivary flow has also been noted during the period of both exacerbation and remission. Moderate rise in total serum protein. Serum gammaglobulin levels may also be increased.

Tumors of Salivary Glands

It is important to note that neoplasms arise not only in major salivary glands, but also in minor salivary glands.

Classification

See Tables 26-1 and 26-2.

Firmness of the Tumor

Firmness results from dense aggregates of nests and cords of closely packed tumor. Fibrous tissue and hyaline area as well as cartilage like and bone like tissue. Softness results from fluid production and its retention phenomenon.

Table 26-1: WHO 1991

Adenoma

- Pleomorphic adenoma
- Myoepithelioma
- Basal cell adenoma
- Warthin's tumor
- Oncocytoma
- Canalicular adenoma
- Sebaceous adenoma
- Ductal papilloma
 - Inverted ductal papilloma
 - Intraductal papilloma
 - Sialadenoma papilliferum
- Cystadenoma
 - Papillary cystadenoma
 - Mucinous cystadenoma
- Monomorphic adenoma
 - Adenolymphoma (Warthin's tumor)
 - Oxyphilic adenoma (oncocytoma)
 - Other types
 - Basal cell adenoma
 - Canalicular adenoma
- Mucoepidermoid tumor
- Acinic cell tumor

Carcinoma

- Acinic cell carcinoma
- Mucoepidermoid carcinoma
- Adenoid cystic carcinoma
- Polymorphous low grade adenocarcinoma
- Epithelial myoepithelial carcinoma
- Basal cell adenocarcinoma
- Sebaceous carcinoma
- Papillary cystadenocarcinoma
- Mucinous adenocarcinoma
- Oncocytic carcinoma
- Salivary duct carcinoma
- Adenocarcinoma
- Malignant myoepithelioma
- Carcinoma in pleomorphic adenoma (Malignant pleomorphic adenoma)
- Squamous cell carcinoma
- Small cell carcinoma
- Undifferentiated carcinoma
- Other carcinomas

Non-epithelial tumors**Malignant lymphoma****Secondary tumors****Unclassified tumors****Tumor like lesions**

- Sialadenosis
- Oncocytosis
- Necrotizing sialometaplasia
- Benign lymphoepithelial lesions

Table 26-2: Clinical

Benign seldom recurrent

- Warthin's tumor
- Oncocytoma
- Monomorphic salivary adenomas

Benign, often recurrent

- Pleomorphic adenoma
- Mucoepidermoid tumor (low grade)
- Acinic cell tumor

Malignant

- Carcinoma in pleomorphic adenoma
- Adenoid cystic carcinoma
- Acinic cell tumor
- Mucoepidermoid tumor (high grade)
- Squamous carcinoma
- Adenocarcinoma
- Undifferentiated carcinoma

Firm tumor	Soft tumor
• Pleomorphic adenoma • Adenoid cystic carcinoma • Mucoepidermoid tumor of high grade • Carcinoma in pleomorphic adenoma • Acinic cell carcinoma • Oncocytoma	• Well differentiated Mucoepidermoid tumor • Papillary cyst adenoma • Mucus producing adenocarcinoma • Warthin's tumor

Clinical Staging of Salivary Gland Tumors**By Spiro**

Staging of salivary gland neoplasms appear to be initiated by Spiro. It is as follows:

- T_1 —0 to 3 cm and solitary and freely mobile and CRVII intact.
- T_2 —3.1 to 6 cm and solitary and freely mobile or skin fixation and CRVII intact.
- T_3 —6 cm or multiple nodules or ulceration or deep fixation or CRVII dysfunction.
- Patient with T_1 and T_2 lesion are placed into stage I and II respectively.
- Any patient with clinical evidence of metastasis of lymph nodes or with T_3 lesion is considered to be in stage III.

By American Joint Committee**Primary tumor**

- T_x —tumor that cannot be assessed by the rules.
- T_0 —no evidence of primary tumor.
- T_1 —tumor 2 cm or less in diameter, without significant local extension.
- T_2 —tumor 2-4 cm in diameter without significant local extension.
- T_3 —tumor more than 4 cm but not more than 6 cm in diameter without significant local extension.

- T_{4a} —tumor over 6 cm in diameter without significant local extension.
- T_{4b} —tumor of any size with significant local extension.
- *Nodal involvement (N)*
 - N_x —regional lymph node cannot be assessed.
 - N_0 —no regional lymph node metastasis
 - N_1 —clinical or histologically positive regional lymph nodes.
- *Distant metastasis (M)*
 - M_x —distant metastasis cannot be assessed.
 - M_0 —no distant metastasis.
 - M_1 —distant metastasis.
- *Stage grouping is performed as follows.*
 - *Stage I*— $T_1N_0M_0$ or $T_2N_0M_0$
 - *Stage II*— $T_3N_0M_0$
 - *Stage III*— T_1 or $T_2, N_1 M_0$, or T_{4a} or $T_{4b} N_0 M_0$
 - *Stage IV*— $T_3 N_1 M_0$, T_{4a} or $T_{4b} N_1 M_0$, any T any N M_1

Benign Tumors

Pleomorphic Adenoma

The term pleomorphic adenoma was suggested by Willis characterizing the unusual histological pattern of the lesion (pleomorphic or mixed appearance). It is a benign mixed tumor of the salivary gland. It is also called as 'iceberg tumor', 'endothelioma', 'branchioma', or 'enchondroma'. It is most common salivary gland tumor.

Pathogenesis

- *Myoepithelial cells*—myoepithelial cells are responsible for morphologic diversity of tumor including production of fibrous, mucinous, chondroid and osseous structures.
- *Differentiation of ductal reserve cells*—intercalated duct reserve cells can differentiate into ductal and myoepithelial cells and the later can then undergo mesenchymal metaplasia since they inherently have smooth muscle like properties.
- *Neoplastic altered epithelial cells*—a neoplastically altered epithelial cell with potential for multidirectional differentiation may be responsible for pleomorphic adenoma.

Clinical Features

- *Sex and age*—women to men ratio is 6:4. It is common in 4th to 6th decades but also seen in young adults and children
- *Site*—parotid 90% and intraoral palatal gland on lip. In parotid involvement, superficial portion is most commonly affected (Fig. 26-23).

Fig. 26-23: Swelling of parotid gland seen in cases of pleomorphic adenoma.

- *Symptoms*—small, painless, quiescent nodule which slowly begins to increase in size, sometimes intermittently.
- *Shape*—the tumor tends to be round or oval when it is small, as it grows bigger it becomes lobulated. In some cases, intraorally swelling may be observed (Fig. 26-24).

Fig. 26-24: Intraoral view pleomorphic adenoma showing swelling in the palate (Courtesy Dr Parate).

- *Size*—it may increase to cricket ball size or even more, weighing in pounds and in intraoral cases, not more than 1 to 2 cm in diameter. If neglected lesion can grow bizarre proportions.
- *Dumbbells shaped appearance*—in some cases, lesion grows in medial direction between ascending ramus and stylomandibular ligament resulting in dumbbell shaped appearance.
- *Surface*—its surface is smooth. Sometime, it is bosselated and is occasionally crossed by deep furrows.

- *Fixation*—no fixation, either to deeper tissues or overlying skin.
- *Consistency*—it is firm and rubbery to feel. Sometimes cystic degeneration may be seen.
- *Palatal tumor*—it is seen on lateral aspect of the palate. They are smooth surface and dome shaped (**Fig. 26-25**).
- *Signs of malignant transformation*—accelerated growth rate, tumor irregularity on palpations, necrosis and painful ulceration and facial nerve involvement.

Fig. 26-25: Dome-shaped swelling on lateral aspect of palate due to pleomorphic adenoma of the minor salivary gland (Courtesy Dr Chole).

Diagnosis

- *Clinical diagnosis*—smooth surface enlargement in the parotid region will suspect pleomorphic adenoma.
- *Sialography*—ball in hand appearance seen (**Fig. 26-26**).
- *CT diagnosis*—this will also help to know exact extension of location (**Fig. 26-27**).
- *Laboratory diagnosis*—biopsy shows cuboidal cells arranged in tubes or duct-like structures, which begin to resemble the normal ductal epithelium. Duct-like spaces contains eosinophilic coagulum.

Management

- *Surgical excision.*
 - *Parotid gland*—tumor and the involved lobe of gland is removed.
 - *Submaxillary gland*—removal of the gland and tumor in continuity.
 - *Intraoral lesion*—extracapsular incision.
 - *Hard palate*—excised with overlying mucosa.
 - *Lip, soft palate*—enucleation or extracapsular excision.
- *Recurrence rate*—recurrence rate is 5 to 30% due to hypocellularity, incomplete resection and encapsulation.

Fig. 26-26: Ball in hand appearance seen on sialography in pleomorphic adenoma (Courtesy M Shimizu).

Fig. 26-27: CT scan showing extension of pleomorphic adenoma involving parotid gland

Monomorphic Adenoma

Monomorphic adenoma is divided into three groups by WHO, i.e. adenolymphoma (Warthin's tumor), Oxyphilic adenoma (oncocyoma) and other histologic patterns like basal cell adenoma and canalicular adenoma. But

Warthin's tumor and Oxyphilic adenoma are recognized separate entity nowadays; so only included in monomorphic adenoma are basal cell adenoma and canalicular adenoma.

Basal Cell Adenoma

It derived its name by baseloid appearance of the tumor cells.

Clinical Features

- *Age and sex*—it is more common in females. Older age group, usually over 60 years of age are affected.
- *Site*—it occurs primarily in major salivary glands particularly in the parotid gland and intraorally, upper lip.
- *Symptoms*—the tumor is usually painless and is characterized by slow growth.
- *Membranous basal cell adenoma*—this type of variant of basal cell adenoma occurs in association with appendage tumors like dermal cylindroma and trichoepitheliomas.

Diagnosis

- *Clinical diagnosis*—it is difficult to make clinical diagnosis.
- *Laboratory diagnosis*—biopsy shows fairly well defined connective tissue capsule. The cells are isomorphic and baseloid with round to oval nuclei.

Management

- *Surgical excision*—it is treated by surgical excision and recurrence is seldom seen.

Canalicular Adenoma

It occurs exclusively in minor salivary gland.

Clinical Features

- *Age and sex*—it is common in patient over the age of 60 years with no sex predilection.
- *Site*—it originates primarily in the intraoral accessory glands. It occurs in upper lips followed by palate, buccal mucosa and lower lip.
- *Symptoms*—it presents as a slowly growing, well circumscribed, firm nodule.
- *Signs*—it is firm and fluctuant to palpation.

Diagnosis

- *Clinical diagnosis*—firm fluctuant swelling on upper lip may suspect the diagnosis of canalicular adenoma.

- *Laboratory diagnosis*—biopsy shows long strands or cords of epithelial cells, arranged in a double row. It shows 'party wall'.

Management

- *Surgical excision*—it can be treated by simple enucleation and surgical excision. Recurrence rate is rare.

Warthin's Tumor

It is also called as 'adenolymphoma' and 'primary cystadenoma lymphomatosum'. This tumor was first described by Albrecht and Arzt but it usually bears the name of Warthin in the recognition of the pathologist who first described it in USA in 1929.

Development

- *Heterotrophic salivary gland tissue*—tumor arises from salivary gland tissue entrapped with para-parotid or intra-parotid lymph nodes during embryogenesis.
- *Delayed hypersensitivity disease*—it is most likely a delayed hypersensitivity disease, the lymphocytes being an immune reaction to the salivary ducts which undergo oncocytic change.
- *Secretory immune response*—Hsu has suggested that it is an exaggerated secretory immune response.
- *Other factors*—other factors like smoking and Epstein-Barr virus have also been responsible for Warthin tumor.

Clinical Features

- *Age and sex*—it is common in men (male to female ratio is 5:1). It is common in 6th decade.
- *Site*—the tumor occurs almost exclusively in the parotid gland. It always occurs in the lower portion of the parotid gland. The tumor is generally superficial, lying just beneath the parotid capsule or protruding through it.
- *Symptoms*—the usual complaint is painless slow growing tumor over the angle of jaw. Involvement may be bilateral or may be multifocal.
- *Size and shape*—the tumor does not attain a large size and the usual size is 1-3 cm in diameter. It is spherical in shape.
- *Surface*—it is smooth (**Fig. 26-28**) and it is well circumscribed, movable.
- *Consistency*—it classically feels doughy and compressible on palpation. It is firm on palpation and is clinically indistinguishable from other benign lesions of parotid gland.

Radiological Features

- *CT/MRI features*—Warthin tumor is observed as a round or oval shaped mass with smooth, well-delineated

Fig. 26-28: Smooth swelling occurs due to mass in tail of parotid gland in Warthin tumor (Courtesy Dr Chole).

contour. It contains cystic parts, which are seen on CT, MR images (**Fig. 26-29**) and sonograms.

- **Sonography**—on sonograms, this tumor is observed as a very clearly delineated mass with multiple cystic areas. On Doppler mode, relatively abundant vascularization is observed.

Fig. 26-29: Warthin tumor: T1 weighted MR image shows round shaped mass with smooth, well-delineated contour in the lower pole of the left parotid gland. Signal intensity is higher than that of muscle (Courtesy Dr Shimizu).

Diagnosis

- **Clinical diagnosis**—difficult to diagnose.
- **Laboratory diagnosis**—it is an adenoma exhibiting cyst formation, with papillary projections into the cystic spaces and lymphoid matrix showing germinal centers.

Management

- **Superficial parotidectomy**—it is done as tumor is usually located in superficial part of the parotid gland.

Oncocytoma

It is also called as '*oxyphilic adenoma*', '*acidophilic adenoma*'. It is an uncommon tumor composing less than 1% of salivary neoplasms. The term oncocytoma is derived from the resemblance of these tumor cells to apparently normal cells, which have been termed as '*oncocytes*'. These cells are predominately seen in duct lining of glands in elderly persons.

Clinical Features

- **Age and sex**—it is more common in women than in men and occurs almost exclusively in older persons.
- **Site**—it usually occurs in the parotid gland.
- **Size**—the tumor usually measures 3 to 5 cm in diameter and appears as a discrete encapsulated painless mass (**Fig. 26-30**) which is sometimes nodular. Pain is generally absent.
- **Oncocytosis**—an interesting condition called '*oncocytosis*' of parotid gland has been described. It is characterized by nodules of oncocytes involving the entire gland or a large portion. It is usually bilateral.

Fig. 26-30: Discrete encapsulated painless mass seen in oncocytoma (Courtesy Dr Parate).

Diagnosis

- *Clinical diagnosis*—it is difficult to differentiate with other benign condition.
- *Laboratory diagnosis*—biopsy shows large cells with eosinophilic cytoplasm, distinct cell membrane. It is arranged in rows and cords.

Management

- *Surgical excision*—surgical excision of tumor should be carried out. Facial nerve should be preserved.

Myoepithelioma

It is an uncommon salivary gland tumor. It occurs in adults and has equal sex distribution. Parotid gland is most commonly involved and the palate is the most frequent intraoral site of occurrence. The clinical features are same as pleomorphic adenoma.

The tumor is composed of spindle shaped or plasmacytoid cells or combination of the two cell types. These cells may be set in myxomatous background, which may vary from scanty to copious. It is managed by surgical excision.

Ductus Papillomas

These are the group of tumor characterized microscopically by papillomatous pattern.

Types

- *Simple or intraductal papilloma*—appears as submucosal swelling.
- *Inverted ductal papilloma*—is present most commonly on lip.
- *Sialadenoma papilliferum*—is seen most commonly on palate (**Fig. 26-31**).

Fig. 26-31: Ductus papilloma presenting as swelling on hard palate.

Clinical Features

- *Simple or intraductal papilloma*—it is present as an exophytic lesion with a papillary surface and is pedunculated. It is usually reddish in color and present on the buccal mucosa or palate. It is ill-defined.
- *Inverted ductal papilloma*—it is present asymptomatic nodules of the oral mucosa of adults. It is more commonly seen on lip. It may show pit or indentation in the overlying surface mucosa.
- *Sialadenoma papilliferum*—the lesion occurs in adults as an exophytic papillary lesion of the hard palate.

Diagnosis

- *Clinical diagnosis*—it is difficult to make. But small swelling in relation with minor salivary gland, one should suspect ductal papilloma.
- *Laboratory diagnosis*—on biopsy, it shows multiple exophytic papillary projection which is covered by stratified squamous epithelium.

Management

- *Surgical excision*—it is best treated by conservative surgical excision.

Malignant Tumors

Peripheral Mucoepidermoid Carcinoma

The term mucoepidermoid tumor was introduced in 1945 by Stewart, Foote and Becker. It accounts for 6 to 9 % of the salivary gland tumors and for about 1/3rd of all malignant tumors of the salivary glands. It consists, of both, mucus secreting as well as epidermoid type of cells as its name suggests.

It is of mainly two types, i.e. benign and malignant based upon clinical nature and histologic feature of the lesion.

Clinical Features

- *Age and sex*—it occurs in equal distribution in men and women and occurs in the 3rd and 5th decade.
- *Site*—about 60% occur in parotid gland (**Fig. 26-30**) and 30% in the minor salivary glands, especially those of the palate. It can be seen on buccal mucosa, tongue and retromolar area.
- *Onset*—it appears as a slowly enlarging painless mass, which simulates pleomorphic adenoma (**Figs 26-32A and B**).
- *Symptoms*—pain and facial nerve palsy can be seen in some patients. Other findings such as lacrimation, trismus, nasal discharge, and blood tinged saliva can also be seen.

Figs 26-32A and B: Mucoepidermoid carcinoma of parotid gland. (A) Extraoral view, (B) Intraoral view (Courtesy Dr Parate).

- *Low grade tumor*—the tumor of low grade malignancy usually appears as a slowly enlarging, painless mass, which stimulates pleomorphic adenoma. It seldom exceeds 5 cm in diameter (**Fig. 26-33**).
- *High grade malignancy*—the tumor of high grade malignancy grows rapidly and does produce pain as an early symptom. It tends to infiltrate the surrounding tissues and in high percentage of cases it metastasizes to the regional lymph nodes. Distant metastases to lungs, bones, brain and subcutaneous tissue are common. In some cases, extraoral ulceration can also be seen (**Fig. 26-34**).
- *Minor gland tumors*—it appears as asymptomatic tumors which is blue or red in color.

Diagnosis

- *Clinical diagnosis*—it is difficult to make clinical diagnosis of mucoepidermoid carcinoma.

Fig. 26-33: Mucoepidermoid tumor occurring on buccal mucosa (Courtesy Dr Soni).

Fig. 26-34: Mucoepidermoid carcinoma showing extraoral ulceration

- *Radiological diagnosis*—computed tomography will diagnose this condition (**Fig. 26-35**).
- *Laboratory diagnosis*—biopsy shows mucus-secreting cells, epidermoid type cells and intermediate cells. Biopsy also shows sheets or nests of epidermoid cells and similar nests of mucus cells, usually arranged in a glandular pattern and showing microcyst formation.

Management

- *Subtotal parotidectomy*—early stage tumor is managed by subtotal parotidectomy and facial nerve preservation.
- *Total removal*—advanced cases need total removal of the parotid gland.

Fig. 26-35: Computed tomography showing growth on right side in parotid gland (arrow).

- *Radical neck dissection*—it is indicated for the person who has clinical evidence of metastasis.
- *Radiotherapy*—it can be given in some cases of intermediate type of mucoepidermoid carcinoma.

Central or Intraosseous Mucoepidermoid Carcinoma

It is an epithelial tumors originating in the bone and is believed to be derived from salivary gland.

Origin

- *Entrapment of retromolar mucus gland*—it may originate from entrapment of retromolar mucus glands within the mandible, which subsequently undergo neoplastic transformation.
- *Embryonic remnants of submaxillary gland*—it may also form from developmentally retained embryonic remnants of the submaxillary gland within the mandible and neoplastic transformation of the mucus secreting cells commonly found in the epithelial lining of dentigerous cyst.

Clinical Features

- *Age and sex distribution*—it is most commonly seen in middle age individual. It is more common in females than males.
- *Site*—it occurs in mandible in premolar-molar area. It does not extend anteriorly beyond the premolar region.
- *Symptoms*—patient complains of painless swelling. There may be paresthesia of inferior alveolar nerve.
- *Sign*—swelling may cause facial asymmetry. Tenderness is present. Regional lymph nodes are enlarged.

Radiological Features

- *Site*—it occurs in premolar-molar area of mandible, above mandibular canal.
- *Appearance*—it presents as a unilocular or multilocular expansile mass (Fig. 26-36).
- *Margin*—it is most often well defined, well corticated and often crenated or undulating in nature.
- *Soap bubble or honeycomb appearance*—lesion may have soap bubble or honeycomb internal structure.

Fig. 26-36: Multilocular lesion seen in premolar molar area (Courtesy Dr Parate).

- *Effect on surrounding structure*—the buccal and lingual cortical plate, inferior border of the mandible, alveolar crest may be thinned and grossly displaced. The mandibular canal is depressed or pushed laterally or medially. Lamina dura of the teeth may be lost.

Diagnosis

- *Clinical diagnosis*—not so specific.
- *Radiological diagnosis*—soap bubble and honeycomb appearance may be seen.

Differential Diagnosis

- *Ameloblastoma*—radiologically, it is difficult to differentiate. Diagnosis should be confirmed by histopathological investigation.
- *Odontogenic myxoma*—there is history of missing tooth.
- *Central giant cell granuloma*—it frequently crosses the midline.

Management

- *Surgical excision*—it is treated by surgical excision of tumor.
- *Neck dissection*—neck dissection should be carried out in case of metastatic.

- *Adjunctive radiotherapy*—postoperative radiation therapy may be required for control of metastasizing disease.

Acinic Cell Tumor

It is also called as '*acinic cell or serous cell adenoma*'. It accounts for approximately 1% of all salivary gland tumors. It shows serous acinar differentiation.

Clinical Features

- *Age and sex*—it occurs in middle age and twice common in women.
- *Site*—it arises exclusively in the superficial lobe and tail of the parotid gland. The most common intraoral sites are the buccal mucosa and lip.
- *Symptoms*—it is painless and grows slowly.
- *Signs*—exact delineation of the lesion is difficult and attachment to the overlying skin and muscle may occur.
- *Progress*—some of these lesions run a rapid course with hematogenous and lymphatic metastases, while others are more slowly progressive. Locally invasive growth may be encountered in some lesions.

Diagnosis

- *Clinical diagnosis*—not possible.
- *Laboratory diagnosis*—biopsy shows thin capsule, which composed of cells of varying degrees of differentiation. Well differentiated cells bear remarkable resemblance to normal acinar cells, whereas less differentiated cells resemble embryonic ducts and immature acinar cells.

Management

- *Lobectomy*—superficial lobe of the parotid gland should be excised, is the treatment of choice. Recurrence rate varies from 8 to 59%.

Adenoid Cystic Carcinoma

It is also called as '*cylindroma*', '*adenocystic carcinoma*' and '*baseloid mixed tumor*'. It is best recognized salivary gland malignancy.

Clinical Features

- *Age*—it occurs in the 5th and 6th decade of life.
- *Site*—most common glands involved are the parotid, sub-maxillary and the accessory glands in palate and tongue.
- *Symptoms*—the most common initial symptom is presence of mass followed by local pain, facial nerve paralysis in case of parotid tumor and tenderness.
- *Signs*—some of the lesions exhibit surface ulceration. Other findings include nasal obstruction, proptosis,

sinusitis, ear infection, epistaxis, signs of cranial nerve involvement and visual disturbances.

- *Metastasis*—the incidence of metastases is more and the organs involved include cervical lymph nodes, lungs, brain, liver and kidneys.

Radiological Features

- *Appearance*—CT scan will demonstrate destructive lesion (Fig. 26-37).

Fig. 26-37: This tumor shows bone destruction and absorption of the dental root. Some fine calcification can also be seen in the tumor (Courtesy Dr Shimizu).

Diagnosis

- *Clinical diagnosis*—not possible.
- *Laboratory diagnosis*—biopsy shows basal cells arranged in anastomosing cords or may contain a mucoid material producing the typical cribriform '*honeycomb*' or '*Swiss cheese*' pattern. The stromal connective tissue becomes hyalinized and surrounds the tumor cells, forming a structural pattern of cylinder from which the lesion originally derived the name '*cylindroma*'.

Management

- *Surgical excision*—surgical excision is the treatment of choice. Recurrence rate is about 60 to 92%. Long-term follow up is hence essential.
- *Adjunct radiotherapy*—surgery should be accompanied by radiation therapy.

Adenocarcinoma

It is a malignant epithelial tumor showing tubules or papillary glandular formation. All adenocarcinoma are

highly malignant and metastasize to regional lymph nodes and general viscera. Computed tomography will diagnose this malignant tumor (**Fig. 26-38**).

Fig. 26-38: Enhanced CT shows round, slightly enhanced mass with bone invasion in the lingual side of the left retro-molar region. Bone invasion suggests malignant nature of this tumor

Malignant Pleomorphic Adenoma

It is also called as '*malignant mixed tumor*'. It is uncertain that these tumors represent the previously benign lesions which have undergone transformation into malignant form or are malignant lesion right from the onset. It accounts for 1% of all parotid tumors and 7% of all malignant tumors.

Clinical Features

- **Age**—the tumor occurs from 2nd to 9th decades, but most frequently in 5th and 6th decade. The average age of patients with malignant pleomorphic adenoma is about ten years older than the patients with benign form of the disease.
- **Symptoms**—pain is more frequently a feature of malignant, than the benign pleomorphic adenoma
- **Size**—the tumors are usually larger than benign ones.
- **Signs**—there is often fixation of the tumor to underlying structures as well as to overlying skin or mucosa.

Radiological Features

- **CT features**—CT/MRI features will show malignant changes in the tumors (**Fig. 26-39**).

Diagnosis

- **Clinical diagnosis**—not possible.
- **Laboratory diagnosis**—biopsy shows malignant component. There is presence of nuclear hyperchromatism and pleomorphism, increased or abnormal mitosis and destruction of normal tissues.

Fig. 26-39: T1 weighted MR image shows several masses in the left parotid gland. The relatively well-delineated mass in the middle shows low signal intensity (Courtesy Dr Shimizu).

Management

- **Surgical**—surgical excision with local node dissection should be carried out. These neoplasms exhibit a high recurrence rate after surgical removal as well as a high incidence of regional lymph node involvement.

Epidermoid Carcinoma

It is also called as '*squamous cell carcinoma of salivary glands*'. It is thought to be ductal in origin, since duct may undergo squamous metaplasia with ease. It exhibits infiltrative properties and early metastasis. It recurs readily. It is not a common lesion and arises more frequently in the major salivary gland. The combined use of surgery and radiotherapy is more beneficial.

Undifferentiated Carcinoma

The tumor is composed of round or spindle cells that are poorly differentiated. Undifferentiated carcinomas infiltrate the surrounding structures and readily metastasize to cervical lymph nodes.

Metastatic Carcinoma

Salivary glands may be a site for tumor metastases, since the parotid gland contains as many as 20 to 30 lymph follicles. Parotid and paraparotid lymph nodes are favored sites for metastases from malignancy of the temple, scalp and ear and occasionally from the face, neck and palate. The most common metastasizing tumors are melanoma and squamous cell carcinoma.

Connective Tissue Tumors

Hemangioma is the only common tumor of this group and the most frequently seen in young infants. The involved glands appear hypertrophied. There is blue discoloration of the overlying skin. Lipoma may occur in the parotid gland. The facial nerve, occasionally gives rise to a neural tumor. True sarcoma is extremely rare.

Necrotizing Sialometaplasia

It is a non-neoplastic inflammatory self-healing reaction of salivary gland tissues, which both clinically and histologically mimics a salivary gland malignancy. It usually affects the minor salivary glands. It was predicted that trauma causes ischemia of the minor salivary glands. This benign self-limiting lesion has been often confused with malignancy thereby causing unnecessary surgery.

Etiology and Pathogenesis

- *Local ischemia*—it may be due to physical, chemical, infective or local vasculitis.
- *Trauma*—trauma from various factors such as denture wearing and recent surgery may be a causative factor.
- *Other factors*—in some cases, smoking and alcohol intake can lead to this condition. It can also occur in upper respiratory tract infection.

Clinical Features

- *Age and sex*—it is more common in males than females. Occurs in 4th and 5th decade.
- *Site*—most of the cases occur in palate, although cases of lip or retromolar pad also have been reported.
- *Onset*—there may be early mild swelling which appears as non-ulcerated swelling (**Fig. 26-40**).

Fig. 26-40: Bilateral swelling seen in palatal region due to necrotizing sialometaplasia. Slight ulceration seen on the swelling.

- *Symptoms*—it is usually painless or may cause only slight pain. The patient may have numbness in the palate, or area of 'looseness' in palate. Pieces of tissue may fall out from the palate. There may be referred pain to ear or pharynx.
- *Signs*—the lesion begins as a larger ulcer or ulcerated nodule, which may be unilateral or bilateral. The ulcer is well demarcated from surrounding normal tissue and often has an inflammatory reaction around the edge of the lesion. Margins of ulcer in some cases, may be indurated and inflamed. The lesion is covered by an inflammatory exudate and necrotic debris, however, the margins of ulcer are usually clean, sharp and the granulation tissue often can be seen at the superficial aspect.
- *Size*—the lesion itself is most often a deep, craterlike, non-draining ulcer 1 to 3 cm in diameter.

Diagnosis

- *Clinical diagnosis*—ulcerative swelling in the palate will aid in the diagnosis.
- *Laboratory diagnosis*—in biopsy, it shows acinar necrosis and squamous metaplasia of salivary ducts.

Differential Diagnosis

- *Traumatic*—short duration and history.
- *Aphthous ulcer*—short duration, painful and heals in 2 to 3 weeks.
- *Squamous cell carcinoma*—rare on palate, older age and biopsy.
- *Syphilis*—painless indurated edema, painless lymph node swelling and serology.
- *Non-Hodgkin's lymphoma*—biopsy.

Management

- *Self limiting*—it is a self-limiting condition. It does not require any treatment. The healing occurs in six to twelve weeks via secondary intention.
- *Debridement*—debridement and saline rinses may aid in the healing process.

Minor Salivary Gland Tumor

Early minor salivary gland tumor is usually nodular or dome, shaped elevation, with smooth contour. Overlying mucosa is normal or appears smooth and glossy, due to tension. After trauma, ulcer appears which is persistent and becomes necrotic. Its occurrence in an posterior aspect of hard palate; next commonly on upper lip, buccal mucosa, retromolar region, tongue and floor of mouth.

There is higher frequency in women with age 30 to 39 for benign and 40 to 49 for malignant tumors.

Mucoepidermoid and adenocarcinoma are common variety. Lung is the common site of distinct metastasis.

Radiologically, it may present well defined saucer like depression of underlying bone in contrast to malignant tumor which invades the bone and produce ragged radiolucent defect.

On sialography, an area of under filling within the gland, due to ductal compression by the tumor is seen. The ducts adjacent to the tumor are usually stretched around this is known as '*ball in hand*' appearance. Retention of contrast media in the displaced ducts during the emptying phase is seen.

Introduction

Paranasal sinuses are the air filled spaces present with some bone around the nasal cavities. The sinuses are frontal, maxillary, sphenoidal and ethmoidal. Because of the close proximity of the maxillary teeth with the maxillary sinuses, these are the most important paranasal sinuses in dental point of view. They are the largest air filled sinuses surrounding the nose.

Development of Maxillary Sinus

- *Formation of maxillary process*—during 4th week of embryonic life, the dorsal portion of the 1st pharyngeal arch forms maxillary process. It extends forwards beneath the developing eye and gives rise to the maxilla, the zygomatic bone and part of the temporal bone.
- *Evagination from primitive ethmoid infundibulum*—the maxillary sinus starts to develop at about 12 weeks as an evagination from the primitive ethmoid infundibulum in the lateral wall of the middle meatus of the corresponding nasal cavity when the nasal epithelium invades the maxillary mesenchyme.
- *Sinus at birth*—at birth, maxilla is filled with deciduous tooth germs which are very close to the orbital floor so the superior dental nerves and vessels have very short distance to travel to reach the teeth.
- *Separation of alveolar and orbital aspect*—the alveolar and orbital aspects of the maxilla gradually become separated by the cancellous bone which is then resorbed as the sinus enlarges.
- *Pneumatization of maxilla*—pneumatization of the maxilla commences just below the orbital floor.
- *Expansion of maxillary sinus*—down growth of the maxillary sinus leaves the ostium in a position

Fig. 27-1: Position of maxillary sinus.

unfavorable for gravitational drainage. The maxillary sinus expands not only downward but also forward and backward from its initial evagination, the site which persists as the antranasal duct. It undergoes concurrent lateral expansion and by the end of the first year, extends beneath the orbit as far as the infraorbital canal (Fig. 27-1).

- *Sinus at the end of 2nd year*—by the end of 2nd year, the sinus has reached about half to its adult size.
- *Facial growth*—as the facial growth is continued by surface deposition on the face, alveolar processes and palate, it is accompanied by the resorption of the internal structure of the maxillary sinus.

Anatomy of Maxillary Sinus

It is also called as the 'antrum of Highmore'. They are the paired structures located largely in the body of maxilla and are mirror image of each other. Maxillary antrum contains air and is lined by mucoperiosteum with a pseudostratified ciliated columnar epithelium.

- *Shape*—it is pyramidal in shape with its base directed medially towards the lateral wall of the nose and the apex directed laterally in the zygomatic process of the maxilla.
- *Size*—size is variable, varying up to 3.5 cm in height and 2.5 cm in width and 3.2 cm anteroposteriorly.
- *Hiatus semilunaris*—it opens into the middle meatus of the nose in the lower part of the *hiatus semilunaris*.
- *Roof*—it is formed by the floor of the orbit and is transversed by the infraorbital nerve. The roof is flat and slopes slightly anteriorly and laterally. The most medial part of the roof forms the sloping wall of the maxilloethmoidal sinuses, from which disease may spread to the maxillary sinus. Antral infection may involve infraorbital vessels and nerve and malignant tumors growing in the sinus may involve the orbit.
- *Floor*—it is curved rather than flat and is formed by the alveolar processes of maxilla and lies about 1 cm below the level of the floor of the nose. Roots of upper molars and premolar may ridge the floor or project into it. Floor may be subdivided by incomplete bony septa lying between the roots of the teeth, especially in the posterior part of the sinus. The 1st and 2nd molar's roots are the most commonly present in close proximity with the maxillary sinus followed by the premolars and 3rd molar.
- *Medial wall*—it is bounded by the nasal cavity. Medial wall is generally slightly convex toward the sinus.
- *Posterior wall*—it is related to the pterygopalatine fossa. The posterior wall bulges posteriorly towards the infratemporal fossa.
- *Lateral wall*—it is related to zygoma and cheek.
- *Anterior wall*—it is related to the cheek. It is depressed by canine fossa on the anterior surface of the maxilla and is convex toward the interior of the sinus.
- *Radiological anatomy*—an antrum appears radiographically as a radiolucent cavity in the maxilla, with well defined, dense, corticated radiopaque margins or walls. The internal bony septa and blood vessel canals in the walls all produce their own shadow.
- *Arterial supply*—facial, infraorbital and greater palatine arteries.
- *Venous drainage*—into the facial and pterygoid plexus of veins.
- *Lymphatic drainage*—drains into the submandibular nodes.
- *Nerve supply*—it is supplied by infraorbital and anterior, middle and posterior superior alveolar nerves.

Function of Maxillary Sinus

- *Reduction of weight of the facial skeleton*—as the maxillary sinus is filled with air rather than cancellous bone, lightens the face by approximately the weight of a pair of spectacles.
- *Phonetic resonance and auditory feedback*—the sinuses may act as a resonating box for the singing voice. The sinuses also affect the conductance of the voice to one's ear.
- *Insulation*—the sinuses may insulate the orbits from intranasal temperature variations.
- *Air conditioning*—the maxillary sinus contain some serous gland whose watery secretion evaporates to humidify the contained air.
- *Water conservation*—the sinuses may act as accessory heat exchanges, warming inspired air to increase its moisture content.
- *Olfaction*—pneumatization may have evolved to increase the area of olfactory mucosa thereby improving the sense of smell.

Examination and Investigation of Maxillary Sinus

- *Clinical examination*
 - *Examination of middle third of face*—the middle third of the face should be inspected for the presence of asymmetry, deformity, swelling, erythema, ecchymosis or hematoma. Epiphora, nasal obstruction, epistaxis or other discharge or odor from the nostril should be noted.
 - *Extraoral palpation*—examination should include palpation of the facial wall of the sinus above the premolar, where the bone is thinnest, either through the soft tissue of the cheek or more directly intraorally.

- *Intraoral examination*—intraoral examination should be performed for alveolar ulceration, expansion, tenderness or paresthesia of the upper molar and premolar region. Palatal ulceration should be biopsied if there is no obvious cause and it does not heal within 1 week.
- *Rhinascopy*—a nasal speculum and headlight or mirrors are necessary for proper examination of the nasal passage. A topical vasoconstrictor may decrease the size of a large inferior turbinate which obstruct the view of the middle turbinate and middle meatus. When the middle meatus is exposed, the hiatus semilunaris and bulla ethmoidalis are seen anteriorly and it is possible to cannulate or probe the ostium more posteriorly. Pus may be seen in middle meatus.
- *Nasendoscopy*—under local anesthesia, the nasal opening of the maxillary sinus in the middle meatus may be examined thoroughly using a narrow fiberoptic endoscope. It is important as sinus diseases usually start in the middle meatus.
- *Transillumination*—it is performed in the darkened room by insertion of an electrically safe bright light into the mouth (with the lip closed) after removal of maxillary prosthesis. A difference in luminosity between two sinuses which are seen best at the medial third of the infraorbital rim indicates the presence of unilateral disease. A large cyst filled with clear fluid will be opaque on radiograph but brilliantly clear on transillumination. Good transillumination indicates presence of air in the sinus while failure of transillumination indicates presence of pus, solid lesion or mucosal thickening.
- *Bacteriology and cytology*—proof puncture of the antrum is usually performed through the inferior meatus to confirm radiological appearances. After topical application of vasoconstrictor and analgesic spray, a 'trocar and cannula' is passed under the attachment of the inferior turbinate up to the genu where it will naturally rest. The body of trocar is held in the palm of the hand with the index finger running along its haft to provide control and a stop. It is directed towards the tragus of the ipsilateral ear while the patient's head is held still. Moderate pressure with a rotary movement will lead to perforation of the thinnest part of the lateral inferior meatal wall, which is just behind the lacrimal duct orifice. Trocar and cannula is advanced to the lateral sinus wall and then withdrawn several millimeters before the trocar is removed. An aspirate is withdrawn into an empty syringe and sent for bacteriological and cytological examination.
- *Fiberoptic antroscopy*—in this, sinuses unresponsive to treatment or any suspicious areas which is seen radiographically, can be examined by direct vision through an endoscope. It can be performed under local

anesthesia as an outpatient procedure. The antrum is entered using a sharp trocar and cannula which can be pushed directly through the anesthetized oral or nasal mucosa, bone and sinus mucosa into the antrum. The trocar is then removed and the endoscope is inserted along the cannula and attached to a light source. It is mainly used in orbital blowout fracture where clinical and radiological examination is inconclusive.

• *Radiography:*

- *Periapical*—it will show the floor, the base of antral cavity and relationship with upper posterior teeth.
- *Caldwell posteroanterior*—good visualization of frontal sinus and ethmoidal air cells, nasal cavity and superior portion of the maxillary antrum.
- *Water's view*—visualization of maxillary sinus, when the mouth is open; sphenoid sinus can also be seen. It usually shows the roof or upper borders, medial wall and allows comparison of both maxillary sinuses.
- *Lateral skull view*—examination of sphenoid and maxillary sinuses especially anterior and posterior walls.
- *Submentovertex*—to define extent of the sphenoid sinus.
- *Computed tomography*—delineation of soft tissues in the sinus. It allows comparisons of the two sides (Fig. 27-2) of maxillary sinus.

Fig. 27-2: CT scan showing maxillary sinus.

- *Scintigraphy*—radioactive isotopes are used diagnostically to demonstrate physiological changes in tissue that often precede anatomical changes or therapeutically to destroy tumor cells. Extension of antral carcinoma to involve bone produces an osteoblastic

response ahead of the advancing malignant bone destruction. This is evident in the delayed phase of a radionuclide bone scan as bone destruction becomes visible on the radiograph.

- **Ultrasound**—bony wall of the sinus is so thin that high power, short duration sound waves from a transmitter are able to pass through it. They are reflected back to the receiver when they hit an impenetrable object. It is effective in distinguishing normal sinuses, chronically inflamed sinus lining and if sinus is filled with fluid, tumor or scar.
- **Magnetic resonance imaging**—MRI is extremely sensitive in demonstrating maxillary antrum pathology due to the high signal intensity on T₂-weighted image of almost soft tissue abnormalities, contrasted with the absence of signal from both air within the sinus and the surrounding cortical bone.

Classification of Maxillary Sinus Disorders

It is described in Tables 27-1 to 27-3.

Table 27-1: First classification

A. Traumatic	
• Fracture of maxilla, nasal bone, zygoma and orbital floor • Hematoma • Foreign bodies—root piece, bullet injury, antroliths • Oroantral fistula	
B. Inflammatory	
• Acute and chronic sinusitis • Local hyperplasia from odontogenic infection • Antral polyp • Osteomyelitis	
C. Cysts	
<i>Intrinsic</i>	<i>Extrinsic</i>
• Mucus retention cyst • Serous cyst • Pseudocyst	• Odontogenic • Radicular • Dentigerous • Primordial • Keratocyst • Non-odontogenic • Globulomaxillary • Traumatic • Aneurysmal bone cyst (ABC)
D. Neoplasms	
<i>Odontogenic</i>	
• Ameloblastoma • Adenoameloblastoma • Calcifying Epithelial Odontogenic Tumor (CEOT)	
<i>Non-odontogenic</i>	
• Exostosis • Enostosis	
<i>Malignant</i>	
• Squamous cell carcinoma • Midline lethal granuloma	
E. Metabolic	
• Fibrous dysplasia • Leontiasis ossea	

Table 27-2: Second classification

A. Infection/Inflammation	
• Acute sinusitis • Chronic sinusitis	
B. Trauma	
• Oro-antral communication • Fracture of the maxillofacial skeleton • Foreign bodies within the antrum	
C. Cysts	
• Intrinsic • Extrinsic	
D. Tumors	
• Intrinsic • Extrinsic	
E. Others bone abnormalities	
• Fibrous dysplasia • Paget's disease • Osteopetrosis	

Table 27-3: Third classification

Developmental	
• Crouzon syndrome • Treacher Collins syndrome • Binder syndrome	
Inflammatory	
• Mucositis • Maxillary sinusitis • Empyema	
Cyst	
<i>Non-dental</i>	
• Benign mucosal cyst of maxillary antrum • Mucocele • Surgical ciliated cyst	
<i>Dental</i>	
• Radicular cyst • Dentigerous cyst • Globulomaxillary cyst • Odontogenic keratocyst	
<i>Benign tumor</i>	
• Antral polyp • Antral papilloma • Osteoma • Ameloblastoma	
<i>Malignant tumor</i>	
• Squamous cell carcinoma • Invasion of the maxillary sinus by local malignant disease • Metastatic carcinoma of the maxillary sinus	
<i>Traumatic</i>	
• Fractured root • Sinus contusion • Blowout fracture • Isolated injury • Complex fracture • Oroantral fistula • Foreign bodies	
<i>Calcification</i>	
• Antroliths	
<i>Miscellaneous</i>	
• Fibrous dysplasia • Pseudotumor	

Developmental Disorders

- *Crouzon syndrome*—early synostosis of the sutures produce hypoplasia of the maxillae and therefore the maxillary sinus, together with the high arched palate.
- *Treacher Collins syndrome*—Mandibulofacial dysostosis is associated with grossly and symmetrically underdeveloped maxillary sinuses and malar bones.
- *Binder syndrome*—maxillonasal dysplasia (Binder syndrome) involves hypoplasia of the middle third of the face. There is maxillary retrognathism, smaller maxillary length and frontal and maxillary sinus hypoplasia.

Inflammatory Disorders

They are caused by chemical irritation, introduction of foreign body, facial trauma, etc.

Mucositis

It is the name given when there is thickened mucous membrane of maxillary sinus. Normally, mucous membrane of maxillary sinus is about 1 mm in thickness. When the lining mucosa becomes inflamed from either infection or an allergic process, it may increase in thickness by about 10 to 15 times. This inflammation is called as *mucositis*.

Causes

- *Inflammatory disease*—dental inflammatory lesion such as periodontal disease or periapical disease may cause localized mucositis.

Clinical Features

It is usually asymptomatic and it is discovered on routine radiograph.

Radiological Features

- *Appearance*—image is detected on a radiograph as a band, noticeable more radiopaque than the air filled sinus and paralleling the bony wall of the sinus.
- *Size*—mucosal thickening can vary from a few millimeters to a thick, hypertrophic, redundant mucosa (**Fig. 27-3**).

Diagnosis

- *Clinical diagnosis*—not possible to make clinical diagnosis.
- *Radiological diagnosis*—parallel radiopaque band seen in the wall of sinus will diagnose this lesion.

Management

- *Removal of cause*—it will disappear after removing the cause.

Fig. 27-3: CT coronal section showing fine mucosal thickening, involving medial and lateral wall along with the floor of the maxillary sinus bilaterally (Courtesy Dr Ashok L).

Maxillary Sinusitis

Inflammation of the mucosa of the paranasal sinuses is referred to as *sinusitis*. When maxillary sinus is involved, it is called as *maxillary sinusitis*. When all the sinuses are involved, it is called as *pansinusitis*.

Types (depending upon duration)

- *Acute*—This type is associated with severe pain in sinus area.
- *Subacute*—it is an interim stage between acute and chronic sinusitis.
- *Chronic*—it develops as a result of neglected and overlooked dental focus of infection. The lining becomes thicker and irregular.

Etiology

Dental causes

- *Periapical infection from the teeth*—it may follow dental infection particularly from upper molar and premolar teeth. The anatomic proximity of the roots of the maxillary bicuspid and molar teeth to the floor of the sinus leads to potential infection of the sinus by direct extension of an apical abscess.
- *Oroantral fistula*—the accidental opening in the floor of the maxillary sinus during dental extraction is called as oroantral opening.

- *Periodontitis*—it may spread from a deep pocket of marginal periodontitis.
- *Traumatic*—injury of facial bones especially nasal bones and malar bones.
- *Dental material in the antrum*—perforation of endodontic filling substance. If root canal is overfilled then there are more chances of gutta purcha point to be inserted into the maxillary sinus.
- *Implant*—implants are used in the upper edentulous jaw to aid the retention of dentures or bridges or replace missing teeth. Implants are also used when there is insufficiency of bone to support the denture. In these cases as bone is thin, implant can penetrate the nose or sinus.
- *Infected dental cyst*—cysts which have become infected and involve the maxillary sinus can also cause sinusitis.

Non-dental causes

- *Mechanical obstruction of ostium*
 - *Common cold*—it is the most common cause of mechanical obstruction of ostium. It will produce inflammatory edema of the nasal mucosa which obstruct the antronasal duct and cause mucus to accumulate in the sinus. Trapped mucus becomes secondarily infected by local commensal bacteria.
 - *Allergic rhinitis*—it may cause maxillary discomfort due to edema round the ostium and retention of secretion.
 - *Other conditions*—deviated nasal septum, presence of nasal polyp and prolonged nasotracheal intubation can cause stagnation and relative anaerobiasis.
 - *Direct bacterial contamination*—infected material may also be introduced directly by jumping or hydroskiding feet first into contaminated water without holding the nose or during diving, when pressure changes in the nose force nasal secretion into the sinus.
 - *Immune deficiency*—sinusitis can occur in immune deficiency state, like leukemia, lymphoma and AIDS.
 - *Influenza*—it can also occur in influenza when bacteria invade as secondary microorganisms.
 - *Blood borne infection*—it can also occur in some cases of blood borne infection.
 - *Disease of maxillary sinus*—benign mucosal cyst or tumors of the maxillary sinus can also lead to maxillary sinusitis.
- increased by biting on the affected side but unaffected by drinking hot, cold or sweet fluids. Pain may be referred to various areas including the teeth, orbit, head and ear. Pain in the teeth may be referred to the premolars and molars on the affected side. Teeth in the involved side become sore and painful.
- *Postnasal drip*—postnasal drip may cause irritation, stuffiness and nasal discharge. Due to this, patient may get difficulty in breathing.
 - *Generalized toxemia*—generalized toxemia develops, i.e. fever with chills, dizziness, malaise and nausea.
 - *Nasal discharge*—nasal discharge is watery in the beginning but later becomes mucopurulent. In cases of sinusitis from infected teeth, the discharge has a foul odor.
 - *Nasal mucosa*—the nasal mucosa of the anterior nares may show reddening and inflammation and there may be presence of pus.
 - *Tenderness on palpation*—tenderness to pressure or swelling over the involved sinus. Since the anterolateral and posterolateral sinus walls are thinnest in the area above the tooth root, thumb pressure on the cheek region is the best way to elicit tenderness externally. Premolar and molars of the affected side may be sensitive to percussion.
 - *Intraoral finding*—intraorally, there may be a mucobuccal swelling, reddening and pain near the sinus region.
 - *Postural test*—if no pus is seen in the middle meatus, it is decongested with a pledge of cotton soaked with a vasoconstrictor and patient is made to sit with the affected sinus turned up. Examination after 10-15 minutes may show discharge in the middle meatus.
 - *Complication*—the most common complication is spread of infection to the orbit. Orbital swelling, pain and loss of vision can also occur.

Subacute

- *Symptoms*—It is devoid of symptoms associated with acute congestion such as pain and generalized toxemia.
- *Discharge*—discharge is usually purulent and associated with a nasal voice and stuffiness.
- *Soreness*—soreness of throat is common feature.
- *Disturbed sleep*—patient can not sleep well due to cough that irritates the patient constantly.

Chronic

- *Symptoms*—general symptoms of chronic sinusitis include sense of tiredness, low grade fever and feeling of being unwell. Stuffy sensation over the affected side of the face.
- *Other features*—there is nasal obstruction, nasal discharge and headache are the related symptoms.

Clinical Features

Acute maxillary sinusitis

- *Symptoms*—the main symptom is severe pain which is constant and localized. Pain may be felt in the area of eyeball, cheek and frontal region. Pain may be exacerbated by stooping or lowering the head. Pain is

Radiographic Features

- **Radiodensity**—radiographically, the thickening of the mucous membrane and the accumulation of secretions that accompany sinusitis reduce the air content and it will appear as radiopaque (Fig. 27-4).

Fig. 27-4: Opacification seen in right maxillary sinus due to sinusitis (Courtesy Dr Ashok L).

- **Four patterns are seen:**
 - **Localized thickening**—localized thickening at the base of the sinus.
 - **Generalized thickening**—roughly generalized thickening of mucoperiosteum around the entire wall of the sinus.
 - **Complete filling except ostium**—complete filling of the sinus except in the region of the ostium on the medial wall.
 - **Complete filling**—complete filling of the sinus.
- **Allergic sinusitis**—in the cases of allergy, mucosa will be more lobulated in contrast to that in infection where it is straighter and parallel to the sinus wall.
- **Chronic sinusitis**—chronic sinusitis may result in persistent opacification of the sinus and sclerosis or thickening of surrounding bone.
- **Antral halo appearance**—Sometimes if infected teeth are involved then inflammatory changes may lead to resorption of the antral floor and remodeling to produce the appearance described as an antral halo.
- **Resolution of sinusitis**—resolution of acute sinusitis will appear as small clear areas appear in the interior of the sinus as the thickened mucosa gradually shrinks.

Diagnosis

- **Transillumination test**—affected sinus will be found opaque.
- **Radiograph**—Water's view (Fig. 27-5) and OPG can be taken.

Fig. 27-5: Water's view showing complete opacification of left maxillary sinus (Courtesy Dr Ashok L).

- **Laboratory diagnosis**—there is elevated leukocyte count. Lining of maxillary sinus may show a typical acute inflammatory infiltrate with edema of the connective tissue and often hemorrhage. In chronic cases, cellular proliferation is present.

Management

- **Removal of the cause of dental infection**—treatment should be directed to drain the periapical abscess from the root canal or by extracting the teeth.
- **Antibiotic**—most commonly used antibiotic is doxycycline hydrochloride. Doxycycline is given in the dose of 100 mg daily. Penicillin is also the drug of choice as it is effective against most of the anaerobic microorganisms. In some cases, amoxicillin or clotrimazole can be given.
- **Analgesic and anti-inflammatory drugs**—these drug are used to control pain and inflammation. Most commonly used are Ibuprofen or Nimesulide.
- **Nasal decongestant**—Ephedrine nasal drops (0.5%) are most commonly used and give relief for several hours. Xylometazoline (0.1%) is the alternative drugs to Ephedrine but it can lead to more rebound effect.

- *Stem inhalation*—it may act by hydrating the mucous layer, making it less viscous and thereby encouraging normal ciliary clearance of the maxillary sinus. The use of volatile aromatic additive, such as menthol or eucalyptus can be used to stimulate cold receptor nerve endings.
- *Antral lavage*—if antibiotics and nasal drops fail to resolve the condition, pus may be removed from the antrum. This procedure is carried out under local anesthesia by inserting hollow trochar and cannula into the antrum through the nasal wall beneath the inferior turbinate. Warmed saline is syringed through the cannula so that the fluid and pus return via the antranasal duct.
- *Antrostomy*—if all the above procedures fail to cure the sinusitis and infection is recurrent then inferior meatal antrostomy and middle meatal antrostomy can be done.
- *Transnasal endoscopic surgery*—endoscopic approach is made to the middle meatus using rigid instrument to visualize the infundibulum and the natural opening of the sinuses.

Cysts

Cysts are classified into dental and nondental.

Nondental Cyst

Nondental cysts of maxillary sinus are as follows.

Antral Pseudocyst or Benign Mucosal Cyst of Maxillary Antrum

It is also called as, '*retention cyst*', '*pseudocyst*', '*lymphangiectatic cyst*', '*false cyst*', '*benign mucosal antral cyst*', '*serous non-secretory retention pseudocyst*', '*mesothelial cyst*' and '*intramural cyst*'.

Pathogenesis

- *Inflammatory exudate*—severe inflammation around the ducts of mucus glands of the antral lining may alter their integrity. When the patient sneezes, mucus can be expelled into soft tissue through the wall of such injured duct. Once the pathway for extraglandular accumulation of mucus has been established, the process may continue until a cyst has developed. Infection may result from odontogenic source or it may cause due to allergy.
- *Mechanical factors*—because of frequent location of the lesion at the sharp angle between the floor and frontal or lateral aspect of the sinus cavity close to the alveolar process mechanical factors might be involved in the development of cyst. Mucosal swelling, perhaps the result of a previous common cold may lead to mechanical stress leading to the rupture of sharp angle tissue or its bony attachment.
- *Proteolytic process*—some have also found a low concentration of alpha-antitrypsin in the cystic fluid which suggests the possibility that a proteolytic process could lead to the expansion of the cyst.

Clinical Features

- *Age and sex*—the great majority of cases were found in patients in the age group of 21-30 years. Males are more commonly affected than females in the ratio of 2:1.
- *Sites*—most commonly involved sites are the antral floor and the lateral wall of maxillary sinus.
- *Symptoms*—there may be localized dull pain in the antral region, or fullness and numbness of the cheek. If it is completely filled sinus, it will prolapse through the ostium and cause obstruction and postnasal drip. There may be pain in the teeth and face over or near the sinus. There may be stuffiness, fullness, headache, symptoms of cold, and numbness of upper lip.
- *Signs*—sometimes, antral swelling may also occur. There is copious discharge of yellow fluid from the nostrils. Retention of pseudocyst may enlarge and fill the sinus cavity completely, it frequently ruptures as a result of abrupt pressure change caused by sneezing or blowing the nose. Expanding cyst will cause herniation through the ostium into the nasal cavity where it subsequently ruptures.

Radiological Features

- *Radiodensity*—it is homogenous mass that is more radiopaque than the surrounding sinus cavity.
- *Appearance*—It appears as a soft tissue mass rather than a calcified area so that medial and lateral landmarks can generally be visualized through the lesion.
- *Site*—It is found projecting from the floor of the sinus, although some may form on the lateral walls.
- *Shape*—the cyst appears as a spherical, ovoid or dome shaped radiopacity (**Fig. 27-6**).
- *Margins*—it has a smooth and uniform outline. The smooth curved borders are well defined but not well corticated.
- *Base*—they may have a narrow or broad base.
- *Size*—they vary in size from minute to very large and may occasionally occupy the entire maxillary sinus. Image may be of a fingertip to that of a completely filled sinus making it opaque.
- *Bone*—there is no resorption of adjacent bone and of particular importance is the persistence of thin radiopaque line of the antral cortex.

Fig. 27-6: Dome shaped radiolucency seen in left maxillary sinus suggestive of antral pseudocyst.

- Mucus type is associated with thickened mucosa while serous type appears normal.

Diagnosis

- *Clinical diagnosis*—dull pain in antral area, discharge of yellow fluid from nostril should suspect this cyst.
- *Radiological diagnosis*—ovoid and dome shaped radiopacity projecting from the floor will diagnose this condition.
- *Laboratory diagnosis*—biopsy shows infiltration of chronic inflammatory cells in connective tissue wall of the cyst. Cystic fluid is thick, tenacious, white translucent and sterile.

Differential Diagnosis

- *Inflammatory lesions of the sinus*—in inflammatory lesions, patient may complain of pain which is absent in case of cyst.
- *Apical radicular cyst*—tooth is not vital.
- *Odontogenic cyst*—mucus retention cyst is dome shaped and does not have thin marginal line representing the hyperostotic borders characterized by odontogenic cyst. Odontogenic cysts are more rounded and tear shaped and most are not so homogenous, as mucus retention cyst. Lamina dura is not intact in odontogenic cysts.
- *Antral polyp*—they are more opaque, more heterogeneous and multiple commonly associated with thickened mucosa.
- *Surgical ciliated cyst*—more rounded and more radiolucent.

- *Neoplasm*—the neoplasm is less likely to be dome shaped as the retention cyst.

Management

- *Removal of foci of infection*—the adjacent tooth should be treated for any source of infection.
- *Caldwell-Luc operation*—large cysts should be removed through Caldwell-Luc operation.

Sinus Mucocele

It is an expanding destructive lesion that begins with the development of mucus retention cyst in a blocked ostium. If mucocele becomes infected, it is called as pyocele or mucopyocele.

Etiopathogenesis

- *Obstruction of sinus ostium*—blockage or obstruction may result from long and tortuous infundibulum, intranasal or intra-antral inflammation, and from polyps and bony neoplasm. This blocked ostium will act as separate cyst like structure lined by epithelium and filled with mucin.
- *Accumulation of mucin*—the cystic lesion continues to accumulate mucus. After it has filled the sinus cavity the pressure increases and the lesion will become destructive by expanding and destroying sinus wall by thinning out the bone wall.

Clinical Features

- *Site*—there is predilection for ethmoid and frontal sinuses due to the relative difficulty as a cyst has protruding through the longer and narrower nasofrontal duct and infundibulum into the nasal cavity, in contrast to the shorter and larger ostium in case of maxillary and sphenoidal sinuses.
- *Symptoms*—it may exert pressure on the superior alveolar nerve in the resorbing sinus wall and cause radiating pain. Sensation of fullness in the cheek may be accompanied swelling over the anteroinferior aspect of the antrum, the area where the wall is thinnest. If the cyst expands inferiorly, it may cause loosening of the posterior teeth in that area. If it expands medially, lateral wall of the nasal cavity is deformed and nasal airway is obstructed.
- *Signs*—if expands towards the orbit, it may cause diplopia and proptosis (protrusion of the globe of the eye).

Radiographic Features

- *Site*—about 90% of the cases are in ethmoidal and frontal sinuses and are rare in maxillary and sphenoid sinuses.

- **Radiodensity**—there is opacification of sinus.
- **Shape**—the shape of the sinus is changed into a more circular shape as the mucocele grows.
- **Effect on surrounding structures**—the shape of sinus changes with bony expansion. There is erosion of septa and the bony wall may occur. Borders of the expanding sinus become sclerotic.
- **Frontal sinus**—scalloped borders of frontal sinus become smooth by erosion and intersinus septum may be displaced.
- **Maxillary sinus**—teeth may be displaced or resorbed.
- **Ethmoid sinus**—displacement of the lamina papyracea may occur, displacing the content of the orbit.
- **Sphenoid sinus**—the expansion may be in a superior direction, suggesting a pituitary neoplasm.
- **Orbit**—Bone of supramedial border of the orbit is destroyed or displaced.

Diagnosis

- **Clinical diagnosis**—symptoms of sinus mucocele are severe and consist of radiating pain, diplopia and obstruction of nasal airway.
- **Radiological diagnosis**—opacification of sinus with erosion of septa. Displacement of teeth can also occur.

Differential Diagnosis

- **Malignancy**—any suggestion of a lesion associated with occluded ostium should be mucocele.

Management

- **Surgical**—surgical removal by the Caldwell-Luc operation is traditional method for management of sinus mucocele.
- **Endoscopic middle meatal antrostomy**—nowadays, this treatment module gives good results.

Postoperative Maxillary Cyst

This is also type of sinus mucocele which occurs after trauma. It is also called as '*surgical ciliated cyst of maxilla*'. Its name arises from the fact that it has a delayed complication arising within years after surgery involving the maxilla.

Pathogenesis

- **Trapping of epithelium in wound closure**—they are derived from the epithelial lining of the maxillary sinus which is trapped in the wound during closure of the Caldwell-Luc incision and subsequently begins to proliferate. Sinus lining will separate from the sinus and epithelium lined cavity is formed in which mucin is secreted. This type of cyst is originated after difficult extraction in which sinus lining is damaged.

Clinical Features

- **Age and sex distribution**—the great majority of the patients are in the fourth and fifth decades and their age ranges from 21 to 72 years. There is a preponderance of males to females (2:1).
- **Symptoms**—pain, discomfort or swelling in the cheek or face or intraorally in the palate or alveolus is a common complaint.
- **Sign**—pus may be discharged.

Radiological Features

- **Site**—well defined radiolucency closely related to the maxillary sinus.
- **Margin**—surrounding bone sclerosis is evident in at least a part of the bony margin. There is pneumatization and relatively well defined unilocular radiolucent margins showing marked osteosclerotic changes.
- **Pressure effect**—occasionally, cyst appears to encroach on the sinus itself but lack of communication between the two has been demonstrated by injecting the sinus with a radio-opaque material. As the lesion enlarges, sinus walls become thinned and eventually perforate and may resemble a malignant neoplasm. Resorption of maxillary alveolar processes also occurs.

Diagnosis

- **Clinical diagnosis**—history of trauma or operation followed by pain and discomfort in the sinus region.
- **Radiological features**—contrast study will help to diagnose this cyst. Well defined radiolucency close to sinus will give clue to diagnose the case.
- **Laboratory diagnosis**—cysts are lined by pseudo-stratified columnar epithelium with squamous metaplasia in chronically inflamed cases. Combination of ciliated, cuboidal and squamous epithelium with varying numbers of mucus cells may be seen.

Management

- **Enucleation**—enucleation through an approach appropriate to the site is the treatment of choice. Recurrence may occur if the wall is very thin and there is perforation of the bone making enucleation difficult.

Dental Cyst

These are described in detail in Chapter 13: Cysts of Jaw.

- **Radicular**—those that develop in the maxilla may extend into the maxillary sinus. They may cause elevation of the floor of the sinus resulting in a halo appearance. Large cysts may obliterate the sinus and make differentiation of this form from sinusitis is difficult.

- *Dentigerous cyst*—when they expand into the sinus, the radiograph shows radiolucency elevating an intact wall or floor of the maxillary sinus. If it is small, it is usually round, dome shaped opacity in the base of the antrum with well defined radiopaque corticated margins to the edge of the meniscus. Sometimes, there may be displacement of the associated tooth (**Fig. 27-7**). If the cyst is large then there is total opacity of the antral region due to complete compression of the antral cavity. There is also a loss of antral outline.
- *Cyst in the globulomaxillary area*—they may expand so as to obliterate or alter the typical pattern or border of nasal fossa and anterior process of the maxillary sinus.

Fig. 27-7: Dentigerous cyst involving maxillary sinus. Note the displacement of the tooth in the sinus.

Benign Tumor

Antral Polyp

The thickened mucosa of chronically inflamed sinus frequently form irregular folds called as '*polyps*'. Polypoid atrophy of mucosa may develop into an isolated area or number of areas throughout the sinus.

Clinical Features

- *Age*—it usually occurs in young persons.
- *Site*—maxillary sinus is more involved as compared to other sinus. In maxillary sinus they may arise from any part of the sinus wall and occasionally pass through the ostium to appear in the nose as antrochoanal polyps.
- *Symptoms*—patients present with nasal obstruction, pain is very mild on pressure as mass present inside the nose.
- *Saints triad*—it is associated with "Saints triad", i.e. nasal and antral polyposis, aspirin sensitivity and asthma.
- *Exacerbation of asthma*—polyps may exacerbate the asthma by causing obstruction of the nose. It is most commonly pedunculated, or sessile mass which grows very slowly. After the polyp grows to occupy most of the antrum it frequently herniates into the nasal cavity. This may be brought about by repeated sneezing or nose blowing in about 4-6% cases.

Radiological Features

- *Appearance*—it appears as homogenous soft masses with smooth, outwardly convex borders. Single or multiple lesions may be present. If polyp occurs in the roof of the maxillary sinus in a patient with a history of trauma, the plain film examination may simulate a blow out fracture.
- *Destruction of walls of sinus*—Polyps may cause destruction or displacement of bone. They can displace or destroy medial or lateral wall.
- *CT features*—have mucoid attenuation with mucosal enhancement seen at the polyps' surface. It appears as smooth homogenous mass.
- *MRI features*—polyps will have low to intermediate T₁-weighted and high T₂-weighted signal intensities. Mucosa adjacent to polyps will enhance as compared (**Fig. 27-8**) to polyps.

Fig. 27-8: MRI T₂ coronal section image showing well margined hyperintense area in the floor of the right maxillary sinus (Arrow mark) suggestive of solitary polyp (Courtesy Dr Ashok L).

Fig. 27-9: Polyp seen in left maxillary sinus as homogenous radiopacity (Courtesy Dr Bhaskar Patle).

Diagnosis

- *Clinical diagnosis*—saint tried with pain and pressure inside the nasal cavity may give clue to the diagnosis.
- *Radiological diagnosis*—CT and MRI will diagnose the polyp as homogenous radiopaque mass in the sinus (Fig. 27-9).

Management

- *Excision*—simple excision is close with endoscopic surgery or Caldwell-Luc operation.

Antral Papilloma

It is a rare tumor of respiratory epithelium that occurs in the nasal cavity and the paranasal sinuses.

Clinical Features

- *Age and sex*—it is seen in the age group of 20 to 25 years with predominance in males.
- *Site*—usually ethmoid and maxillary sinuses are involved.
- *Symptoms*—there is unilateral nasal obstruction, nasal discharge, pain and epistaxis can occur. Recurring sinusitis and subsequent nasal obstruction on the same side.
- *Appearance*—it has got warty appearance.

Radiographic Features

- *Site*—it appears as isolated polyps in the nose and sinus.
- *Radiodensity*—the neoplasm appears a homogenous radiopaque mass of soft tissue density (Fig. 27-10).
- *Pressure effect*—bone destruction can occur due to pressure erosion.

Diagnosis

- *Clinical diagnosis*—warty appearance with recurring sinusitis may suspect this disease.

Fig. 27-10: Homogeneous radiopaque mass with destruction of wall of right maxillary sinus seen due to papilloma.

- *Radiological diagnosis*—homogenous mass with bone destruction will give clue to the diagnosis.

Management

- *Excision*—surgical excision of tumor should be carried out.

Osteoma

It is most common mesenchymal neoplasm in the paranasal sinus.

Clinical Features

- *Age and sex*—it is more common in 2nd, 3rd and 4th decade. It is more common in male as compared to females and the ratio is 2:1.
- *Symptoms*—it is slow growing and asymptomatic. When symptoms occur, they are as a result of obstruction of the sinus ostium or infundibulum or are secondary to erosion or deformity, orbital involvement or intracranial extension. It may extend in the nose and cause nasal obstruction or swelling on the side of the cheek.
- *Signs*—it may expand into the sinus and produce swelling of the cheek or hard palate. In cases of extension to orbit the patient may have proptosis.

Radiological Features

- *Site*—they occur more often in frontal and ethmoidal sinuses. The maxillary sinuses are also involved.
- *Shape*—lobulated or rounded homogenous masses of high density are seen.
- *Margins*—they have sharply defined margins.

Diagnosis

- *Clinical diagnosis*—nasal obstruction, proptosis may give some clue to the diagnosis.

- *Radiological features*—lobulated homogenous mass of high density is present.

Management

- *Excision*—this tumor should be surgically removed.

Ameloblastoma

It is most common extrinsic tumor affecting the maxillary sinus. It may cause loosening of teeth, nasal obstruction and painless facial deformity. Sinus cavity is invaded at an early stage. There is radiographic appearance equivalent to soft tissue density. Antral cavity is expanded and filled with soft tissue mass. Bony wall is eroded.

Malignant Tumor

Squamous Cell Carcinoma

It originates from metaplastic epithelium of the sinus mucous membrane lining. It is the most common primary tumor of paranasal sinuses comprising 80 to 90% of cancers in this site.

Etiology

- *Idiopathic*—Most cases of squamous cell carcinoma of maxillary sinus are without any cause.
- *Sinusitis*—respiratory epithelium is known to undergo squamous metaplasia in the presence of infection and chronic sinusitis can be predisposing factor for antral carcinoma.
- *Snuff and smoke*—the use of indigenous snuff and the smoky atmosphere may be causal factor for carcinoma of paranasal sinus.
- *Occupational hazards*—it is more common in boot and shoe and nickel worker. Adenocarcinoma of the nasal passage is an occupational hazard for furniture workers.

Clinical Features

- *Age and sex*—mean age of occurrence is 60 years. Males are commonly affected more than females in the ratio of 2:1.
- *Symptoms*—there is facial pain, swelling, nasal obstruction. Patient also complains unilateral nasal stiffness. When the second division of trigeminal nerve is involved, there is intense pain or paresthesia of midface occurs.
- *Signs*—there is ulceration or mass seen on the hard palate (Fig. 27-11).
- *Lymph nodes*—lymphadenopathy is always present in carcinoma of maxillary sinus.
- *Medial wall involvement*—medial wall involvement leads to nasal obstruction, discharge, bleeding and pain.

Fig. 27-11: Ulceration seen on first molar area due to maxillary sinus malignancy.

Epiphora will result if the lacrimal sac or nasolacrimal duct is obstructed.

- *Floor involvement*—involvement of the floor of the sinus leads to expansion of the alveolus, unexplained pain, numbness of teeth, loosening of teeth and swelling of the palate or alveolar ridge and malfitting dentures. It may erode the floor and penetrate the oral cavity (Fig. 27-12).
- *Lateral wall involvement*—lateral wall involvement leads to facial and vestibular swelling, pain and hyperesthesia of maxillary teeth (Fig. 27-13).
- *Roof involvement*—roof involvement leads to diplopia, proptosis and pain over the cheek and upper teeth (Fig. 27-14).
- *Posterior wall involvement*—posterior wall involvement leads to painful trismus, obstruction of Eustachian tube causing stuffy ear, referred pain and hyperesthesia over the distribution of second and third division of trigeminal nerve.

Fig. 27-12: Ulceration and perforation seen in hard palate in maxillary sinus malignancy (Courtesy Dr Ashok L).

Fig. 27-13: Swelling in vestibular region occur due to involvement of lateral wall (Courtesy Dr Ashok L).

Fig. 27-14: Involvement of roof causes swelling in infraorbital region.

- *Nerve involvement*—it may involve infraorbital nerve and produces paresthesia of the cheek or erodes blood vessels giving rise to epistaxis. Paresthesia of mandibular nerve can also occur if the tumor invades the cranium.

Radiographic Features

Small early lesion

- *Shape and radiodensity*—non-specific well defined round soft tissue opacity within the antrum (**Fig. 27-15**).
- *Antral wall*—variable destruction of the bony antral wall. Loss of fine linear outline of the lateral wall is a particularly sensitive sign of bone destruction.

Large well established lesion

- *Pressure effect*—destructive outline of the sinus destroying bone and causing irregular bony radiolucency with

Fig. 27-15: Radiopacity seen on right side of maxillary antrum which is obscuring the wall of maxillary sinus.

erosion of the medial wall. There may be destruction of the floor and anterior or posterior walls (**Fig. 27-16**).

Fig. 27-16: Destruction of walls of maxillary sinus seen in malignancy.

- *Teeth*—occasional resorption and displacement of the teeth. There may be bone destruction around the teeth or irregular widening of the periodontal ligament space.
- *Zygomatic arch*—advanced cases involve destruction of the zygomatic arch.
- *Tomography*—on the tomography, there is destruction of the surrounding hard and soft tissue (**Fig. 27-17**).

Diagnosis

- *Clinical and radiological diagnosis*—ulceration in palate with radiopacity in maxillary antrum may suggest maxillary antrum malignancy.

Fig. 27-17: Destruction of walls of maxillary antrum on left side seen in patient of maxillary antrum malignancy (Courtesy Dr Ashok L).

- *Laboratory diagnosis*—biopsy features are suggestive of squamous cell carcinoma.

Management

- *Cytotoxic drugs*—local intra-arterial infusion of cytotoxic drugs may be helpful for pain control.
- *Radiotherapy*—it is the main mode of treatment. A course of high voltage radiotherapy or gamma rays are given.
- *Surgery*—if radiotherapy cannot control the disease upto the expectation, excision of the maxilla should be performed.
- *Reconstruction*—after surgery, sophisticated prosthesis should be constructed.

Invasion of the Maxillary Sinus by Local Malignant Disease

Tumors of the upper jaw spread easily into the sinus. Pleomorphic adenoma arising in palatal minor salivary gland may bulge into the sinus floor and adenoid cystic carcinoma may invade it.

Metastatic Carcinoma of the Maxillary Sinus

It is rare site for the secondary tumor deposits. The most common site for the primary disease is kidney followed by the breast in females and the testicle (seminoma) in males.

Traumatic Injuries to the Paranasal Sinuses

Root in Antrum

- *Cause*—in maxillary posterior teeth, it is possible that fractured root tip may be forced into the maxillary sinus either while extraction or while removing the root tip. Following incomplete extraction of tooth, the apical segment remaining in the socket may be dislodged by injudicious use of elevators.
- *How to differentiate between root in socket and root in sinus*—if root tip is in the socket and superimposed over the sinus, then lamina dura will be intact and if it is in maxillary sinus, lamina dura will be lost.
- *Perforation of sinus*—when root tip is in the sinus and trapped under mucoperiosteum then it will be fixed and it may cause movement when it perforates the sinus.
- *Removal of root tip*—removal of the root tip can be done through the tooth socket or through the canine fossa by Caldwell-Luc approach.

Foreign Bodies

- *Root fragment and teeth*—displaced root fragments or teeth may present in the sinus.
- *Excess root canal filling*—excess root canal filling material forced through the apex of an upper posterior tooth during endodontic treatment.
- *Oroantral communication*—foreign material pushed into the antrum through an existing oroantral communication.
- *Metallic object*—metallic object such as pellets, bullets and fragments of shells or bombs.
- *Radiological detection*—the presence, position and often the nature of the foreign body can be seen by using the radiograph (**Fig. 27-18**). When roots are present in the socket, it usually reveals root canal but in some cases, there is only root tip present with no root canal seen. If you want to determine it is in the socket or in the sinus then you have to look for the lamina dura and periodontal ligament. If lamina dura and periodontal ligament is present then the root is in the socket.

Sinus Contusion

- *Cause*—blow to the face produces damage to the lining of paranasal sinuses without fracturing the facial bone. Traumatic force can be transmitted through the bony wall and be absorbed by mucosal lining which suffers damage.

Fig. 27-18: Foreign body seen in maxillary sinus.

- *Green stick fracture*—it may cause green stick fracture of the sinus with tearing injury to the mucosal lining.
- *Radiological features*—hazy sinus is produced by edema of the mucosa, soft tissue mass that mimics a retention cyst and as a result of intramucosal hematoma, an opaque sinus or fluid level resulting from hemorrhage on mucosal tear.
- *Difference between sinusitis and sinus contusion*—in sinus contusion, there is bloody nasal discharge, extreme tenderness of involved sinus on pressure, rapid resolution of soft tissue changes.

Blow-out Fracture

- *Cause*—blow-out fracture results from sudden increase in intraorbital pressure due to blow to the eye. The pressure of blow forces the inferior orbital content (fat and muscle) through the fracture.
- *Symptoms*—diplopia (double vision) when victim looks upward (caused by entrapment of inferior rectus) and enophthalmos (backwardly depressed eyelid) following reduction of edema (Fig. 27-19) and fat atrophy.
- *Radiological features*—opacification of sinus with or without a fluid level. Soft tissue mass in upper portion of sinus and image of depressed bone fragment (orbital floor in sinus) (Fig. 27-20). It will produce a tear-drop shaped opacity in the upper part of the antrum, the 'hanging drop appearance' caused by herniation of the

Fig. 27-19: Blow-out fracture showing edema below the eye.

Fig. 27-20: Blow-out fracture seen on the CT.

orbital content downwards into the antrum following collapse of the antral roof. The depression fracture of the orbit is accompanied by fracture of the antrum wall of the maxillary sinus.

Isolated Fracture

It involves single wall, which are identified on the radiograph by a bright line. Anterolateral wall of the maxillary sinus is the most common site. Sometimes fracture of the floor of the maxillary sinus occurs into which roots of the posterior teeth are projecting which occurs during tooth extraction.

Zygomatic Complex Fracture

The fracture occurs at the line of weakness and passes through the orbital floor, usually medial to the zygomaticomaxillary suture and therefore inevitably involves the maxillary sinus. Fractured zygoma is forced into the sinus. It results in tearing of the lining membrane and subsequent bleeding into the antrum. Antrum will appear cloudy or show a fluid level (Fig. 27-21).

Fig. 27-21: Zygomatic complex fracture resulting in the haziness seen in the sinus.

Fractured Tuberosity

Tuberosity fracture inevitably involves the maxillary sinus. It occurs most frequently when extracting a lone standing upper third molar. If the bone is found to be moving with tooth during extraction the operator should stop immediately. Antibiotics, nasal drops and inhalation are therefore prescribed to help and prevent development of a chronic oroantral fistula.

Oroantral Fistula

It is a pathological pathway connecting oral cavity and maxillary sinus. If there is no pathological lining present, it is called as oroantral opening which is seen after tooth extraction.

Causes

- *Extraction of teeth*—teeth which is having periapical infection. Inappropriate or incorrect use of elevators during root or tooth removal may lead to oroantral fistula.

Apices of upper posterior teeth are within 3 mm of the cortical floor of the maxillary sinus or sometimes they may be inside the maxillary sinus. Forceps extraction of a solitary isolated premolar or molar in an edentulous part of the arch is also prone to cause disruption of the sinus floor.

- *Blind instrumentation*—blind instrumentation without adequate surgical exposure, in an attempted retrieval of retained apices in the upper posterior quadrant can cause oroantral fistula.
- *Surgery*—oroantral opening can occur in cases of removal of cysts and benign tumors in upper posterior region.
- *Facial trauma*—oroantral fistula may occurs following massive trauma to the middle third of the facial skeleton, especially if the face is struck by missile or sharp object which is driven through the mouth into the maxillary sinus.
- *Malignant tumor*—malignant tumors of the maxillary sinus may penetrate the lateral bony wall of maxillary sinus or it may erode through the floor of the sinus into the mouth producing oroantral communication.
- *Osteomyelitis*—it is rare, unless there is underlying systemic disease like leukemia, diabetes. A severe osteitis with bone loss could lead to the formation of an oroantral fistula of one or both maxillary sinus.
- *Syphilis*—gummata of the palate may result in a massive oroantral fistula due to destruction of the intervening bone.
- *Inadequate blood clot formation*—inadequate blood clot formation in the alveolus after violation of the maxillary sinus may lead to oroantral communication.
- *Implant denture*—there is destruction of the antral floor in a patient fitted with an implant denture in maxillary region.
- *Malignant granuloma, Wegener's granulomatosis and lymphosarcoma*—when the invasive process spreads to the palate, expansive perforation or ulceration may occur leading to huge fistula.
- *Periodontal problems*—deep periodontal pockets along the side of the upper molar can destroy the bone, which separate the root from the antrum.

Clinical Features

- *Opening*—oroantral opening can be seen immediately after extraction of the tooth.
- *Immediate symptoms*—there is passage of fluid from oral cavity into the nose. Patient also notices inability to blow out cheek and smoke cigarettes. Unilateral epistaxis, due to blood in the maxillary sinus escaping through the nasal ostium is present. There may be escaped of air from the mouth into the nose and an alteration in vocal resonance.

- *Delayed symptoms*—the reason for the delayed response is that, at first instance the oroantral defect was completely occluded by blood clot and it is only when this plug disintegrates as a result of infection than an oroantral communication is firmly established. There may be foul, sweetish, fetid or salty taste in mouth. Facial pain or headache which is of throbbing nature and is exacerbated by movement of the head. There may be painless lump on the gum at the site of extraction socket.
- *Unilateral nasal discharge*—unilateral nasal discharge accompanied by sensation of nasal obstruction or nocturnal coughing resulting from draining of exudate into pharynx.
- *Postnasal drip*—postnasal drip will often lead to an unpleasant taste which is accompanied by nocturnal cough, hoarseness, earache or catarrhal deafness.
- *Acute exacerbation*—inadvertent entry of food particles, chewing gum, fluids, impression materials, dressing and packs may provoke acute exacerbation of the inflammatory disease.
- *Signs of recent fistula*—after forceful extraction, floor of sinus seen with root of the teeth. Sudden disappearance upper molar root while extraction (**Fig. 27-22**). There may be water running out of the nose while rinsing.
- *Signs of established fistula*—a simple dimple on the alveolar ridge may be the only sign. Invasion of antral polyp through fistula resulting in sudden appearance of exophytic mass on the alveolar crest. There is also aspiration of air into mouth through the tooth socket. Tenderness is positive over the maxillary sinus.
- *Sinusitis*—sinusitis occurs with varying intensity depending on diameter of fistula. Patient exhibits swelling and redness covering the sinus and molar eminence as well as pain beneath eye.

Fig. 27-22: Oroantral fistula presented as an opening intraorally (Courtesy Dr Ashok L).

Radiographic Features

- *Break in continuity of maxillary sinus*—radiograph will show break in continuity of maxillary sinus. In some cases there is disalignment of a small portion of the cortical layer of bone.
- *Features of sinusitis*—there are also characteristic features of acute or chronic sinusitis due to ingress of bacteria.
- *Second view should be taken by tilting the head to know location*—evidence of displaced root or tooth and second view of the antrum with the head in a different position may be required to ascertain the exact location of the displaced object.
- *Silver probe examination*—confirmation of presence of fistula can be done by introducing silver probe into the orifice, followed by taking the radiograph.

Diagnosis

- *Clinical diagnosis*—all extracted upper posterior teeth should be examined, not only to ensure they are intact but also for indication of a sinus contamination. If the root is covered with a thin plate of bone or adherent sinus mucosa a communication may be present.
- *Air blow technique*—the patient should be asked to blow air into the pinched nose with the mouth open. This forces the air into the sinus via ostium. If an oroantral opening is present, bubbles appear in the extraction socket.
- *Probing of sinus*—Gentle probing of the socket with a blunt instrument, such as ball ended periodontal probe or small amalgam plugger will confirm the bone defect without perforating an intact lining.
- *Radiological diagnosis*—CT will be able to confirm the diagnosis of oroantral fistula (**Fig. 27-23**).

Management

- *Drug therapy*—antibiotic therapy for 1 week. Most commonly given antibiotics is amoxicillin. Decongestants are given for 1 week.
- *Drainage*—to promote drainage, the oroantral fistula can be enlarged by excising a margin of surrounding mucosa, by cauterizing any granulation tissue and polyps protruding from the sinus with electrocoagulation or simply by cautious application of a chemical agent such as trichloroacetic acid. The patient is provided with a syringe and blunted wide bore needle or a plastic irrigating tube, to wash out the sinus with warm salt water three or four times daily. In some cases, antral lavage and antrostomy is done to help drainage.
- *Prevention from dislodging clot*—if opening is small, great care is to be exercised such as avoidance of use of irrigation, vigorous mouth washing and frequent lusty

Fig. 27-23: Oroantral fistula seen as an opening on the CT scan (Courtesy Dr Ashok L).

blowing of the nose. In majority of the cases, good clot will form and normal healing will occur.

- *Closure of opening*—if large accidental opening is present, its immediate closure can be achieved in the following ways:
 - *Rising of mucoperiosteum*—mucoperiosteum is raised both buccally and palatally and the height of the alveolar ridge is reduced at the site of opening. Edges of soft tissue are freshened up. A periosteal elevator should be used to raise palatal mucoperiosteum so that approximation of mucosal edges is made possible.
 - *Relaxing incision*—relaxing incision is made over the palate avoiding the palatine artery.
 - *Suturing*—flaps are then sutured without tension.
 - *Shrinkage of nasal mucosa*—nasal drops should be given to shrink nasal mucosa and promote drainage.

Calcification

Antroliths

These are calcified masses found in the maxillary sinus. It is defined as a complete or partial calcific encrustation of an antral foreign body, either endogenous or exogenous which serves as nidus. There is calcification of masses of stagnant mucus in site of previous inflammation, root fragments or bone chips or foreign body.

Etiology

- *Endogenous nidus*—endogenous nidus is usually root tip or may be simply fragment of soft tissue, bone, blood or mucus.
- *Exogenous nidus*—exogenous nidus are consisting of snuff or paper.

Clinical Features

- *Age and sex*—it can occur at any age in either sex.
- *Symptoms*—it is usually asymptomatic. But if they continue to grow the patient may complaint of bloodstained nasal discharge, nasal obstruction or facial pain.

Radiographic Features

- *Radiodensity*—they may have a homogenous or heterogeneous density.
- *Internal structure*—there is alternating layer of radiolucency and radiopacity in the form of lamination.
- *Margins*—outline may be ragged or smooth.
- *Shape*—shape may be round (Figs 27-24A and B), oval or irregular and it is attached to the wall of the sinus.

Figs 27-24A and B: Antroliths seen as round shaped radiopacity in the maxillary sinus (Courtesy Dr Ashok L).

Diagnosis

- *Clinical diagnosis*—it is not possible to make confirmed clinical diagnosis.
- *Radiological diagnosis*—round shaped radiopaque structure in the sinus will give clue to the diagnosis.

Differential Diagnosis

- *Root fragments*—pulp canal is seen and it is moved in different direction if head position is changed.

Management

- Removal of antroliths can be done if it is symptomatic.

Traumatic Injury of Soft Tissue

Traumatic Erythematous Macule or Hematoma

Traumatic macule is induced by low grade, usually chronic, physical insult.

Clinical Features

- *Site*—common sites are anterior and lateral border of tongue (**Fig. 28-1**), floor of mouth, posterior palate, buccal mucosa and mucosal surface of lip.
- *Symptoms*—mild to considerable pain and it regresses after the cause is removed.
- *Signs*—it may blanch when digital pressure is used.
- *Size*—size of red zone corresponds closely to size of traumatic agent.
- *Margins*—margins may or may not sharply define.

Fig. 28-1: Traumatic hematoma of the tongue occur due to tongue biting.

Diagnosis

- *Clinical diagnosis*—red lesion with history of trauma may give clue to the diagnosis.

- *Laboratory diagnosis*—inflamed lamina propria covered with thin or eroded stratified squamous epithelium that is completely non-keratinized.

Management

- *Removal of irritant*—mechanical irritant is identified and should be removed.

Ecchymosis and Purpuric Macule (early stage)

It is produced by blunt traumatic insult of sufficient force, on the mucosa of skin to cause superficial extravasation of blood (**Fig. 28-2**).

Fig. 28-2: Soft tissue injury due to trauma.

Clinical Features

- *Site*—palate, buccal mucosa, upper lip (**Fig. 28-3**) and floor of mouth are common site.

- **Size**—size varies according to size and force of physical agent inflicting the damage.
- **Margins**—borders are poorly demarcated and blend imperceptibly with surrounding normal tissue.
- **Signs**—it does not blanch on pressure as RBCs are within the tissue rather than in the vessel.

Fig. 28-3: Macular lesion seen on upper lip due to blunt trauma.

Diagnosis

- **Clinical diagnosis**—macular lesion with history of blunt trauma.

Management

- It is not required, if the diagnosis is confirmed.

Cervicofacial Emphysema

It is a swelling occurs due to introduction of gas or air in the interstices of the connective tissue. In orofacial region, forced air may spread to mediastinal and retropharyngeal area.

Etiology

- **Dental procedure**—it follows variety of oral and dental procedures like tooth extraction, blowing of compressed air into the root canal during endodontic treatment or into a periodontal pocket, blowing of air from high speed air rotor machine.
- **Fracture**—it can also follow mid facial fractures.
- **Surgical procedure**—it can occur spontaneously as a result of patient's breathing actions following some type of surgical procedure with the break in tissue permitting air to enter the connective tissue space. In some cases, while surgical operation, compressed air may be forced in small intraoral laceration.

Clinical Features

- **Symptoms**—patient complains of pain and 'bubbling' sensation while palpating the tissue and often difficulty in breathing.
- **Appearance**—it is manifested as unilateral swelling of the tissues of face and/or neck which occurs very rapidly.
- **Crepitus**—it can be felt while auscultating the swelling.
- **Mediastinal involvement**—spread to mediastinum will result in dysphonia, dysphagia or dyspnea.
- **Hamman's crunch**—cardiac auscultation reveals crepitus synchronous with the heart beat in case of mediastinum involvement.
- **Pneumoparotid**—it occurs when air enters parotid duct. It appears as unilateral enlargement of the parotid. Milking of parotid duct produce frothy air filled saliva.

Diagnosis

- **Clinical diagnosis**—history and presence of crepitus on palpation are two important diagnostic indicators for cervicofacial emphysema.

Management

- **Antibiotics therapy**—usually broad spectrum antibiotics are prescribed for dental related cervicofacial emphysema. It usually resolves in 2 to 5 days of time.
- **Management of pneumoparotid**—these are treated with antibiotics, massage, hydration, sialogogues and warm compress.

Factitious Injury

Factitious disorders are characterized by physical or psychological symptoms produced intentionally to assume the sick role. A symptom can be considered intentionally produced if there is direct evidence or if other causes for the symptom have been excluded. A patient presenting with a factitious illness typically has a personality disorder with prominent borderline traits. These patients, when confronted with the possibility that their illness was self-inflicted, typically deny the accusations, become angry. Treatment of this disorder is difficult. Perhaps the best treatment may be recognized that it exists so that unnecessary procedures can be avoided. A factitious patient will rarely seek psychiatric treatment. When our patient was confronted with the possibility that her problem was self-inflicted, she vehemently denied the accusations.

Self-inflicted injury is the most common in subcutaneous emphysema. Therefore, when a patient presents with unexplained recurrent subcutaneous emphysema, one should suspect self-infliction and examine for puncture marks.

There may be circular purpura around the mouth. In some cases patient give injury to area to get relief from the pain (Fig. 28-4). This is more common in rural population.

Fig. 28-4: Factitious injury seen on the neck of patient to get relief from the pain.

Traumatic Injury to Teeth

There are various causes of traumatic injuries to teeth like falls, collisions, sporting activities, domestic violence, automobile accident and assault.

Factors Affecting Trauma to Teeth

- *Energy of impact*—this factor includes both mass and velocity. Low velocity blows cause the greatest damage to the supporting structure whereas the high velocity blows are usually not associated with damage to the supporting structure.
- *Resiliency of impacting object*—if the tooth is struck with cushioned object or if the lip absorb and distribute the impact, the chances of crown fracture are reduced while the risk of luxation and alveolar fracture is increased.
- *Shape of impacting object*—a sharp impact favors clean crown fracture with minimum displacement of the tooth because the energy is spread rapidly over a limited area. On the other hand, a blunt impact increases the area of resistance and force in the crown is transmitted to the apical region causing luxation or root fracture.
- *Direction of the impacting force*—impact can meet the tooth at different angles, most often hitting the tooth facially, i.e. perpendicular to the long axis of the root. Depending upon on the direction of the impacting force the type of fracture properties of enamel and dentin; it was seen that enamel is weakest in region parallel to the enamel rods and that dentin is easily fractured when force is perpendicular to the dentinal tubules.

Classification

Ellis and Davey's classification

- *Class I*—simple fracture of the crown involving enamel.
- *Class II*—extensive fracture of the crown, with considerable amount of dentin involved but no pulp exposure.
- *Class III*—extensive fracture of the crown with considerable amount of dentin involved with pulp exposure.
- *Class IV*—traumatized tooth becomes nonvital (with or without loss of crown structure).
- *Class V*—tooth lost due to trauma.
- *Class VI*—fracture of root with or without loss of crown structure.
- *Class VII*—displacement of the tooth without crown or root fracture.
- *Class VIII*—fracture of crown and mass.
- *Class IX*—fracture of deciduous teeth.

Classification by Andreessen

This classification is based on a system adopted by WHO in its application of the international classification of disease to dentistry and stomatology.

- *Injuries to the hard dental tissues and pulp*
 - *Crown infraction*—an incomplete fracture of the enamel without loss of the tooth substance.
 - *Uncomplicated crown fracture*—it is restricted to enamel or involves enamel and dentin, but does not expose the pulp.
 - *Complicated crown fracture*—a fracture involving enamel and dentin and exposing the pulp.
 - *Complicated crown root fracture*—a fracture involving enamel, dentin and cementum and exposing pulp.
 - *Root fracture*—a fracture involving dentin, cementum and the pulp.
- *Injuries to the periodontal tissue*
 - *Concussion*—an injury to the tooth supporting structures without abnormal loosening or displacement of the tooth, but with marked reaction to percussion.
 - *Subluxation*—an injury to the tooth supporting structure with abnormal loosening but without displacement of tooth.
 - *Intrusive luxation* (central dislocation)—displacement of the tooth into alveolar bone. This injury is accompanied by comminution or fracture of the alveolar socket.
 - *Extrusive luxation* (peripheral dislocation)—partial displacement of the tooth out of its socket.
 - *Lateral luxation*—displacement of the tooth in a direction other than axially. This is accompanied by comminution or fracture of the alveolar crest.
 - *Extra-articulation* (complete avulsion)—complete displacement of the tooth out of its socket.

- *Injuries of the supporting bone*
 - *Comminution of alveolar socket*—crushing and compression of the alveolar socket. This condition was found with intrusive and lateral luxation.
 - *Fracture of the alveolar socket wall*—a fracture contained to the facial or lingual socket walls.
 - *Fracture of the alveolar process*—a fracture of the alveolar process which may or may not involve the alveolar socket.
 - *Fracture of mandible and maxilla*—a fracture involving the base of the mandible or maxilla and often the alveolar process. The fracture may or may not involve the alveolar socket.
- *Injuries to gingiva and oral mucosa*
 - *Laceration of gingiva or oral mucosa*—a shallow or deep wound in the mucosa resulting from a tear and usually produced by a sharp object.
 - *Contusion of gingiva or oral mucosa*—a bruise usually produced by impact from a blunt object and not accompanied by a break of the submucosal hemorrhage.
 - *Abrasion of gingiva or oral mucosa*—superficial wound is produced by rubbing or scrapping of the mucosa leaving a raw bleeding surface.

Classification by Garcia Godoy

- 0—Enamel crack.
- 1—Enamel fracture.
- 2—Enamel, dentin, fracture without pulp exposure.
- 3—Enamel, dentin fracture with pulp exposure.
- 4—Enamel dentin cementum fracture without pulp exposure.
- 5—Enamel dentin cementum fracture with pulp exposure.
- 6—Root fracture.
- 7—Concussion.
- 8—Luxation.
- 9—Lateral displacement.
- 10—Intrusion.
- 11—Extrusion.
- 12—Avulsion.

Concussion

In this case, there is some injury to the supporting structures without abnormal loosening or displacement of teeth and occurs due to crushing injury to the vascular structure at apex and to the periodontal ligament with resulting inflammatory edema.

Clinical Features

- *Symptoms*—traumatized tooth is sore.
- *Signs*—it is sensitive to horizontal and vertical percussion and biting force.

Radiographic Features

- *PDL space widening*—widening of periodontal ligament space in the apical portion.
- *Reduce pulp canal size*—reduction in the size of the pulp canal after a year following the trauma.

Management

- *Conservative*—adjustment of opposing teeth should be done to avoid pain.

Luxation

It is the dislocation or disarticulation of teeth which are abnormally mobile and are displaced. There may be complete or partial necrosis of the pulp.

Types

- *Subluxation*—it denotes abnormal loosening of teeth without frank dislocation.
- *Intrusive luxation*—displacement of teeth into the alveolar bone.
- *Extrusive luxation*—partial displacement of teeth out of the socket.
- *Lateral luxation*—movement other than axial displacement.

Clinical Features

- *Site*—teeth commonly involved are maxillary incisors in both dentitions.
- *Symptoms*—teeth are abnormally mobile. Pain is also present.
- *Signs*—bleeding from the gingival crevice indicating periodontal damage. Tooth is extremely sensitive to percussion and masticatory force. Clinical crown may appear shortened in case of intrusive luxation.
- *Sequelae of luxation*—there may be external root resorption, ankylosis of tooth, obliteration of root canals, pulp necrosis and marginal bone loss.

Radiographic Features

- *Tooth elevation*—elevation of traumatized tooth.
- *PDL space widening*—widening of apical portion of periodontal ligament space.
- *Pulp chamber obliteration*—in intrusion, partial or complete obliteration of pulp chamber may occur.

Management

- *Subluxation*—if several teeth are traumatized or subluxated, a splint may be placed to stabilize the involved teeth during the healing phase. Follow-up care

is mandatory for these injuries because of the greater potential for pulpal necrosis. A splint can be removed within 7-10 days.

- *Extrusive luxation*—the clinician first repositions the luxated tooth into its alveolar socket. If a clot has formed apical to the displaced tooth, the tooth may be more difficult to reposition and more manipulation and pressure may require. It requires splint to be used to stabilize the tooth during the healing process for 2 to 3 weeks. The tooth should be examined clinically and radiographically at monthly interval. If the periapical lesion appears or a fistula is present, endodontic therapy becomes a major consideration.
- *Lateral luxation*—the repositioning of laterally luxated tooth requires a more forceful degree of reduction because of the type or displacement that has occurred. Manipulation with the thumb and index finger can often reduce the injured tooth. The laterally luxated tooth should be repositioned, first by forcing the displaced apex out of its locked position within the labial bone, allowing the clinician to place axial pressure in an apical direction and to manipulate the tooth into its natural position. Splinting is required routinely after reduction of lateral luxation injuries. Maintain the splint for minimum of 14 days and remove it when no abnormal mobility is associated with the tooth.
- *Intrusive luxation*—the best policy is to wait and watch for the tooth to re-erupt on its own accord. Surgical and orthodontic extrusion should be done. Root canal therapy must be anticipated in almost all intrusive luxation injuries.

Avulsion

It is complete displacement of tooth from its alveolus.

Clinical Features

- *Age*—encountered in a relatively younger age
- *Site*—maxillary central incisors are commonly affected. Teeth may be missing from the arch (**Fig. 28-5A**).
- *Associated signs*—fracture of the alveolar wall and lip injuries are frequently seen.

Radiographic Features

- *Socket without tooth*—presence of dental socket without correspondent tooth. Tooth may be located in the adjacent soft tissue.
- *Noticeable lamina dura*—if recent wound is seen, lamina dura will be noticeable.
- *Socket sclerosis*—socket sclerosis occurs.

Figs 28-5A and B: Missing tooth from the arch in Figure A and sample tooth is kept in saline solution in Figure B (Courtesy Dr Shetty).

Management

- *Management at site of injury*—replant immediately, if possible. If contaminated, rinse with water before implanting. When immediate implantation is not possible, place the tooth in the transport Medias like milk, saline (**Fig. 28-5B**), saliva and if none of the above is present, use water.
- *Replantation of tooth*—it refers to the insertion of a vital or non-vital tooth into the same alveolar socket from which it was removed or otherwise lost. If extra-oral dry time is less than 2 hours, replant immediately and of extraoral dry time is greater than 2 hours then soak in a topical fluoride solution for 5-20 minutes, rinse with saline and replant. If tooth has been in physiological storage media, then replant immediately.
- *Management of the root surface*—keep the tooth moist at all times and do not handle the root surface. If the root surface is contaminated, rinse with saline and if persistent debris remains on the root surface then use

cotton pellet to remove the remaining debris and/or gently brush off the debris with a wet sponge.

- *Management of socket*—gently aspirate without entering the socket. If a clot is present, use light irrigation with saline. Do not make surgical flap unless bony fragment prevents replantation.
- *Root canal treatment*—mature tooth with complete root formation must have root canals filled before implantation or else pulp necrosis will result. If root canals are not filled, there is gradual obliteration of the pulp chamber and canals by calcification.
- *Splinting*—splinting can be done by using a variety of appliance including stainless steel wires, acrylic splints, orthodontic banding and arch wires with wire ligatures and even surgical cements with gauze. In some cases root resorption begins within a week or to a few months or as long as 10 years.
- *Transplantation of teeth*—it is the replacement of teeth which is damaged beyond repair by caries or by means of other teeth. Usually, mandibular first molar is replaced by developing third molar. Transplanted teeth have to be esthetically acceptable with no periapical or lateral lesions, sharing adequately in the maintenance or physiologic maxillomandibular and muscular relations. Homologous transplants of preserved frozen teeth have also been proposed to simplify the process.

Bruxism

The word *bruxism* is taken from the Greek word *brychein*: gnashing of teeth. Although the term *bruxism* is not generally known to lay people, it is shorter and more convenient than *teeth clenching or grinding*. *Bruxism* can perhaps be best defined as the involuntary, unconscious and excessive grinding, tapping, or clenching of teeth. When it occurs during sleep, it may be best called as *sleep or nocturnal bruxism*. A few people, on the other hand, brux while they are awake, in which case the condition may be called *wakeful or diurnal bruxism*.

All forms of bruxism entail forceful contact between the biting surfaces of the upper and lower teeth. It is also called as '*night grinding*' or '*bruxomania*'. It is a habitual grinding of the teeth, either during sleep or as an unconscious habit during waking hours. It is the term used both for clenching habit during which pressure is exerted on the teeth and periodontium by the actual grinding or clamping of the teeth and, also to repeated tapping of the teeth.

Etiology

- *Local*—mild occlusal disturbances, unconscious attempt by the patient to establish a greater number of teeth in contact or to counteract a local irritating situation.
- *Systemic factors*—gastrointestinal disturbances, sub-clinical nutritional deficiency and allergy or endocrine disturbances have been reported to be the causative factors.
- *Psychological factors*—emotional tension in which patient is unable to express his emotion due to fear, rage, rejection and it becomes hidden in subconscious and later expressed by variety of way like by grinding the teeth.
- *Occupational*—like in cases of watchmaker, persons who chew gum, tobacco or objects such as toothpicks or pencils.

Clinical Features

- *Symptoms*—in grinding and tapping, this is contact which involves movements of the lower jaw and unpleasant sounds which can often awaken housemates. Clenching (or clamping) on the other hand, involves inaudible, sustained, forceful teeth contact unaccompanied by mandibular movements. Long-term bruxers sometimes experience jaw tenderness, jaw pain, fatigue of facial muscles, headaches, neckaches, earaches and hearing loss.
- *Teeth*—chronic bruxism may lead to sensitive, worn-out, decayed, fractured, loose or missing teeth. Grinding or clenching breaks down the enamel; sometimes in long-term bruxers, the teeth height is reduced to stumps (Fig. 28-6). Instead of a white enamel cover, one often sees the more yellowish and softer dentin. The posterior teeth of some chronic bruxers often lose their cusps and natural contours, appearing instead flat, as if they had been worked over with a file or sandpaper. When anterior teeth are affected, their biting surfaces are damaged.

Fig. 28-6: Attrition seen lower anterior region in chronic bruxers.

- *Dental caries formation*—the absence of enamel makes it easier for the bacteria to penetrate the softer part of the teeth and produce cavities. With time, the condition may lead to bridges, crowns, root canals, implants, partial dentures and even complete dentures. As long as bruxism continues, the situation keeps getting worse. Thus, by 40 or 50 years of age, most patients have worn their teeth to the degree that extensive tooth restorations have to be performed.
- *Appearance*—as the teeth wear out, they become shorter. As a result, when the mouth is closed, the upper and lower jaws are nearer than they used to be and hence the nose and chin. The skin now may bag below the eyes and curl around the lips, causing the lips to seemingly disappear. The chin recedes and the person looks comparatively old.
- *Facial muscles*—bruxism involves excessive muscle use leading to a build-up or enlargement (hypertrophy) of facial muscles, especially those of the jaws where the masseter muscle (the muscle that raises the lower jaw and enables closing the jaws) is located. In long-term bruxers, this build-up may lead to a characteristic square-jaw appearance. Some patients resort to removing part of the masseter muscle by surgery or injections of toxic materials to reduce muscle size and thus partially regain their former, more aesthetically pleasing look.
- *Salivary glands*—another example of this spiral involves the occasional inflammation and blockage of some salivary glands. In this case, the masseter muscle becomes disproportionately overdeveloped and blocks the opening of the nearby parotid glands. They, thus interfere with the flow of saliva into the mouth, causing the saliva to accumulate in the glands. This in turn may lead to periodical swelling, pain, inflammation and abnormal dryness of mouth.
- *TMJ*—bruxism may also damage the temporomandibular joints. First few signs of temporomandibular joint disorders are TMJ discomfort or pain, soreness of jaws and muscles, clicking or popping sounds when opening the jaws or while chewing and difficulties in opening the mouth fully.
- *Malocclusion*—malocclusion or bad bite is more common among bruxers than in the general population. Bruxism may often involve more pressure on one side of the mouth than on the other, thereby causing malocclusion. As the teeth wear out (**Fig. 28-7**), the distance between the upper and lower jaw decreases and overclosure may develop.
- *Effect on periodontium*—There may be loss of integrity of the periodontal structures resulting in loosening or drifting of the teeth and even gingival recession occurs.

Fig. 28-7: Severe destruction tooth seen in bruxism patient.

Management

- *Psychotherapy*—the belief that bruxism is traceable to stress and other emotional and psychological factors give rise to a variety of psychotherapeutic approaches. For instance, listening to progressive relaxation or autosuggestion tapes just before going to sleep may foster calmness and self-confidence.
- *Wakeful EMG Feedback*—another psychological approach to stress reduction resorts to instrumentation. During bruxing, the relevant muscles are active and this increased activity or tension can in turn be measured with an electromyograph (EMG: electro—electric; myo—muscle; graph—record). During treatment sessions at home or the laboratory, the patient sits or reclines comfortably. One or more pairs of recording electrodes are then attached to the surface of the skin in close contact to appropriate muscles (e.g. masseter muscles). These electrodes transmit information about the level of muscle activity to a computer monitor. The patient is instructed to consciously lower that level below a threshold line (also visible on the screen). Gradually, by becoming alert to the presence of muscle tension, patients may develop techniques for reducing that tension and hence, bruxism.
- *Exercise*—Quinn suggested isokinetic and stretching exercises of the mandible. Such exercises may or may not help alleviate bruxism, but perhaps may be used to complement other approaches. However, but it seems unlikely that they could ever be used as the sole therapeutic approach. Evidences that this approach is effective and non-existent.
- *Drugs*—both, the stress and brain malfunction etiological theories give at times, rise to the use of anti-anxiety agents, muscle relaxant and other drugs. Most authorities, however, feels that at best, drugs in use now are of limited value in the treatment of great majority of

chronic bruxers and that they often involve moreover untoward side effects. Evidence that this approach is effective and are non-existent.

- *Equilibration therapy*—some people believe that bruxism is traceable to malocclusion (bad bite). They therefore suggest eliminating this cause through orthodontic adjustment.
- *Splints*—by far, the most common treatment regimen for bruxism relies on the time-honored procedure of splints like nightguards, biteguards, occlusal splints, biteplates, removable appliances or interocclusal orthopedic appliances and use of manufactured customized appliances. Removable splints are worn at night to guide the movement so that periodontal damage is minimal.

Fracture of Teeth (Fig. 28-8)

Dental Crown Fracture

Anterior teeth are commonly involved. It may be caused by fall, accident and blows from foreign bodies.

Fig. 28-8: Injuries to hard dental tissues and pulp.

Types

- *Enamel infraction or crack*—fracture that involves only enamel without loss of enamel substance.
- *Uncomplicated fracture*—fracture involving enamel or enamel and dentin with loss of tooth substance without pulpal involvement.
- *Complicated fracture*—fracture that extends through enamel, dentin and pulp with loss of tooth substance.

Clinical Features

- *Cracks*—it can be seen in indirect light (directing the beam along the long axis of tooth).

Figs 28-9A and B: Uncomplicated fracture of crown of teeth (Courtesy Dr Shetty).

- *Uncomplicated fracture*—it does not involve pulp and is usually found on mesial or distal corner of maxillary central incisors (Figs 28-9A and B). Dentin involvement is identified by contrast of color between it and peripheral layer of enamel. Exposed dentin is very sensitive to chemical, thermal and mechanical stimulation.
- *Complicated fractures*—there is bleeding from exposed pulp or at least drop of blood oozes from the pinpoint exposure. Exposed pulp will be sensitive to most forms of stimulation (Figs 28-10A and B).

Radiographic Features

- *Appearance*—it will show size and position of pulp chamber, location and extent of exposure and stage of root development.

Management

- *Crown infraction*—no treatment (Fig. 28-11).
- *Uncomplicated fracture*—small defect is corrected by grinding. Oblique fracture has worse prognosis than

Figs 28-10A and B: Complicated crown fracture of upper central incisor (Courtesy Dr Shetty).

Fig. 28-11: Crown fracture involving the enamel and dentin.

horizontal fracture. Provide a temporary glass-ionomer cement bandage or permanent restoration using a bonding agent and composite resin. If very close to pulp, consider $\text{Ca}(\text{OH})_2$ base. If an intact fragment exists, a bonding procedure may be carried out.

- **Complicated fracture**—pulp capping, pulpotomy and pulpectomy can be done. In immature tooth: Perform pulp capping or partial pulpotomy with calcium hydroxide and bacteria tight coronal seal. In mature tooth: Same as with immature tooth or pulpectomy.

Dental Root Fracture

Clinical Features

- **Sites**—it is common with maxillary central incisors.
- **Coronal fragment**—coronal fragment is displaced lingually and is slightly extruded. If fracture line is close to the apex then tooth will be more stable (**Fig. 28-12A**).
- **Signs**—if only movement of crown is detected, root fracture is likely to be considered.
- **Symptoms**—temporary loss of sensitivity. It returns to normal within 6 months.

Fig. 28-12A: Root showing fracture at the apex of root (Courtesy Dr Soni).

Radiographic Features

- **Appearance**—if the X ray beam is projected parallel with the plane of the root, sharp radiolucent line between the fragments can be seen (**Fig. 28-12B**). If the X-ray beam is not parallel, it will look as poorly defined gray shadow.
- **Fracture line**—fracture line may be transverse or oblique.
- **Obliteration of pulp chamber**—calcification and obliteration of pulp chamber can be seen in due course of time.

Differential Diagnosis

- **Soft tissue image**—it extends beyond tooth margin.

Management

- **Fracture in middle or apical third of root**—teeth mainly restored to their proper position and securely immobilized.
- **Fracture at coronal/cervical area**—extraction is indicated.

Fig. 28-12B: Fracture root in apical region.

Crown/Root Fracture

Such fracture is likely to be intra- and extra-alveolar. They are result of direct trauma.

Clinical Features

- *Site*—they have labial margin in the gingival third and course obliquely to exist below the gingival attachment on the lingual surface. It frequently involves pulp (Fig. 28-13).
- *Symptoms*—there is pain during mastication.
- *Signs*—tooth is sensitive to occlusal force.

Fig. 28-13: Crown/root fracture of upper central incisor due to severe attrition of tooth.

Radiographic Features

- *Appearance*—most crown/root fractures are perpendicular to the direction of the beam.

Management

- *Removal of coronal fragment*—this can be done and after this, dowel crown should be prepared.
- *Extraction*—if 3 to 4 mm of root is remaining, extraction is indicated.
- *Uncomplication fracture*—uncomplicated fracture is to be restored.

Vertical Root fracture

It is also called as 'Cracked tooth syndrome'. It runs length-wise from crown towards apex of tooth.

Causes

- *Iatrogenic*—they are iatrogenic in origin, i.e. after insertion of pin or retention screws into vital and non-vital teeth.
- *Endodontically treated tooth*—it also occurs in endodontically treated tooth as there is weakening of tooth in such cases.
- *Traumatic occlusion*—it may be caused by traumatic occlusion.

Clinical Features

- *Site*—it is usually seen in posterior teeth in adults, especially in mandibular molars.
- *Symptoms*—dull pain of long duration which may vary from non-existent to mild.
- *Signs*—it may have periodontal lesions resembling chronic lesion.
- *History*—history of repeated failure of endodontic treatment.

Radiographic Features

- *Appearance*—if central X-ray lies in the plane of the fracture, it may be visible as a radiolucent line.
- *PDL thickening*—after bacterial invasion, radiograph will show thickening of periodontal ligament space or a diffuse radiolucent lesion.

Management

- *Extraction*—extraction of single rooted teeth.
- *Hemisection*—hemisection for multi-rooted tooth followed by extraction of involved half and the remaining half is restored with endodontic therapy.

Perforation of the Root

The root canal is sometimes penetrated during operative procedures and injury may extend to cause a perforation of the root. The usual site of it is at the apex and the side of the root, but the floor of the pulp chamber and even the side of

the crown; near the neck of the tooth may be perforated (Fig. 28-14).

Radiographically, it is visible if some smooth metal broach or piece of wire or some opaque substance is inserted in the abnormal passage to make it visible. In some cases, the shadow of root canal can be seen approaching the side of the root and this can be the evidence of a perforation. Rarefying osteitis at the side of a tooth is always suggestive of perforation, particularly if there has been root canal therapy.

Fig. 28-14: Root perforation seen in the central incisor (Courtesy Dr Soni).

Tooth Ankylosis

Ankylosis between tooth and bone is an uncommon phenomenon in the deciduous dentition and even more rare in permanent teeth.

Causes

- *Partial root resorption*—it occurs when partial root resorption is followed by repair; with either cementum or bone that unite the tooth root with alveolar bone.
- *Occlusal trauma*—ankylosis can occur after traumatic injury particularly due to occlusal trauma.
- *Following root canal therapy*—it may follow root canal therapy, if the apical periodontal ligament is irritated or seriously damaged.

Clinical Features

- *Symptoms*—it seldom manifests any clinical symptoms unless there is concomitant pulp infection.
- *Dull muffled sound*—if the extensive area of the root surface is involved, the tooth gives a dull muffled sound on percussion rather than the normal sharp sound.
- *Difficulty in extraction*—there is considerable difficulty while doing extraction of the teeth, sometimes necessitating surgical removal.

Radiological Features

- *Loss of PDL space*—it may be visible on the radiograph as loss of the normal thin radiolucent line representing the periodontal ligament.
- *Sclerosis*—there may be mild sclerosis and apparent blending of the bone with the tooth root.

Management

- It has good prognosis and as such no treatment is required.

Traumatic Injury to Facial Bone

When patient is subjected to injury, there is chance that jaws may be fractured. Even in some cases, minor trauma may result in bone damage.

Radiographic Features of Fracture

There are mainly following features seen in fracture of jaws:

- *Fracture line*—dark line which results from the passage of rays through the line of cleavage has been termed as the fracture line. Fracture line is very dark, when the rays pass freely between the fragments and less dark when the rays pass through small part of the fracture line.
- *Displacement of the fragment*—in it, instead of normal continuity of the surface of bone, there is dis-alignment of the two fragments. In mandible, action of temporalis muscle pulls the posterior portion of the mandible upward is the common cause of displacement.
- *Deformity*—it is alteration in shape of bone as a result of injury in the cortex. The abrupt angulations of bone are indication of deformity.
- *Radiopaque line*—a fracture that has become impacted does not have any space between the fragments and the line of cleavage is obscured by superimposition of bony trabeculae at the site of impaction. In this case, there is slight increase in density at the fracture line due to double number of trabeculae.
- *Double fracture line*—many fractures pass slight obliquely across the bone. When the line of cleavage of inner and outer cortices does not superimpose, it gives an impression that there are two fractures.
- *Relationship of teeth to fracture line*—a fracture may enter the apical end of the tooth socket and disappear. If the line of fracture extends along a lateral aspect of the tooth, the tooth may obscure it. Fracture through the angle of the jaw frequently appears to extend from the apices of the 3rd molar but it has actually started at the alveolar margins of bone. An unerupted tooth may sometimes be present in the fracture line, which might play as predisposing factor in fracture and its presence may

affect the treatment. With fracture, a tooth may be forced from its follicle into the adjacent bone, soft tissue or between the fragments; causing its separation.

Indication for Removal of a Tooth from the Fracture Line

- Longitudinal fracture involving the root.
- Dislocation or subluxation of the tooth from the socket.
- Presence of periapical infection and infected fracture line.
- Acute Pericoronitis, advanced periodontitis.

Dentoalveolar Fractures

These are defined as those in which avulsion, subluxation or fracture of teeth occur in relation with fracture of the alveolus. Anterior alveolar fractures are most common. Labial plate is more prone to fracture than palatal plate. Fracture line is most often horizontal.

Clinical Features

- *Site*—alveolar process of maxilla is more commonly fractured than that of mandible. The most common sites are the upper incisor and cuspid regions and region of tuberosity.
- *Lip*—there is full thickness wound of the lower lip or ragged laceration on its inner aspect caused by impaction against the lower anterior teeth. There may be local bruising and portions of teeth or foreign bodies may get lodged in soft tissue of lip.
- *Gingiva*—there may be laceration of gingiva and deformity of alveolus.
- *Teeth*—there may be fracture of crown and root portion of teeth. Teeth in fractured fragment will have recognizable dual sound when percussed.
- *Occlusion*—marked malocclusion along with displacement and mobility.
- *Alveolar fracture*—a complete alveolar fragment may be displaced into the soft tissue of the floor of mouth and can be covered by mucosa. There may be gross comminution of alveolus occurs.
- *Maxillary tuberosity fracture*—the detached bone may include the floor of maxillary sinus (**Fig. 28-15**); which is indicated by discharge from the nose on the involved side. Ecchymosis of buccal vestibule can also occur.
- *Cracked pot noise*—impacted alveolar fracture may be virtually immobile. Sometimes crepitations can be detected on palpation and a 'cracked pot' noise is detected when the teeth within the alveolar fracture are percussed.

Radiological Features

- Radiologically, fracture line is seen above the apices of root of teeth.

Fig. 28-15: Fracture of maxillary tuberosity showing detachment.

Fig. 28-16: Dentoalveolar fracture showing line distal to central incisor.

- Damage to roots of the adjacent teeth is common with fracture of alveolus (**Fig. 28-16**). Fracture of alveolar process is well delineated. Posterior palatal fracture is best demonstrated on occlusal radiograph.

Management

- *Fracture of maxillary tuberosity*—if the tuberosity is completely detached from the periosteum, it should be carefully dissected out and the resulting soft tissue defect are sutured to prevent any residual opening into the maxillary sinus.
- *Extensive fracture of alveolus with teeth attached*—splinting of teeth and anchoring to teeth elsewhere in the upper jaw.

Mandibular Fractures

Fracture of mandible occurs more frequently than any other fracture of the facial skeleton. It is more common than middle third fracture. The most common facial fractures are mandible (61%), followed by maxilla (46%), the zygoma

(27%) and the nasal bones (19%). Most common cause of mandibular fracture is road traffic accidents. Other causes are assault, falls, industrial trauma and sport injury.

Classification

- *According to type of fracture:*
 - *Simple*—it includes closed linear fracture of the condyle, coronoid, ramus and edentulous body of the mandible. Greenstick fracture occurring in children is also included in it.
 - *Compound*—fracture of tooth bearing portions of the mandible are nearly always compound into the mouth via the periodontal membrane and some severe injuries are compound through the overlying skin.
 - *Comminuted*—direct violence to mandible from penetrating sharp objects and missiles are usually compound and may be further complicated by bone and soft tissue loss.
 - *Pathological*—when fractures result from minimum trauma to mandible which is already weakened by pathological conditions like osteomyelitis, neoplasm and generalized skeletal diseases.
- *According to site of fracture:*
 - Dentoalveolar
 - Condyle
 - Coronoid
 - Ramus
 - Angle
 - Body (molar and premolar)
 - Parasymphysis
 - Symphysis
- *According to cause of fracture:*
 - *Direct violence*—fracture occurs at the site of trauma.
 - *Indirect violence*—fracture occurs away from the site of trauma.
 - *Excessive muscular contraction*—occasionally, fractures of coronoid process occur because of sudden reflex contracture of temporalis muscle.
- *According to treatment plan*
 - *Unilateral*—it is more frequently caused by direct violence.
 - *Bilateral*—it occurs due to combination of direct and indirect violence.
 - *Multiple*—it is also associated with direct and indirect violence. Most common fracture of this type is Guardsman fracture when soldier faints on parade at midpoint of chin causing fracture of symphysis and both the condyle.
 - *Comminuted*—it is usually seen in war missile injury (Fig. 28-17).
- Fry and colleagues classified, in descriptive manner, the different directions of the fracture:

Fig. 28-17: Comminuted fracture of body of mandible.

- *Horizontal favorable*: if the direction of the fracture is such that it resists the action of the elevator muscles in pulling the ramus segment upwards when viewed from side, or horizontal plane called as horizontally favorable fracture.
- *Horizontally unfavorable*: when the direction of fracture line is reversed and posterior fragment is elevated by the muscle pull, the fracture called as horizontally unfavorable (Fig. 28-18).
- *Vertically favorable*: when viewed from above or in the vertical plane, the buccolingual direction of the fracture line is such that it prevents the displacement of the segment lingually by resisting the pull of the medial pterygoid muscle called as vertically favorable.
- *Vertically unfavorable*: when the opposite is the case, in which the segment can be pulled lingually because of the unopposed action of the medial pterygoid, the fracture is termed as vertically unfavorable.

Fig. 28-18: Horizontally unfavorable fracture of the angle of mandible and parasymphyseal fracture involving the teeth in fracture line.

Clinical Features of Mandibular Fracture

- *Changes in the occlusion*—any change in the occlusion is highly suggestive of the mandibular fracture. A change in the occlusion can result from fractured teeth, a fractured alveolar process, a fractured mandible at any location, and trauma to the temporomandibular joint and muscles of mastication. Posttraumatic premature posterior dental contact or anterior open bite may result from bilateral fractures of the mandibular condyle or angle as well as from maxillary fractures with inferior displacement of the posterior maxilla. Posterior open bites may occur with the fractures of the anterior alveolar process or parasymphiseal fractures. Unilateral open bite may occur owing to ipsilateral angle and parasymphiseal fracture (**Fig. 28-19**). Posterior cross bite can result from midline symphyseal and condylar fractures with splaying of the posterior mandibular segments.

Fig. 28-19: Step deformity seen in the fracture of mandible in the symphysis region.

- *Anesthesia, paresthesia, or dysesthesia of the lower lip*—Numbness in the distribution of the inferior alveolar nerve after trauma is almost pathognomonic of a fracture distal to the mandibular foramen.
- *Abnormal mandibular movement*—most patients presenting with a fractured mandible have limited opening and trismus owing to guarding of muscles of mastication. Certain mandibular fractures result in predictable abnormal mandibular movements like deviation on opening towards the side of a mandibular condylar fracture (**Fig. 28-20**). Because lateral pterygoid muscle function on the unaffected side is not counteracted on the opposite side by the nonfunctioning of lateral pterygoid muscle, deviation results. Inability to close the jaws can be the result of fractures of the alveolar process, angle, ramus, and symphysis, causing

Fig. 28-20: Fracture mandible showing deviation on opening.

premature dental contact. Lateral mandibular movements may be inhibited by bilateral condylar fractures and fracture of ramus with bone displacement.

- *Change in facial contour and mandibular arch form*—facial asymmetry should alert clinician to the possibility of mandibular fracture. A retruded chin can be caused by bilateral parasymphiseal fracture. The appearance of an elongated face may be the result of bilateral subcondylar, angle, or body fracture, allowing the anterior mandible to be displaced downward. If there is a deviation from the normal U-shaped curve of the mandible, fracture should be suspected.
- *Lacerations, hematoma and ecchymosis*—trauma significant enough to cause loss of skin or mucosal continuity or subcutaneous-submucosal bleeding certainly can result from trauma to the underlying mandible. Lacerations should be carefully inspected before closure. The direction and type of fracture may be visualized directly through the laceration. In rare cases of animal bites there may be the loss of soft as well as hard tissue. The diagnostic sign of ecchymosis or hematoma in the floor of the mouth indicates mandibular body or symphyseal fracture.

Radiographic Features

- *Technique required*—following types of radiographs are helpful in the diagnosis of mandibular fractures, i.e. panoramic (**Figs 28-21 and 28-23**) radiograph, lateral oblique radiograph, posteroanterior radiograph, occlusal view, periapical view, reverse Towne's view, CT scan.
- *Margin of fracture*—the margins of the fractures usually appear as sharply defined radiolucent lines of separation that are confined to the structure of the mandible. Occasionally the margins of the fracture overlap each other, resulting in the area of increased radiopacity at the fractured site.

Fig. 28-21: Fracture at angle of mandible on left side.

Fig. 28-23: Fracture at symphysis and angle of mandible.

Fig. 28-22: Fracture at body of the mandible.

Fig. 28-24: PA view showing multiple fractures of the mandible.

- *Step*—displacement of the fracture results in the cortical discontinuity or “step.”
- *Double fracture line*—an oblique fracture that involves both cortical plates may show two fracture lines if the fracture lines in both buccal and lingual plates are not superimposed. In this case, a right angle view such as occlusal view and the fact that the two fracture lines are meeting at same point on the inferior border of the mandible helps in correction of diagnosis.
- *Lateral oblique view*—the lateral oblique view of the mandible can be helpful in the diagnosis of ramus, angle and posterior body fractures (Fig. 28-22).
- *PA view*—the posteroanterior view demonstrates any medial or lateral displacement of the fractures of ramus, angle, body or symphysis (Fig. 28-24).
- *Occlusal view*—the mandibular occlusal view demonstrates displacement in the lateral or medial direction of the body fractures and also shows the anterior or posterior displacement of the symphyseal fracture.
- *Reverse Towne’s view*—the reverse Towne’s view is ideal for showing medial displacement of the condyle and

condylar neck fracture. Periapical dental film shows the most detail and can be used for the nondisplaced linear fractures of the body as well as alveolar process and dental trauma.

- *CT scan*—the CT scan is ideal for the condylar fractures that are difficult to visualize. The greater expenses and radiation exposure limit its use in cases that cannot be diagnosed with conventional radiograph (Figs 28-25A to 28-26).

Differential Diagnosis

- *Soft tissue shadow of space between tongue and soft palate*—in lateral radiograph of normal mandible, it is possible to see the gray shadow of tongue which has curved upper and posterior borders. Immediately behind lies the soft palate, which presents a shape somewhat similar to an inverted triangle. In many radiographs, there is a dark line situated between these two shadows which is

Figs 28-25A and B: 3D CT image of mandibular fracture at symphysis region (Courtesy Dr Amit Parate, Lecturer, GDCH, Nagpur, India)

produced by presence of air between the tongue and soft palate. This thin dark line is carried down over the shadow of the mandible in the region of the angle and sometimes gives resemblance to a fracture. Careful study shows that the dark line is continued on the bone.

- *The shadow of hyoid bone*—in lateral radiograph of jaws, the shadow of neck intervenes over the some part of the bone and where it ends anteriorly, there is difference in the radiographic density which is quite marked in some cases. There is greater likelihood of making error when there is thin dark line present which infact represents the subcutaneous fat on anterior aspect of the neck. In either case, there is evidence of shadow continuing on the bone and no fracture can produce such an effect.
- *The intervertebral disc space*—it presents as dark shadow and can be mistaken for fracture. In this case, intraoral occlusal film can be placed in the mouth in occlusal

Fig. 28-26: 3D CT of fracture of mandible (Courtesy Dr Meshram).

plane and X-rays are directed in an appropriate manner, to produce excellent radiographs of this region.

Management

Preliminary management

- *Examination*—the first aid required consists of careful examination of mouth and removal of all fragments of teeth, broken filling and dentures.
- *Airway*—if there is danger of falling tongue back, then dorsum of the tongue should be sutured.
- *Hemorrhage*—obvious bleeding point such as facial vessels should be secured with artery forceps and temporary dressing should be applied.
- *Soft tissue laceration*—soft tissue wound should be sutured within 24 hours of injury.
- *Antibiotics*—benzyl penicillin should be administered IM injection or 1 mega unit every 6 hours for first 2 to 3 days and oral penicillin should be continued for further one week. In recent, oral metronidazole 400-800 mg BD is given to all patients with mandibular fracture.

Planned management

- *Reduction*—reduction of fracture means the restoration of functional alignment of bone fragments.
- *Immobilization of fractured bone*—the fracture site must be immobilized to allow bone healing to occur. Immobilization can be done with intermaxillary fixation and bone plating.

- *Minimally displaced fracture*—close reduction and intermaxillary wiring (**Fig. 28-27**).
- *Severely displaced fracture*—open reduction and intermaxillary fixation.

Fig. 28-27: Fracture with interdental wiring is seen.

Postoperative Care

- *Sitting position*—patient with fracture of mandible finds it more comfortable if they are in sitting position with chin forward, provided that there is no contraindication to this posture such as fracture of vertebra.
- *Drugs*—morphine and its derivative are contraindicated in patients with maxillofacial injuries as these drugs depress the respiratory center and cough reflex. Prophylactic antibiotics should be administered to control the infection. Maintenance of good oral hygiene is essential for prevention of infection.

Coronoid Fracture

It is rare. It usually results from the reflex contracture of the powerful anterior fibers of temporalis muscle. During operation on large cyst of ramus, coronoid may get fracture (**Fig. 28-28**).

Fig. 28-28: Fracture of coronoid is also seen in association with fracture of condyle and mandibular body.

If the tip of the coronoid process is ditched, the fragment is pulled upwards towards the infratemporal fossa by the temporalis muscle. There may be tenderness over the anterior part of the ramus and hematoma. Painful limitation of movement, especially on protrusion of mandible may be found.

Middle Third Fractures

Classification

- *Central middle third fracture*
 - *Le Fort's type-I*—bilateral detachment of the alveolar process and palate or the low level subzygomatic fracture of Guerin.
 - *Le Fort's type-II*—pyramidal subzygomatic fracture of the maxilla.
 - *Le Fort's type-III*—high level suprazygomatic fracture of central and lateral part of face.
- *Fracture of zygomatic complex*
 - Zygoma depressed with fracture at several sites
 - Fracture of zygomatic arch
- *Fracture of naso-ethmoidal complex*
- *Fracture of orbit*
 - Fracture of orbital rim
 - Orbital blow out fracture

Midfacial fracture

It may involve the frontal, nasal, lacrimal, zygoma, ethmoidal and sphenoid bones. They are classified by Rene Le Fort.

Le Fort I

It is also known as low level fracture/Horizontal fracture of Maxilla/Guerin fracture/Floating fracture.

- Horizontal fracture above the level of Nasal floor (**Fig. 28-29**).

Fig. 28-29: Diagrammatic representation of Le Fort I fracture.

- Fracture line extends backward from the lateral margin of the anterior nasal aperture below the zygomatic buttress to cross the lower 3rd of the pterygoid lamina.
- Fracture also passes along the lateral wall of the nose and the lower 3rd of nasal septum to join the lateral fracture behind the tuberosity.

Le Fort II

It is also called as 'Pyramidal or Subzygomatic fracture'. There is a pyramidal appearance of fracture in PA skull view (Fig. 28-30).

- This fracture runs from the thin middle area of the Nasal Bones down to either side crossing the frontal processes of maxilla into the medial wall of each orbit.
- Within each orbit, the fracture line crosses the lacrimal bone behind the lacrimal sac before turning forward to cross the infraorbital margin slightly medial to or through the infraorbital foramen.
- The fracture line now extends downwards and backwards across the lateral wall of the antrum below zygomatico-maxillary suture and divides the pterygoid laminae about halfway up. Separation of block from the base of skull is completed via the nasal septum and may involve the floor of the anterior cranial fossa.

Fig. 28-30: Le Fort II fracture—A diagrammatic representation.

Le Fort III

It is also called as 'High transverse or Suprazygomatic fracture'. It completely separates the middle third of the facial skeleton from the cranium (Fig. 28-31).

- The fracture line runs from near the frontonasal suture transversely, parallel with the base of the skull and involves the full depth of the ethmoid bone, including the cribriform plate.
- Within the orbit, the fracture line passes below the optic foramen into the posterior limit of the inferior orbital fissure.

- From the base of inferior orbital fissure, the fracture line extends into two directions:
 - Backwards across the pterygomaxillary fissure to fracture line the root of the pterygoid laminae.
 - Laterally across the lateral wall of the orbit separating the zygomatic bone from the frontal bone.

Fig. 28-31: Le Fort III fracture—A diagrammatic representation.

Clinical Features

Le Fort I

- **Location**—it may be unilateral or bilateral.
- **Symptoms**—in recent injury, there may be slight swelling of upper lip. Some fractures are so mobile that the patient has to keep the mouth slightly open to accommodate the increased vertical dimension of bite. Paresthesia presents over the distribution of infra-orbital nerve and pain over nose and face.
- **Signs**—ecchymosis is present in the buccal sulcus beneath the zygomatic arch. Occlusion is disturbed and variable amount of mobility may be found in the tooth bearing segment of maxilla. If the fracture line is at high level, the fragment will include the pterygoid muscle attachment. It will pull the fragment posteriorly and depress its posterior margin. Due to this, posterior maxillary teeth will force the mandible open resulting in open bite, retruded chin and long face.
- **Cracked pot sound**—in impacted type of fracture, there may be damage to cusps of individual teeth caused by impaction of the mandibular teeth against them. Percussion of upper teeth results in a distinctive 'Cracked pot' sound.
- **Flattening of face**—in some cases, there is flattening of middle of the face and epistaxis.
- **Palpation**—manipulation will reveal mobile maxilla and crepitation.

Le Fort II

- **Moon face appearance**—there is massive edema that causes marked swelling of the middle third of face giving rise to 'moon face' appearance.

- **Hemorrhage**
 - *Bilateral circumorbital ecchymosis*—ecchymosis about the eye which develops within minutes of injury (**Fig. 28-32**).
 - *Subconjunctival ecchymosis*—the conjunctivae over the inner quadrant of eye are blood shot and if the zygomatic bone is involved, this subconjunctival ecchymosis will also be over the outer quadrant.
 - *Periorbital hematoma*—it causes swollen conjunctiva to bulge out from between the eyelids.

Fig. 28-32: Circumorbital edema seen in maxillary fracture.

- **Eye**—there may be variation in the size of pupil which may occur due to peripheral damage to the oculomotor nerve. There may be diplopia and ocular movements may be limited.
- **Nose**—there may be lengthening of the nose. There may be bleeding from the nose.
- **Face**—there is 'dish-face' deformity of the face with occasional lengthening of the face.
- **Nerve damage**—as the fracture line passes across the inferior orbital rim, there may be injury to the infraorbital nerve resulting in anesthesia or paresthesia of cheek.
- **Step deformity**—there is step deformity at infraorbital margin. By applying the pressure between the bridge of the nose and the palate, pyramid of bone can be moved.
- **Cerebrospinal fluid rhinorrhea**—it is sometimes appreciated by salty taste in the mouth.
- **Intraoral finding**—retropositioning of the maxilla, so that anterior teeth do not meet and there is gagging on the posterior teeth. There is mobility of the upper jaw. Occasional hematoma of palate, which will cause patient considerable discomfort. Cracked pot sound on tapping the upper teeth.

Le Fort III

- **Location**—superficially, it appears similar to Le Fort II but injury is much more severe. It is very unusual to find Le Fort III fracture occurring in isolation.

- **Edema**—it is more extensive and massive.
- **Signs**—there is tenderness and often separation at the frontozygomatic sutures. The facial skeleton will be tilted to the side opposite to the direction of the fracturing force. There may be mobility of whole of the facial skeleton as a single block.
- **Nose**—nose often blocked with blood clot. There may be cerebrospinal fluid (rhinorrhea). There may be lengthening of nose.
- **Cerebrospinal fluid rhinorrhea**—it will be profused as compared to Le Fort II.
- **Hooding of eye**—there is lowering of the ocular level, due to the fracture line passing above the Whitnall's tubercle, removing the support given to the eye by Lockwood's suspensory ligament. As one or both eye drops, the upper lid follows the globe down, producing unilateral or bilateral 'hooding' of the eyes.
- **Hemorrhage**—bleeding into periorbital tissues.
- **Face**—there is separation of both frontozygomatic sutures which produces lengthening of face.
- **Step deformity**—flattening and step deformity at infraorbital margin.
- **Intraoral findings**—the entire occlusal plane may drop producing anterior open bite. There is gagging of occlusion in the molar area.

Radiographic Features

- **Le Fort I**—it is identified on PA, lateral skull and Water's projection (**Fig. 28-33**). Both the maxillary sinuses are cloudy and may show air filled level. Lateral view shows slight posterior displacement of fragment.

Fig. 28-33: Water's view showing Le Fort I fracture with fracture of zygomatic bone.

- *Le Fort II*—it will reveal the fracture of the nasal bone and both, frontal processes of maxilla and infra-orbital rims on both sides or separation of zygomatic sutures on both sides. Deformities and discontinuation of lateral walls of both sides of maxillary sinus (**Fig. 28-34**). There is thickening of the lining mucosa and clouding of maxillary sinus.
- *Le Fort III*—hazy appearance due to soft tissue swelling. Separation of sutures, i.e. of nasofrontal process, maxillofrontal, zygomatico-frontal and zygomatico-temporal. Nasal bone, frontal process of maxilla, both orbital floors and pterygoid plate show radiolucent lines and discontinuity. Ethmoidal and sphenoid sinuses are cloudy.

Fig. 28-34: CT scan showing the fracture at anterior and posterior wall of maxillary sinus.

Management

- *LeFort I*—Low level—intermaxillary fixation. High level—intermaxillary fixation and cranio-maxillary fixation.
- *LeFort II*—reduction followed by intermaxillary fixation. Open reduction and inter-osseous wiring of infraorbital rims. Antibiotics should be given to the patient.
- *LeFort III*—control hemorrhage and maintain airway. Surgery should be delayed until edema subsides. External immobilization should be done.

Zygomaticomaxillary Complex Fracture

The most common causes of ZMC fractures include interpersonal altercations, falls, motor vehicle accidents, and sports injuries. 25% of patients have other associated facial fractures (**Fig. 28-35**).

Classification

- *Class I*—Fracture of zygomatic bone with minimum or no displacement.

Fig. 28-35: Extensive soft tissue injury associated with fracture of zygomaticomaxillary complex.

- *Class II*—Fracture of zygomatic bone with displacement.
 - *Type A*—Rotation around a vertical axis
 - Inversion of the orbital ring
 - Eversion of the orbital ring
 - *Type B*—Rotation around a longitudinal axis
 - Medial displacement of frontal process
 - Lateral displacement of frontal process
- *Class III*—Enbloc displacement of the bone
 - Medial displacement
 - Inferior displacement
 - Lateral displacement
- *Class IV*—Comminution of the zygomatic bone
- *Class V*—Fracture of zygomatic arch alone

Clinical Features

- *Sign*—flattening of the cheek, swelling of the cheek, periorbital hematoma, subconjunctival hemorrhage (**Fig. 28-36**) and limitations of ocular movements, diplopia, ecchymosis and tenderness intraorally over zygomatic buttress, enophthalmos.
- *Symptoms*—lowering of pupil level, tenderness over orbital rim and frontozygomatic suture, epistaxis. Limitations of mandibular movements. Anesthesia of cheek, temple, upper teeth and gingiva. Possible gagging of back teeth on injured side.
- *Others*—step deformity of infraorbital margin. Separation of frontozygomatic suture.

Radiological Features

- Traditional facial radiographs like submentovertex view offers excellent resolution of the zygomatic arches (**Fig. 28-37**).

Fig. 28-36: Subconjunctival hemorrhage seen in Zygomatico-maxillary complex fracture.

Fig. 28-37: Zygomatic arch fracture.

Fig. 28-38: Water's view showing the fractured zygoma.

Fig. 28-39: CT scan, axial section showing the fracture of the anterior wall of maxillary sinus.

Fig. 28-40: CT scan coronal section showing the lateral displacement of fractured zygomatic bone fragment.

- Other views like Towne's, Water's and the AP views also offer significant information. The occipitontal or Water's view provide good visualization of whole of the zygoma and the maxillary sinus (**Fig. 28-38**).
- CT scans are considered as the standard criteria for the diagnosis of ZMC fractures. The CT scan helps the surgeon to make a more accurate preoperative diagnosis and helps to formulate a treatment plan (**Figs 28-39 and 28-40**).

Management

- **Reduction**—the treatment objective of the management of the zygomaticomaxillary complex fracture is to restore the premorbid malar and orbital configuration. The fracture of the arch and zygoma may be reduced through intraoral or extraoral approach. Three-point reduction is necessary for proper anatomic alignment of the pyramid—shape malar fragment in all planes and adequate fixation must be followed to keep the alignment stable. When there is minimum displacement of the zygomatic bone or arch, no cosmetic deformity or impairment of the eye movement no treatment may be required (**Fig. 28-41**).

Fig. 28-41: Postoperative radiograph of the patient of zygomatic fracture.

- **Open reduction**—the indications for the open reduction of the zygomaticomaxillary complex fracture are orbital deformities causing ocular disturbance, diplopia, facial asymmetry, multifragmentation and trismus.

Radiological Differential Diagnosis of Fractures of Maxilla

- **Infraorbital foramina**—it often leads to difficulty in diagnosing maxillary fracture when there is a history of blow. The foramen is situated sufficiently below the margin of orbit to form continuous line of bone between the orbit and margin of the foramen. But sometimes, the shadow of the actual canal is thrown over inferior orbital margin and this dark line suggests that a fracture is present. But, continuity of margin can be traced.
- **Suture line between malar bone and maxilla**—in PA view, there is often a thin dark line on the outer wall of antrum, vertical in direction and situated where the inferior margin of the malar bones joins the facial bone. It

represents suture line between the malar bone and maxilla. But in it, there is a thin white line on each side of the dark one and these represent the cortex of the suture.

- **Normal vascular channels**—in intraoral periapical (IOPA) radiograph of the posterior teeth, thin dark lines are often seen in the antral shadows. These represent the normal vascular channels and must not be mistaken for fracture. They all show thin white borders which the fractures do not.
- **Lip line**—in the upper cuspid region, lip line can lead to confusion for fracture line. The lip is retracted at the time that the radiographs are made, adding an extra thickness of tissue in the region where the lip is superimposed.

Greenstick Fracture

It occurs in young people. Rare in maxilla and mandible. Radiologically, there is sharp angulation present at the site of fracture. There may be one or more linear dark streaks running some distance along the length of the bones from each side of the angulation. Small spicules of bone may be seen standing away from the surface, which had been stripped away at the time of fracture.

Nasoethmoidal Injuries

An area behind which lies the interorbital space, which is situated between the medial walls of orbits (**Fig. 28-42**). Fractures in this region are invariably comminuted.

Fig. 28-42: CT scan showing fracture of nasoethmoidal fracture.

Classification

Isolated nasoethmoidal injury

- *Bilateral*—central midface injury resulting from direct blow over nasal bridge. Base of nose is driven backwards into interorbital space and nasal tip becomes upturned. Deep crease at base of nose and skin at base of nose frequently lacerated. CSF rhinorrhea should always be suspected.
- *Unilateral*—unilateral nasal deformity. Side of nose is depressed and there is underlying fracture of ethmoid bone.

Combined nasoethmoidal injury plus midface fractures

- *Bilateral*—nasoethmoid complex fracture combined with Le Fort II and Le Fort III fractures. Causes traumatic telecanthus and elongation of midface.
- *Unilateral*—nasoethmoid complex injury plus severe comminution of orbit and zygomatic complex. Unilateral displacement of medial canthal ligament resulting in displacement of eye downwards and laterally.

Clinical Features

It includes frontal bone depression, nasal deformity, traumatic telecanthus, CSF fluid rhinorrhea, diplopia, and hemorrhage from anterior or posterior branches of ethmoidal artery.

Management

- *Closed reduction*—the use of transnasal wires and compression plates is often unsatisfactory.
- *Open reduction*—realignment of bony fragments under direct vision especially at early stages gives better results.
- *Repair of bony skeleton*—Nasal bridge re-attached to frontal bone. All bone fragments must be preserved, aligned and either directly wired or plated with micro plates.

Complications of Healing

In Fracture

- *Non-union*—it results when callus of osteogenic tissue, over each of the two fragments, fails to meet and fuse or when endosteal formation of bone is inadequate. It can occur due to infection of the fracture site, inadequate immobilization and unsatisfactory apposition of bone. Radiograph shows rounding off and sclerosis of the bone ends, a condition known as 'eburnation'. It is common in elderly patients.
- *Fibrous union*—it occurs as a result of lack of immobilization of the damaged bone. The fractured ends united

by fibrous tissue but there is failure of ossification. They may produce pseudoarthrosis.

- *Lack of calcification*—it occurs in dietary deficiency or mineral imbalance.

In Extraction

Dry Socket

It is also called as 'Alveolitis sicca dolorosa', 'Alveolagia or Postoperative osteitis'. It is basically focal osteomyelitis in which blood clot has disintegrated or is lost. It is called as dry socket as after the clot is lost, the socket gives dry appearance because of exposed bone.

Etiology

- *Difficult extraction*—difficult or traumatic extraction, usually removal of impacted mandibular 3rd molars.
- *Dislodgement of clot*—dislodgment and disintegration of the clot and subsequent infection of the bone.

Clinical Features

- *Duration of occurrence*—it is the most common complication in healing of extraction wound. It arises within the first few days after extraction.
- *Symptoms*—it is extremely painful and odor is foul, but with no suppuration.
- *Signs*—exposed bone is necrotic and sequestration of fragments is common.
- *Healing*—healing of such infected wounds is extremely slow.

Prevention

- *Experiment by placing sulfanilamide*—sulfathiazole cones placed in fresh tooth socket of dog can prevent the occurrence of dry socket but it will cause retarded blood clot formation and even cause some breakdown of clot and remarkable delay in epithelialization.
- *Oxidase cellulose*—inserted for hemostatic purpose, produces retardation of healing similar to that of combined sulfonamide.
- *Sulfathiazole* in 60% glycerin base reduces the frequency of occurrence of dry socket.
- *Aureomycin*—causes significant reduction in decomposition of blood clot. There is decreased incidence of postoperative pain and swelling after one week.
- *Tetracycline hydrochloride*—if tablet is placed in extraction sockets, it helps in reduction of dry socket to 0.78%.
- *Trypsin*—digests necrotic tissue and debris and restrains bacterial growth.
- *Antiseptic mouth rinses*—use phenolated antiseptic mouth-rinses prior to extraction.
- *Little trauma*—one should try to cause a little trauma to tissue as possible. So that it helps in normal healing.

- *Myospherulosis*—it is the complication of healing of an extraction wound or soft tissue wound into which there is placement of antibiotic ointment with petroleum base. It results in formation of clear spaces within the area of healing and the presence of altered erythrocytes which assume the appearance of solitary or clusters of spherules that have been mistaken for large microorganism.

Management

- *Packing material*—insertion of packing material containing an obtundent.
- *Zinc oxide and eugenol pack*—iodoform gauze with zinc oxide and eugenol.

In Wound

Fibrous Healing of a Wound

It is an uncommon complication following a difficult, complicated or surgical extraction of tooth. It occurs most frequently when tooth extraction is accompanied by loss of both, lingual and labial cortical plates of bone with accompanied loss of periosteum.

It is usually asymptomatic and discovered only on radiological examination. Radiologically, it appears as a well circumscribed radiolucent area at the site of extraction wound.

Excision of the lesion for the purpose of establishing the diagnosis and to produce normal healing with subsequent bony repair.

Definition

The deposition of calcium salts, primarily calcium phosphate usually occurs in the skeleton. When it occurs in unorganized fashion in soft tissue, it is referred to as *Heterotopic calcification*.

Classification of Calcification

- *Dystrophic calcification*
 - General dystrophic calcification of the oral regions
 - Calcified lymph nodes
 - Dystrophic calcification in the tonsil
 - Cysticercosis
 - Calcified carotid artery
- *Idiopathic calcification*
 - Sialoliths
 - Phleboliths
- *Metastatic calcification*
 - Ossification of the stylohyoid ligament
 - Osteoma cutis
 - Myositis ossificans.

Dystrophic Calcification

General Dystrophic Calcification of the Oral Region

When calcium salt precipitate into primary site of chronic inflammatory dead and dying tissue, it is called as dystrophic calcification. It is associated with high local concentration of phosphatase, as in normal bone calcification and with anoxic conditions within the devitalized tissue.

Clinical Features

- *Location*—it is most frequent form of pathologic calcification and found in a wide variety of tissues like areas of tuberculosis, necrosis, and blood vessels in arteriosclerosis, scars and areas of fatty degeneration. In oral cavity, area of dystrophic degeneration is found in the gingiva, tongue or cheek.
- *Symptoms*—it is asymptomatic.
- *Signs*—overlying tissue is enlarged and ulcerated and solid mass of calcium salt palpable.

Radiographic Features

- *Site*—the common sites are long standing and chronically inflamed cyst.
- *Appearance*—appear as fine grains of radiopacities which are sparse and diffuse (**Fig. 29-1**).

Fig. 29-1: Dystrophic calcification seen superimposed on ramus of mandible (Courtesy Dr Parate).

- **Size**—may be single or multiple and rarely exceed 0.5 cm in diameter.
- **Margins**—outline is irregular or indistinct.

Calcified Lymph Nodes

These are types of dystrophic calcification that occurs in lymph nodes following chronic infections. Lymph node calcification is uncommon, and usually results from a previous granulomatous disease.

Causes

- *Tuberculosis lymphadenitis*—tuberculous lymphadenitis is probably a disease in which calcified lymph nodes occur.
- *Other diseases*—actinomycosis, histoplasmosis, cat-scratch fever and other chronic inflammatory diseases may also present calcified lymph nodes.

Clinical Features

- **Site**—nodes involved are submandibular or cervical chain.
- **Symptoms**—it is usually asymptomatic.
- **Number**—it may be single or multiple or sometimes chain of nodes.
- **Size and shape**—they are hard, round or oblong masses. Outline is well contoured and well defined.
- **Fixity to underlying tissue**—they are mobile during palpation.

Radiographic Features

- **Site**—it is most commonly seen behind or below the angle of the mandible (**Fig. 29-2A**). In some cases, it is seen in more inferior location when cervical lymph nodes are involved (**Fig. 29-2B**). In rare cases, calcified node is found posterior to the ramus.
- **Radiodensity**—it is opaque and well defined. In some cases radiodensity is variable showing both opaque and radiolucent appearance.
- **Appearance**—it may have laminated appearance. Radiopacity often exhibits a patchy pattern with a reticular arrangement of radiolucent lines or gaps.
- **Mass of coral appearance**—sometimes, irregular heterogeneous opaque masses are seen which appear to resemble a mass of coral.
- **Margins**—well defined and usually irregular, occasionally having a lobulated appearance similar to outer shape of cauliflower.

Diagnosis

- **Clinical diagnosis**—it is not possible to make clinical diagnosis.

Figs 29-2A and B: Calcified lymph nodes, cervical lymph nodes that is cauliflower shaped and chainlike (Courtesy Dr Enzo Rovigatti).

- **Radiological diagnosis**—mass of coral appearance and in some cases, laminated appearance.

Differential Diagnosis

- *Sialoliths*—it is painful and has a smooth outline whereas calcified lymph nodes are usually irregular and sometimes lobulated.
- *Phleboliths*—they are smaller and have concentric radiopaque and radiolucent rings.

Management

- **Surgical removal**—large calcified lymph nodes should be surgically removed.

Tonsillolithiasis

It is dystrophic calcification in the tonsil. It is also called as 'Tonsillar calculi', 'Tonsil concretions', and 'Tonsilloliths'. The mechanism is similar to that of calcified lymph nodes. It occurs due to recurrent inflammation of tonsil.

Clinical Features

- **Age and sex distribution**—it is common in older age groups between 20 to 68 years of age. Women are more commonly affected.
- **Location**—it can be unilateral or bilateral.

- *Symptoms*—small calcification produce no symptoms but larger calcification can produce pain, swelling and dysphagia.
- *Recurrent tonsillitis*—it is also common feature of tonsillar calculi.
- *Palpation*—there is hard, yellow submucosal mass of the affected tonsil.

Radiographic Features

- *Site*—it is seen in middle portion of the mandibular ramus in the region where the image of the dorsal surface of tongue crosses the ramus.
- *Appearance*—it can produce 'speckled' appearances of multiple radiopaque superimposed bilaterally on the images of the mandibular rami in a panoramic radiograph.
- *Size*—it may reach the size of 0.5 cm to 14.5 cm.
- *Margins*—multiple small ill defined radiopacities are seen.
- *Internal structure*—it appears more radiopaque than the cancellous bone and same as cortical bone (Fig. 29-3).

Fig. 29-3: Tonsillitis is present (red arrow) on CT scan (Courtesy RS Kamikawa).

Diagnosis

- *Clinical diagnosis*—recurrent tonsillitis is common features
- *Radiological diagnosis*—speckled appearance with multiple radiopaque image on ramus area.

Differential Diagnosis

- *Radiopaque lesion in mandibular ramus*—in it right angle view such as PA skull or open Towne's view may show that calcification lies to the medial aspect of the ramus.

Management

- *Enucleation*—larger calcifications with associated symptoms are removed surgically.

Cysticercosis

When eggs or gravid proglottids from *Taenia sodium* (pork tapeworm) are ingested by human, their covering is digested in stomach and larval form (*Cysticercus cellulosae*) of the parasite is hatched. Larvae penetrate the mucosa, enter the blood vessels and lymphatics and are distributed in the tissue all over the body. After the larva die, the larval spaces are replaced with fibrous connective tissue, which may become calcified.

Clinical Features

- *Mild cases*—they are completely asymptomatic.
- *Severe cases*—there is mild to severe GIT upset with epigastric pain, severe nausea and vomiting.
- *Nervous system*—convulsion, irritability and loss of consciousness.
- *Size*—palpable firm mass upto 1 cm in diameter.
- *Oral finding*—multiple small nodules may be felt in the region of masseter and suprahyoid muscles and in buccal mucosa or lip.

Radiographic Features

- *Site*—the muscle of mastication and facial expression, the suprahyoid muscle and the postcervical musculature.
- *Margins*—the margins are well defined.
- *Shape*—the shape is elongated, elliptical or ovoid.
- *Internal structure*—it is homogenous and radiopaque.

Diagnosis

- *Clinical diagnosis*—Gastrointestinal problems are present. Small nodules seen in masseter region will give clue to the diagnosis.
- *Radiological diagnosis*—homogenous radiopaque mass is present.

Differential Diagnosis

- *Salivary stone*—it is not multiple as compared to cysticerci.

Management

- *Medical management*—medical management by the physician.

Calcified Carotid Artery

It is also called as 'atheroma'. Arterial wall may calcify in all forms of arteriosclerosis with deposition of calcium salts within the medial coat of the vessels.

Causes

- *Inflammatory process*—it is sequelae of inflammatory process affecting the wall.
- *Other causes*—it is also found in Sturge-Webber syndrome and diabetes mellitus.

Clinical Features

- Usually no clinical sign or symptoms develop.

Radiographic Features

- *Site*—calcification with the carotid artery are located in the soft tissue below the angle of the mandible and between the hyoid bone and the image of the cervical spine (**Figs 29-4A and B**).
- *Margins*—calcific deposits on wall of artery will outline the image of the artery.

Figs 29-4A and B: OPG showing calcification in the carotid artery (Courtesy Dr Fábio de Lima Cravo).

- *Appearance*—a pair of thin opaque lines that may have either a straight course or a tortuous path. They may appear as amorphous or punctuate calcifications.
- *Internal structure*—the calcified wall appear as radiopaque circle.
- *Stroke*—in patient who is suffering from diabetes mellitus and having calcification in the region of carotid artery leading to macrovascular atherosclerosis can cause stroke.

Diagnosis

- *Clinical diagnosis*—it is not possible to make clinical diagnosis.
- *Radiological diagnosis*—calcified deposit seen on walls of artery.

Differential Diagnosis

- *Other calcific deposits*—usually, the linear nature of the calcified arterial wall indicates the nature of this condition.

Management

- This disease requires no treatment. Only special care should be taken for stroke.

Idiopathic Calcification

The deposition of calcium in normal tissue despite normal serum calcium and phosphate level is referred to as 'Idiopathic calcification'.

Sialoliths

It is described in Chapter 26: Salivary Gland Disorders.

Phleboliths

These are thought to be formed in older thrombi in veins or hemangiomas with slow blood flow. The thrombus organizes into granulation tissue and occasionally mineralizes with the deposition of calcium phosphate and calcium carbonate.

Clinical Features

- *Appearance*—the involved soft tissue may be swollen or discolored by the presence of veins or a soft tissue hemangioma.
- *Pressure application*—applying pressure to the involved tissue should cause a blanching or change in color if the lesion is vascular in nature.

Radiological Features

- **Site**—they are most commonly found in the hemangiomas.
- **Margins and shape**—the shape is round or oval with a smooth periphery. If it is viewed from side resembles a straight or slightly curved sausage.
- **Internal structure**—it may be homogeneously radiopaque but more commonly has a appearance of laminations. A radiolucent center seen, which may represent the remaining patent portion of the vessels (**Fig. 29-5**).

Fig. 29-5: Phleboliths showing multiple oval radiopacities (Courtesy RS Kamikawa).

Diagnosis

- **Clinical diagnosis**—swelling swollen tissue over the vein may suspect the disease.
- **Radiological diagnosis**—round shaped radiopacity with radiolucent center will give clue to the diagnosis.

Differential Diagnosis

- **Sialoliths**—sialoliths occur single as compared to phleboliths which is usually multiple.

Management

- Treatment of underlying cause should be done.

Metastatic Calcification

In this, calcium salts are precipitated in previous undamaged tissue. This precipitation is due to an excess of blood calcium and occurs particularly in such diseases as hyperthyroidism which depletes the bone calcium and causes a high level of blood calcium. The deposits of calcium occur in the kidney, lungs, gastric mucosa and media of blood vessels.

Ossification of the Stylohyoid Ligament

Ossification of stylohyoid is common and when it is associated with discomfort it is called as '*Eagle's syndrome*'. Ossification usually extends downward from the base of the skull and commonly occurs bilaterally. Bone tissue forms within segments of the stylohyoid ligament.

Clinical Features

- **Palpation**—there is hard pointed structure over the tonsil.
- **Symptoms**—vague pain on swallowing, turning the head and opening the mouth. Patient may describe earache, headache, dizziness or transient syncope which is caused by elongated styloid process impinging on glossopharyngeal nerve.
- **Signs**—there may be visible swelling on the region of the angle of mandible (**Fig. 29-6A**).
- **Stylohyoid syndrome**—clinical finding without the history of neck trauma constitutes '*Stylohyoid syndrome*'.

Fig. 29-6A: Swelling seen in angle of mandible region due to ossification of stylohyoid ligament.

Radiographic Features

- **Site**—styloid process appears as long, lapping, thin, radiopaque process between ramus of mandible and mastoid process. Ossification of ligament roughly parallels the posterior border of the ramus (**Fig. 29-6B**).
- **Appearance**—it appears as long, tapering, thin radiopaque process that is thicker at base and projects downward and forward.
- **Size**—it varies about 0.5 to 2.5 cm in length.
- **Internal structure**—small ossification appear homogeneously radiopaque. As the ossification increases in length and width, the outer cortex of its become evident as radiopaque band at the periphery.

Diagnosis

- *Clinical diagnosis*—earache, headache, dizziness with swelling at angle of mandible will suspect this disease.
- *Radiological diagnosis*—elongated stylohyoid process is easily identified on the radiograph (Fig. 29-6C).

Management

- *Amputation*—amputation of stylohyoid process should be carried out.

Fig. 29-6B: Calcified Outline of stylohyoid ligament (Courtesy RS Kamikawa).

Fig. 29-6C: Elongated styloid process with nodular mineralization pattern (Courtesy RS Kamikawa).

Osteoma Cutis

These are sites of normal bone formation in abnormal locations. The lesion occurs secondary to acne of long duration, developing in a scar or chronic inflammatory dermatosis.

Clinical Features

- *Site*—face is the most common site followed by lip (Fig. 29-7A) and tongue is the most common intraoral site.
- *Size*—size ranges from 0.1 mm to 5 cm and may be seen as single or multiple.
- *Color*—color may be normal or yellowish white.
- *Aspiration*—needle when inserted is met with stone-like resistance.

Fig. 29-7A: Osteoma cutis seen in lower lip region as slightly pale in color.

Radiographic Features

- *Site*—most commonly appears in the cheek and lip regions. Image can be superimposed over a tooth root or alveolar process.
- *Margins and shape*—smoothly outlined radiopaque washer-shaped image.
- *Size*—they are very small, although size can range from 0.1 to 5 cm.
- *Internal structure*—it may be homogenous radiopaque or may have a radiolucent center that represents normal fatty marrow.

Diagnosis

- *Clinical diagnosis*—There are areas of dense viable bone in the dermis or subcutaneous tissue.
- *Radiological diagnosis*—washer shaped image seen on the periapical radiograph (Figs 29-7B and C).

Differential Diagnosis

- *Myositis ossificans and calcinosis cutis*—osteoma cutis is more superficial than others.

Figs 29-7B and C: Multiple miliary osteoma cutis. Patient with history of large quantity of acne for a long period of time. Periapical radiographs showing evidence of ossifications in the soft tissues of the cheek (Courtesy RS Kamikawa).

Management

- **Surgical removal**—osteomas are occasionally removed for cosmetic reasons.

Myositis Ossificans

It is a condition in which fibrous tissue and heterotopic bone form within the interstitial tissue or muscle, as well as in associated tendons and ligaments. Secondary destruction and atrophy of the muscle occurs, as this fibrous tissue and bone interdigitate and separate the muscle fibers.

Types

- Localized myositis ossificans or traumatic myositis ossificans.
- Progressive myositis ossificans or generalized myositis ossificans.

Localized Myositis Ossificans

It is also called as 'Post-traumatic myositis ossificans' or 'Solitary myositis'.

Etiology

- **Trauma**—it is caused by acute or chronic trauma or heavy muscular strains caused by certain occupation or sports. Traumatization of the periosteum of an adjacent bone with the displacement of osteoblasts into the muscle and subsequent formation of bone.
- **Periosteal implants**—activation of periosteal implants already present in muscle by trauma or hemorrhage.
- **Metaplasia**—metaplasia of the pluripotential intermuscular connective tissue into the bone. Metaplasia of fibrocartilage.

Pathogenesis

- **Injury**—hemorrhage into the muscle or associated tendon or fascia → the hemorrhage organized and undergoes scarring → during healing process cartilage is formed → calcification of cartilage → ossification of cartilage.

Clinical Features

- **Age and sex**—it can occur at any age, sex and more often in young persons.
- **Site**—the most commonly involved muscles are the masseter and sternocleidomastoid but in some cases, lateral pterygoid muscle can be involved.
- **Symptoms**—site of trauma remains swollen, tender and painful much longer than expected. In some cases, there is a mild discomfort associated with a progressive limitation of motion.
- **Signs**—the overlying skin may be red and inflamed. Intramuscular mass is palpated at 2 to 3 weeks. The lesion may appear fixed or it may be freely movable on palpation.

Oral Manifestations

- **Site**—it involves the muscles of face particularly masseter and temporal following single traumatic injury.
- **Symptoms**—some difficulty in opening of the mouth.

Radiographic Features

- **Site**—radiolucent band can be seen between the area of ossification and adjacent bone and heterotopic bone may lie along the long axis of the muscle.
- **Internal structure**—faintly homogenous opacity. Delicate lacy or feathery internal structure of increased radio-density develop indicating bone has formed (**Fig. 29-8**). Sometimes it is accompanied by circumscribed cortical periphery.

Fig. 29-8: Myositis ossificans. See the increased radiodensity with margins are more radiopaque than internal structure (Courtesy Dr Bhaskar Patle).

- **Margins**—margins are more radiopaque than the internal structure.
- **Shape**—there is variation in shape from irregular oval to linear streaks running in the same direction as the normal muscle fibers. These *pseudotrabeculae* are characteristic of myositis ossificans and strongly imply a diagnosis.
- It lies close to the surface of the bone. With the passage of time the new bone is resorbed.

Diagnosis

- **Clinical diagnosis**—palpable intramuscular mass with swelling area of trauma may give clue to the diagnosis.
- **Radiological diagnosis**—pseudotrabeculae and more radiopaque margin is present.
- **Laboratory diagnosis**—biopsy shows degeneration of muscle and connective tissue hyperplasia to chondrification and ossification. The trabecular pattern is often extremely bizarre with the cartilage and myxomatous tissue present which may resemble callus formation.

Differential Diagnosis

- **Ossification of stylohyoid ligament, dystrophic calcification in areas of necrosis, pathological calcification and phlebitis**—the form and location of myositis ossificans are enough make the differential diagnosis.

Management

- **Rest**—sufficient rest should be given with limitation of use.
- **Excision**—excision after process becomes stationary.

Progressive Myositis Ossificans

It is characterized by formation of bone in tendons and fascia with subsequent replacement of adjacent muscle by expanded bony mass. In some cases, there is history of hereditary and familial pattern.

Clinical Features

- **Age and sex**—it usually affects children before 6 years of age. It is seen more in males as compared to females.
- **Progress**—it may advance rapidly or there may be long period of relative inactivity with intermittent bursts of activity.
- **Site**—starts in muscles of neck and upper back and moves to extremities.
- **Symptoms**—soft tissue swelling that is tender and painful and may show redness and heat.
- **Sign**—gradual increase in stiffness and limitation of motion of neck, chest and back and extremities. Ultimately entire groups of muscles become transformed into bone resulting in limitation of movements.
- **Associated anomalies**—it is associated with congenital small first metatarsal and metacarpal bones, small little bone. Interphalangeal joint may be fused.
- **Facial finding**—the masseter muscle is frequently involved so that fixation of jaw occurs.
- **Petrified man**—the patient becomes rigid and called as 'Petrified man'.
- **Prognosis**—patient dies during 3rd or 4th decades. Premature death is usually results from respiratory embarrassment.

Radiographic Features

- **Appearance**—there is evidence of dense osseous replacement of the greater part or whole of the muscle.
- **Internal structure**—densities of heterotrophic bone vary widely. The bone that is laid down in the muscle does not show structure of normal bone but it is rather structureless mass of variable density.
- **Linear striae of increase density**—coarse linear striae of increased density represent new bone formation in some cases; the streaks follow the long axis of the particular muscle involved. In early stages calcified deposits are granular and fragmentary.
- **Margins**—lesion have smooth or irregular margins, lying in close relationship with the bone.

- *Advanced lesion*—the dense masses with passage of time tend to coalesce. Skeleton becomes osteoporotic because of lack of function as muscles atrophy and joints become ankylosed.

Diagnosis

- *Clinical diagnosis*—‘Petrified man’ appearance with gradual limitation of movement of the body.
- *Radiological diagnosis*—bone in muscle show structureless mass of variable density.
- *Laboratory diagnosis*—the muscle in this disease is gradually replaced by connective tissue which undergoes osteoid formation and subsequently ossification. In some cases, cartilage formation may become evident.

Differential Diagnosis

- *Rheumatoid arthritis*—in initial stage, it is difficult but as disease progress specific anomalies confirms the diagnosis.
- *Calcinosis*—the deposits of amorphous calcium salts frequently resorb, but in progressive myositis ossificans the bone never disappear.

Management

- No effective treatment exists. Nodules that are traumatized and then ulcerated frequently should be excised.

Section **4**

Systemic Diseases Manifested in Jaw

Introduction

The literal meaning of the word 'disease' is 'loss of ease'. The oral cavity reflects the state of systemic health more frequently than other parts of the body. Even in ancient time, examination of mouth and tongue was given great importance. The oral tissues are in direct physical continuity with rest of the body and they are also related via blood, lymphatics and nerve pathways. Furthermore, systemic influence such as endocrinological, immunological and psychological factors has an important role in the balance between oral health and disease.

During both, development and maintenance, local and systemic factors are concerned in disease process of mouth. Oral health must be considered in relation to general health. The dentist's role in general health is based on the fact that, he is the first person to see the oral lesion. In preventive dentistry, the utmost principle is of early diagnosis. Dentist has an important role in preventive medicine as many systemic diseases have primary oral manifestations.

Infections Caused by Bacteria

The following diseases are caused by bacteria.

Syphilis

It is also called as 'lues'. The incidence of syphilis is decreased after introduction of penicillin in late 1940s. Patient infected with *Treponema pallidum* and HIV may exhibit a malignant form of syphilis with slow development of standard serological response to syphilis. The tertiary manifestations lead to considerable morbidity and mortality.

Etiology

- *Sexual contact*—it occurs most exclusively by venereal contact.
- *Maternal transmission*—infection may transfer from mother to fetus.
- *Drug user*—incidence of syphilis is increased nowadays in crack cocaine abuse and barter of illegal drugs for sex.
- *Predisposing factors*—overcrowded living and primitive housing conditions are the predisposing factors for syphilis.

Classification

- *Acquired syphilis*—contacted primarily as venereal disease due to sexual intercourse with infected partner.
 - *Primary*—it is evident clinically 3 to 90 days after the exposure.
 - *Secondary*—it is discovered 4 to 10 weeks after primary stage.
 - *Tertiary*—this stage develop after the latent phase.
 - *Quaternary syphilis*—the atypical malignant progression of tertiary neurosyphilis in immunocompromised HIV individuals is referred as quaternary syphilis.
- *Latent phase*—this appear after secondary stage and in this stage, there is no sign and symptoms are present. Serological test is positive in this stage.
- *Congenital*—this is secondary to fetal infection.
- *Early syphilis*—primary syphilis, secondary syphilis and the early latent phase of the disease are grouped as early syphilis. Early syphilis may last up to two years and is infectious.
- *Late syphilis*—while late latent and tertiary are grouped as late syphilis. Late syphilis is locally destructive and non-infectious.

Primary Syphilis

Clinical features

- **Incubation period**—lesion develop at the site of inoculation approximately 3 to 90 days after the inoculation.
- **Site**—it occurs most frequently on penis in males and vulva or cervix in females. Recently, occurrence on extragenital sites have increased as a result of increase in orogenital sex and increased contact among the infected homosexuals. Extragenital sites of involvement include fingers, perianal region, nipples, lips, tonsils and intraoral structures such as tongue and palate.
- **Chancre**—it is slightly raised, ulcerated, non-tender, non-bleeding, firm plaque which is usually round, indurated and with rolled raised edges.
- **Size**—it varies in size from 5 mm to several centimeters.
- **Symptoms**—it is painless, unless superinfected. It disappears without therapy after 10 days.
- **Lymph nodes**—regional lymph nodes become firm enlarged, rubbery in consistency and non-tender.

Oral manifestations

- **Site**—oral lesions of primary syphilis are rare and occur at the site of entry of treponema. Chancre has been described on lips, oral mucosa, lateral surface of tongue, soft palate, tonsillar area, pharyngeal area and gingiva.
- **Transmission**—transmission can occur during kissing as a consequence of sexual practice among homosexual and heterosexuals, or by contact with objects such as mouth piece of musical instruments and medical or dental instruments.
- **Appearance**—it has narrow copper colored, slightly raised borders with reddish brown base in center.
- **Symptoms**—intraoral chancres are slightly painful due to secondary infection and are covered with grayish white film.
- **Size**—it measures from 0.5 to 2 cm in diameter.
- **Signs**—occasionally, it retains white sloughy material. In some cases, there is proliferation that resembles pyogenic granuloma.
- **Tonsils**—primary involvement of tonsils is manifested by considerable edema, redness, ulcerated and eroded lesion.
- **Lymph nodes**—regional lymphadenopathy occurs.
- **Extraoral lip chancre**—extraoral lip chancre may have more typical brown crusted appearance which may be multiple. Lower lip involved more frequently (**Fig. 30-1**).
- **Healing**—oral chancre heals spontaneously in 3 to 8 weeks leaving small scars.

Secondary Syphilis

Clinical features

- **Spread**—organisms proliferate and spread by the way of bloodstream to produce lesions elsewhere.

Fig. 30-1: Chancre present on the lower lip in male patient which has got slightly raised border (Courtesy Dr Jitu Sachdeo).

- **Incubation period**—it usually appears within 4 to 10 weeks after primary lesion.
- **Symptoms**—fever and generalized lymphadenopathy, which is painless, discrete and non-adherent to the surrounding tissues, may be seen. Headache, anorexia, pain in joints and muscles also occurs.
- **Skin**—when appear on skin, they manifest as fine macular or papular rash, sometimes accompanied by alopecia. The skin rash may resolve completely or leave residual areas of hypo- or hyperpigmentation.
- **Face**—circinate lesions on face are characteristic of secondary syphilis.
- **Mucus patches**—mucus patches are small, smooth, erythematous areas or superficial grayish erosions found on mucus membrane of vulva, penis, or in oral cavity, on palate and tonsils. They are described as snail track ulcers.
- **Condyloma latum**—condyloma latum are grayish, moist, flat topped, extra large plaque which sometimes coalesce into larger plaques, found on moist mucocutaneous surfaces such as vulva, anus, scrotum, thigh and axilla.
- **Split papule**—split papule is a double papule which occurs at skin folds and angle of mouth.
- **Lues maligna**—this is explosive and widespread form occurs in compromised immune system. It is characterized by formation of necrotic ulceration.
- **Lymph nodes**—generalized symmetrical enlargement of the lymph nodes in posterior cervical, suboccipital, supratrochlear and inguinal regions.
- **Latent phase**—patient may enter the phase of latency without treatment.

Oral manifestations

- **Mucus patches**—it is mucous membrane analogue of papular or macular skin eruptions.
 - **Site**—it is found on tongue, buccal mucosa, tonsillar and pharyngeal region, and lips.

- *Appearance*—it appears as slightly raised grayish white lesions surrounded by erythematous base.
- *Surface*—they are covered by grayish white membrane. Trauma results in raw bleeding surface.
- *Snail track ulcers*—confluence and coalescence of these glistening mucous patches gives rise to the so called 'snail track ulcers'.
- *Symptoms*—it is often painless but mild to moderately painful.
- *Split papule*—they are highly infectious.
 - *Site*—split papule is a raised papular lesion developed at the commissure of lip and with a fissure separating the upper lip portion from lower lip portion.
 - *Appearance*—they are called as split papules as they are cracked in the middle giving a 'split pea appearance'.
- *Condyloma latum*—they are flat silver gray wart like papule, sometimes having ulcerated surface. They are painless. Regional lymphadenopathy is usually present.

Tertiary Syphilis

Clinical features

- *Incubation period*—it may occur at any age from the third year upto the patient's life.
- *Forms*—in tertiary syphilis, 1/3rd develop benign or gummatous form, 1/3rd cardiovascular form and 1/3rd neurosyphilis, i.e. general paresis and tabes dorsalis.
- *Gumma*—gumma is due to a chronic destructive granulomatous process which occurs anywhere in the body. Gumma is the result of hypersensitivity reaction between hyperergic host and treponema. Single cerebral gumma may produce symptoms suggestive of brain tumor
 - *Types*—there are two types of gumma, i.e. central and cortical.
 - *Appearance*—the characteristic gumma appear as chronic granulomatous localized lesion, which ulcerates. It is nodular in appearance.
 - *Signs*—punched out ulcer with vertical walls and dull red granulomatous base is the typical clinical feature of ulcerative gummatous lesion.
 - *Cutaneous lesions*—cutaneous lesions heal slowly and leave behind tissue paper-like scars.
- *Neurosyphilis*—it occurs due to obliteration of small vessel artery involving vasa vasorum of aorta and other large vessels of the central nervous system (neurosyphilis). Neurosyphilis is manifested as tabes dorsalis and general paresis. Tabes dorsalis is the syphilitic involvement of dorsal column of spinal cord and dorsal root ganglion. General paresis is syphilitic involvement of cerebral tissue.
- *Tabes dorsalis*
 - *Symptoms*—patient loses the positional sense of his lower extremities and walks with a slapping step. Burning and pricking sensation of the extremities, paresthesia, or actual anesthesia of the part may accompany the characteristic gait.
 - *Positive Romberg's sign*—person is unable to stand erect unaided with his eyes closed.
 - *Tabetic crises*—short, shooting, knife-like pains may be experienced in the abdominal region called 'tabetic crises', which results from involvement of the dorsal root ganglion.
 - *Charcot's joint*—trophic changes consist of deep perforating ulcers and painless destruction of larger joints.
- *General paresis*
 - *Argyll Robertson pupil*—pupils that react to accommodation but not to light.
 - *Symptoms*—increased irritability, fatigue, mental sluggishness and carelessness in personal habits.
 - *Signs*—loss of fine muscular coordination is indicated by inability to enunciate clearly or to perform delicate tasks with the hands.
 - *Spinal cord involvement*—involvement of spinal cord is late manifestation characterized by paresthesia, burning and prickling sensation in the extremities.
 - Patient may get unrealistic ideas of wealth or ability.
- *Cardiovascular syphilis*—it occurs in 10% cases of late syphilis. Involvement of CVS in tertiary syphilis affects aorta and aortic valve and 80% of deaths occur due to it. There is medial necrosis and destruction of elastic tissue occurs in the wall of large blood vessels. Dilatation and aneurysm occurs.
- *Tertiary syphilis in HIV patient*—a recent feature has been an apparent alteration in the behavior of syphilis in HIV positive patients. Natural history of syphilis may be altered in HIV positive patients and this group is at high risk for the development of tertiary syphilis. Genital ulcerations due to syphilitic infection allows a portal of entry for the viral particles and may lead to greater risk of infections in these patients.

Oral manifestations

- *Site*—gumma can occur anywhere in the jaw but are more frequently on palate, mandible, and tongue.
- *Gumma*
 - *Appearance*—gumma may manifest as solitary, deep, punched out mucosal ulcer.
 - *Symptoms*—breathing and swallowing difficulty may be encountered by the patient.
 - *Progress*—it usually starts as small, pale, raised, nodular mass in the midline of the palate which ulcerates and rapidly progresses to the zone of necrosis.

- *Signs*—it may cause perforation of palatal vault.
- *Punch out defects*—lesion is sharply demarcated and the necrotic tissue at the base of the ulcer may slough away leaving punched-out defects.
- *Tongue*—numerous small healed gummata in tongue results in series of nodules or scars in deeper areas of the organ, giving the tongue an *upholstered or tufted appearance*.
- *Leutic glossitis*—complete atrophy of papillary coating and firm fibrous texture seen. It is called as leutic glossitis. Initially, it is thought to be precancerous but nowadays, this concept is disputed. Loss of papillae is probably due to endarteritis leading to circulatory deficiency of lingual vasculature.
- *Chronic superficial interstitial glossitis*—the tongue may involve diffusely with gumma and appear large, lobulated and irregularly shaped. This lobulated pattern is called as chronic superficial interstitial glossitis.

Radiographic Features of Syphilis

Bones are not known to be involved in the primary stage. Bone involvement usually occurs in tertiary stage and in some cases, in secondary stages.

Gummatous Lesion of the Bone

- *Site*—skull is one of the usual sites of gummatous involvement frequently involving frontal, parietal, and temporal bone. Maxilla is affected more than the mandible, the common site being the hard palate particularly the central portion. It begins as extension of gumma from the palatal mucosal aspect or from the floor of nose. Multiple gummas of oral structure may invade the coronoid process and medial pterygoid muscle.
- *Central gumma*—there is radiolucent area with ill-defined margins which merge with the normal bone or there are multiple areas of greater radiolucency. These areas are separated from one another by normal looking bone. With the passage of time, radiolucent areas are fused and appear as one dark shadow which is caused by perforation of the palate.
- *Cortical gumma*—it starts on the surface of bone and destroys a wide area of the cortical covering. The deeper cancellous bone is involved later and destroyed. The result is that there is a well-marked area of bone destruction, open to the surface of the bone and has sharply defined margins, which are devoid of rarefaction.
- *Diffuse gummatous infiltration*—it is usually found in the vault of the skull in the vicinity of the intramedullary gummata. Mandible is involved more often than maxilla. Suppuration and sequestration are always present. Radiographic appearance suggests widespread

osteomyelitis which has not been treated. There are many islands of bone with widely varying shape and size, many with grossly irregular borders, which are well defined. The density of the islands of bone varies from normal bone to rarefied bone.

Syphilitic Periostitis

It is the most common manifestation of congenital syphilis and may also be seen in secondary stage of acquired syphilis. The lesion may develop very late in the disease process and is characterized by periosteal reaction, which may either be limited and circumscribed or extensive.

- *Site*—it involves mandible more commonly and it appears as a single layer or several layers of new bone, more or less parallel with the margins of jaw. The calvarium is one of the usual sites of involvement in this manifestation of syphilis.
- *Network of lattice*—a rare manifestation of syphilitic periostitis is new bone arranged with trabeculae forming a loose type of pattern which is best described as a gross caricature of a network of lattice. There is often a dark line between the new bone and jaw and between the layers of new bone.
- *Syphilitic osteitis*—there are small superficial areas of rarefaction, in the underlying bone, due to syphilitic osteitis.

Congenital Syphilis

It is infection of fetus established by the passage of spirochetes from mother, through the placenta. Transplacental infection after 18-week gestation is related to development of immune complement rather than any toxic effect on organism.

Congenital syphilis has got three diagnostic features called as *Hutchinson's triad* which includes hypoplasia of permanent incisors and 1st permanent molars, eighth nerve deafness and interstitial keratitis.

Clinical features

- *Early manifestations*—it is manifested within the first 2 years of life (neonatal congenital syphilis) as rhinitis and chronic nasal discharge with maculopapular eruptions, other than mucocutaneous lesion and loss of weight. The lesions can be seen in spleen, kidney, bones and CNS. Bullae, vesicle and superficial desquamation with cracking and scaling of reddened soles and palms, petechiae, mucus patches and condyloma latum also occurs.
- *Late manifestations*—after 2 years, interstitial keratitis (opacification of corneal surface with resultant loss of vision), vascularization of cornea, eighth nerve deafness, arthropathy, signs of congenital neurosyphilis, gummatous destruction of palate and nasal septum develop. There are also saber shins or anterior tibial bowing.

- *Higoumenakis's sign*—irregular thickening of sterno-clavicular portion of clavicle.

Oral manifestations

- *Postrhagadic scarring and syphilitic rhagades*—post-rhagadic scars are linear lesions found around oral and anal orifices. They result from diffuse leucic involvement of the skin in these areas from 3rd to 7th week after birth. They appear as red or copper colored linear areas covered with a soft crust. Rhagades are said to be more frequent on the lower lip. Healed syphilitic rhagades appear as ordinary cicatrices.
- *Linear scars*—the linear scars are radially arranged and perpendicular to the mucocutaneous junction, which are more prominent on lower lip near angle of mouth.
- *Changes in dentition*—retarded root resorption of deciduous dentition. There may be 'marring' of permanent incisors present in congenital syphilis. 6 to 28% of the incisors and 3 to 37% of the molars have hypoplasia. Spacing between cuspid and incisors is present. Malocclusion and open bite is present.
- *Molar features*—the crown of the first molar in congenital syphilis is irregular and enamel of the occlusal surface and occlusal third of the tooth appears to be arranged in agglomerate mass of globules, rather than in well formed cusp.
- *Screw driver shaped incisors*—constriction of crown toward incisal edge screw results in driver or peg shaped incisor. In addition, incisal edge is usually notch which may be due to the absence of central tubercle or calcification center. Rounding of mesial and distal incisal line angles.
- *Moon molars*—in molars, positioning of the cusps toward the central portion of the crown, gives the tooth a bud shaped or a shrunken occlusal form called as mulberry molars or Moon's molars. Affected molars are dirty yellow in color due to hypocalcification.
- *Carabelli cusp*—prominent accessory mesiolingual cusp of upper molar (Carabelli cusp).
- *Jaw bones*—defective maxilla which is hypoplastic and short with relative mandibular prognathism. Frontal bossing and saddle nose deformity occurs.
- *Lesion biopsy*—histopathological examination of suspected lesion, stained by silver impregnation technique, is useful particularly when the lesion contains few organisms, as may be in case of tertiary lesion. For oral lesions, this technique is of considerable value.
- *Treponemal antigen test*—Treponemal test is of value in making a confirmatory diagnosis while non-treponemal test is of value in assessing the efficacy of the therapy.
- *Non-treponemal (antigen) test*—commonly used non-treponemal test is Venereal Disease Research Laboratory (VDRL) and rapid plasma reagin (RPR) test. Both tests are inexpensive, simple and rapid to perform but require competent experienced laboratory to minimize the risk of false positive or false negative results.

Management

- *Antibiotics*—patient should give benzathine penicillin (2.4 million units IM) aqueous crystalline penicillin, tetracycline hydrochloride (500 mg orally 4 times a day for 15 days). Patients who are allergic to penicillin erythromycin (500 mg by mouth 4 times a day for 15 days). *T pallidum* disappears from infectious lesion within 24 hours of instituting therapy.
- *Follow up*—patient should be followed with repeated physical examination and repeated VDRL is to be done at 1, 3, 6, 9, 12, 18 and 24 months. At the end of 24 months, if VDRL is negative, patient is said to be cured.
- *Prevention*—there is no dependable prophylactic measure other than sexual abstinence with infected partner. The use of prophylactic antibiotics locally is beneficial in pregnant women suspected to exposure. Prevention of congenital syphilis can be achieved by subjecting pregnant women to antenatal and postnatal check up.

Non-venereal Treponematoses

Endemic syphilis is also called as 'bejel' which is caused by spirillar form of *Treponema palladium*, yaws which is caused by *Treponema pertenue* and pinta which is caused by *Treponema carateum* are most non-venereal treponematoses which occur in children and causes destructive skin and bone diseases. These diseases run a milder course compared to venereal treponematoses.

Endemic Syphilis

It is also called as 'bejel' and most commonly occurs in childhood.

Transmission

- *Direct transfer*—direct transfer is through lesion to skin contact.
- *Indirect transfer*—indirect transfer is through the common use of drinking, bowls, or possibly by flies.

Diagnosis of syphilis

The presence of clinical manifestations together with history of a sexually active person should give clue to the diagnosis of acquired syphilis.

- *Dark field examination microscopy*—It is the most useful method of identifying spirochete in primary acquired and occasionally, secondary syphilis. Not reliable for oral lesions, since the normal flora contains non-pathogenic treponema which are difficult to distinguish from *T. pallidum*.

Clinical features

- *Age*—the disease is primarily seen in children, although adult cases are often reported.
- *Early stage*—the early stage disease is characterized by the appearance of mucus patches in the oronasopharyngeal region, angular stomatitis, skin rashes, pigmentary changes and tenderness of the long bones and regional lymphadenopathy.
- *Oral patches*—oral mucus patches are shallow, relatively painless lesions, initially seen as white which soon become erosive. The lesions are usually found on the lips, tongue and other intraoral surface.
- *Skin lesion*—skin lesions may be papular, papillomatous, macular, papulosquamous, annular or circinate.
- *Sabre tibia*—osteoperiostitis usually involving long bones is the most common manifestation which may cause nocturnal pains in the legs. Long standing osteitis and periostitis may eventually lead to forward bowing of tibia known as 'sabre tibia'.
- *Late stage*—it is seen where early endemic syphilis remains untreated for 6-9 months or even longer as an alteration in about 1/3rd of the patients or as tertiary state of the disease. Late lesions are mainly of gummatous type, involving skin, mucous membrane and bone. Skin lesions are usually extensive, chronic, destructive, scarring and with depigmentation. Gummatous destruction of nasal septum is common.
- *Rhinopharyngitis mutilans*—destruction of the lips, soft palate and nasopharynx can occur leading to gross deformity of the face.

Diagnosis

- *Clinical diagnosis*—Rhinopharyngitis mutilans with sabre tibia will give clue to the diagnosis.

Management

- *Penicillin*—it is the drug of choice and where penicillin is contraindicated; drugs such as tetracycline and erythromycin can be given.
- *Surgical correction*—surgical correction of the defects of face should be carried out for aesthetic purpose.

Pinta

It is almost exclusively confined to the Western hemisphere. The mode of transmission is either by direct or indirect contact.

Clinical features

- *Incubation period*—the incubation period is usually 2-3 weeks, after which the disease is clinically manifested. Infection is seen in young adults of 15-30 years of age.
- *Subcutaneous lesion*—the basic lesion of pinta is a solely developing subcutaneous granulomatous lesion.

- *Primary lesion*—it is believed to occur at the point of contact. They begin as small erythematous papule which enlarges within a year or two. In early lesion, pigment is lost from the germinal layer of epidermis and may become concentrated in upper layer. The primary lesion may be found on trunk, leg, face and around the anus and may be surrounded by satellite lesions.
- *Pintides*—secondary lesion of pinta is known as pintides, which appear after a period of months of years. It starts as papular lesion and develops into plaques with scaly and centrally pigmented areas. These lesions tend to become eventually depigmented. Lesions are itchy and painless. Moderate lymph node enlargement is often seen mostly due to accompanying secondary infections.
- *Late lesion*—over the period of time primary and secondary lesions become depigmented and the skin over these lesions become atrophic. Hyperkeratosis of the palms and soles accompany the formation of the achromic lesion at this stage.

Diagnosis

- *Clinical diagnosis*—skin lesion with pintides and subcutaneous granulomatous lesion will give clue to the diagnosis.

Management

- Penicillin is the drug of choice. Patients who are allergic to penicillin, tetracycline can be given.

Yaws

It is also called as 'framboesia' or 'buba'. It is caused by *Treponema pertenue*, which is pathogenic for monkeys, rabbits and hamsters. It is transmitted either by direct contact with the exudates of the early infectious lesion or indirectly by contaminated utensils.

Clinical features

- *Primary stage*—the incubation period is between 9 to 90 days. The initial lesion, a papule, appears at the site of entry of the *Treponema*. It occurs usually through an abraded or lacerated site. The lesion may ulcerate and infection can spread via bloodstream. Regional lymph nodes are usually palpable. Children with only primary lesion may complain of pain.
- *Secondary stage*—usually 1 to 3 months after the appearance of the papular primary lesion, infection spreads and a painless papilloma or frambesial granuloma appears. Lesions in the secondary stage are usually found in warm and moist sites such as axilla, groin and the skin around the natural orifices, including the mouth. They may be multiple and condylomatous in appearance. Partially, healed skin lesions often have an annular or

circinate appearance. Skin lesions may spontaneously heal in about 3 to 6 months. Bone and cartilage are involved. Lesions include osteitis, periostitis and dactylitis. In infected growing children, 'sabre tibia' develop. Plantar and palmar hyperkeratosis is also seen.

- **Tertiary stage**—tertiary lesion may occur after 5 years of primary lesion. The stage is characterized by gummatous nodular ulcerative lesion. Gummata of the skin start as subcutaneous nodules which eventually ulcerate. Osteoperiostitis, area of rarefaction and necrosis occur in long bones.

Oral manifestation

- **Lips**—during secondary stage, mucosal surface of lips may involve due to direct extension of the lesion present at the mucocutaneous junction.
- **Goundou**—secondary changes of the nasal processes of maxillary bone have been reported during the secondary and tertiary stages of the disease. These result in thickening of the face on either side of the bridge of the nose, gives rise to a characteristic facial appearance called 'goundou'.
- **Gangosa or saddle nose defect**—in some cases, the lesion starting either on the soft palate, uvula or hard palate, eventually invades and destroys soft and bony parts of nose which is called as 'Gangosa' thereby causing 'saddle nose defect'.

Diagnosis

- **Clinical diagnosis**—saddle nose defect with sabre tibia goundou shape appearance gives clue to diagnosis.

Management

- **Penicillin**—it is the drug of choice.

Gonorrhea

It is primarily an infection of the genitourinary tract mucosa. It is caused by gram -ve intrabacillary located diplococcus *Neisseria gonorrhoeae*. It is an oval, paired, gram-negative microorganism.

Local infection may occur at extra-genital site (Rectal and pharyngeal gonorrhea). Rectal mucosa is affected in 30% to 50% of women with urogenital gonorrhea. Uncomplicated local infection at other extra-genital sites is rare in adults.

Early sexual awakening, prostitution and varied sexuality are believed to be responsible for the increase incidence of gonorrhea.

Pathogenesis

- **Penetration of gonococci**—once the gonococci are directly deposited on the genitourinary tract mucosa during

sexual intercourse, they penetrate through the inter-cellular spaces of the epithelium and reach the subepithelial connective tissue.

- **Inflammatory reaction**—within 2 to 3 days of infection, an intense inflammatory reaction occurs resulting in characteristic mucopurulent discharge through urethral lumen.
- **Chronic stage**—a chronic stage may be reached, if untreated and spread is either by direct extension through lymphatics or hematogenous route.

Clinical Features

- **Age and sex**—it is primarily a disease of young adults between the ages of 15 to 24 years and is more common in males, as compared to females.
- **Location**—it is seen on genital site. Occasionally, it can involve extra-genital sites. In male, urethra is involved and in females, cervix is involved.
- **Incubation period**—incubation period is 2 to 5 days.
- **Symptoms**—there is profuse purulent urethral discharge with frequent micturition, followed by dysuria. In some of the patients, there may be fever and headache.
- **Gonococcal septicemia**—features of this include myalgia, arthralgia, polyarthrititis, dermatitis, fever, endocarditis, meningitis and oral manifestation.
- **Skin lesion**—dermatologic manifestation includes discrete papules and pustule that often contain of hemorrhagic component.
- **Gonococcal ophthalmia neonatorum**—this is the infection of infant eye which is transferred from infected mother. It may cause blindness.
- **Complication**—Cooper abscess (inflammation of periurethral glands), urethral stricture (difficulty in passing urine), arthritis, meningitis, endocarditis, epididymitis (painful swollen testicle), salpingitis or pelvic inflammatory disease (lower abdominal pain, metrorrhagia and pelvic tenderness on vaginal or rectal examination).
- **Diagnosis**—in all forms of it, including those of oral cavity and pharynx, the diagnosis rests on the identification of organism. Methods which are used include, gram stained smear, culture studies and direct fluorescent antibody test.

Oral Manifestations

- **Pharyngeal gonorrhea**—Pharyngeal gonorrhea is a term used for patients in whom *neisseria gonorrhoea* is isolated from nasopharynx. It is higher in pregnant women, sexually active homosexuals and heterosexuals practicing oral sex. History of fellatio is more associated with pharyngeal gonorrhea. Patient also noticed sore throat and evidence of pharyngitis.

- *Gonococcal stomatitis*—incidence is very rare and often shows multiple, painful and round elevated gray white eroded spots, with or without pseudomembrane formation. Regional lymphadenopathy may be seen. The wide range of lesion may develop in gonococcal stomatitis i.e. isolated ulcers, gingivitis and membranous gingivostomatitis.
- *Gingivitis*—acute gingivitis develops around extraction site in patient who practices fellatio repeatedly for days after extensive dental extraction. Gingiva may become erythematous, with or without necrosis.
- *Lips*—lips may develop acute painful ulcerations, limiting the motion.
- *Tongue*—the tongue may present red, dry ulcerations or become glazed and swollen with painful erosion with similar lesions on buccal mucosa and palate.
- *Temporomandibular joint involvement*—gonococcus infection involving articulating joint is the most common form of extragenital gonorrhea. Any joint may be affected, the commonest being knee, ankle and wrist. TMJ is affected in 14% of patients. It occurs as a result of hematogenous spread. Patient noticed difficulty in jaw movements due to pain and swelling of single or both joints is the presenting symptom. Rarely, perforation to the tympanic plate occurs. It may lead to fibrous ankylosis because articular cartilage is destroyed.
- *Types of gonococcal arthritis*—Wright has divided Gonococcal arthritis in two different categories:
 - *Category I*—Definite gonococcal arthritis—gonococci recovered in an aspirate from the affected joint.
 - *Category II*—Probable gonococcal arthritis. No gonococci recovered from the joint, but each of the following conditions exist.
 - Presence of gonococcal urethritis proven on smear or culture.
 - Arthritis occurring within 3 weeks of probable gonococcal infection.
 - Articular manifestations responding rapidly to antigenococcal therapy.

Radiographic Features

Radiologically, the joint reveals no abnormalities. Rarely, perforation through the tympanic plate may occur.

Diagnosis

- *Clinical diagnosis*—purulent urethral discharge with pharyngitis with TMJ involvement can give clue to diagnosis.

Differential Diagnosis

- *Primary syphilitic lesion*—painless indurated edema, painless lymph node swelling, causative agent in lesion.

- *Tuberculosis ulcer*—undermined, flabby border—usually painless, tuberculin test positive.

Management

- *Antibiotics*—single dose of the broad-spectrum cephalosporin antibiotic ceftriaxone 125 to 250 IM plus doxycycline 100 mg orally, twice a day for 7 days. In case of patient allergic to above drug, sepectinomycin 2 gm IM plus doxycycline. In some cases, orally or intramuscular administered fluorinated Quinolones may be helpful.
- *Prophylactic treatment*—prophylactic ophthalmic erythromycin should be given to prevent gonococcal ophthalmia neonatorum.
 - Recurrence—without adequate treatment, disease will recur.

Streptococcal Tonsillitis and Pharyngitis

The most common cause of this condition is beta hemolytic streptococci, adenoviruses, enteroviruses, influenza and parainfluenza.

Clinical Features

- *Symptoms*—sudden onset of sore throat, fever, dysphagia.
- *Signs*—redness of oropharynx and tonsils (**Fig. 30-2**), palatal petechiae and yellowish tonsillar exudate.
- *Lymph nodes*—there is cervical lymphadenopathy.
- *Systemic features*—headache, anorexia, abdominal pain and vomiting can also occur.

Fig. 30-2: Inflammation of pharynx and tonsil seen in streptococcal pharyngitis and tonsillitis.

Diagnosis

- *Clinical diagnosis*—tonsillitis with cervical lymphadenopathy will lead to diagnosis.

Management

- *Antibiotics*—penicillin and cephalosporin should be given. Erythromycin should be used in patient who is sensitive to penicillin.
- *Analgesic*—analgesic should be given to control pain and inflammation.
- *Warm saline gargle*—it is also effective treatment in case of tonsillitis.

Leprosy (Hansen Disease)

It is a chronic infectious disease which has predilection for the skin, nerves and mucous membrane. It probably originated in tropic and spread to the east. Leprosy has always been considered in superstitious dread and the person suffering from leprosy was considered unclean and socially outcasted.

It is caused by the leprae bacillus, *Mycobacterium leprae*, first observed by Hansen in 1868. It is not been possible to grow the bacillus in culture media. It is an acid fast, gram positive, non-motile bacteria with affinity for Schwann cells and cells of reticuloendothelial system.

Pathogenesis

- *Multiplication of bacteria*—after entry in the body the bacilli reach the lymphatic and bloodstream and are taken up by Schwann cells in peripheral nervous system, where they start multiplying. If the host cell mediated immunity is adequate, bacilli are destroyed and there is no disease. In the host, immunity is unstable and suboptimal, there will be some restricted multiplication of bacilli and lesion will develop.
- *Effect of immunity*—the variable status of host cell mediated immunity is reflected in the different clinical types of leprosy. When there is relatively good immunity but not enough to eliminate the infection, a localized type of disease called as tuberculoid type, is seen. When the host cell immunity is deficient a generalized form of the disease lepromatous leprosy develops.
- *Borderline variety*—in between these two polar varieties of the disease, there is a wide spectrum of manifestations, categorized as borderline leprosy.

Types

- *Tuberculoid leprosy*—it develops in patient with high immune reaction. It is localized. It is a benign form of leprosy involving the skin, nerves and regional lymph node.

- *Lepromatous leprosy*—this is present in reduce cell mediated immune response.
- *Borderline leprosy*—it can be tuberculoid borderline or lepromatous borderline.
- *Polyneuritic*—in this, multiple nerves are involved by the bacteria.
- *Indeterminate*—no specific lesion is found in this type of leprosy.
- *Erythema nodosum leprosum*—this is the severe form of leprosy.
- *Paucibacillary leprosy*—it corresponds to tuberculoid type of leprosy and lesions are limited to skin.
- *Multibacillary leprosy*—this corresponds to lepromatous type and involves multiple organs.

Clinical Manifestations

Tuberculoid type or paucibacillary type

- *Incubation period*—incubation period of 2 to 5 years during which patient passes through silent or latent period.
- *Sex*—males are affected more commonly than females with ratio of 3:1.
- *Skin*—lesions are hypopigmented, erythematous and flat or raised cutaneous lesions. Nerve involvement with loss of different types of sensation is also manifested.
- *Early tuberculoid leprosy*—it is manifested by hypopigmented macules which are sharply demarcated and hyperesthetic.
- *Intermediate tuberculoid lesion*—later, the lesions are larger with elevated and circinate margin. There is peripheral spread (Fig. 30-3) and central healing. At the end of this stage, the symptoms are those of irritation of nerve ending in the skin, persistent or recurrent paresthesia and numbness localized to certain area with no accompanying visible alteration in the corresponding skin lesion.

Fig. 30-3: Lesion of tuberculoid leprosy showing peripheral spread (Courtesy Dr Pincha).

- **Fully develop lesion**—in this, lesions are densely anesthetic and loose normal skin organs (sweat glands and hair follicles). There may be severe neuritic pain. Loss of eyebrows and eyelashes are prominent features of later involvement.
- **Peripheral nerve**—the sequelae of peripheral nerve involvement may develop in some cases and this may give rise to muscle atrophy, like contracture of hands and feet, loss of phalanges, lagophthalmus, exposure keratitis and corneal ulceration leading to blindness.

Lepromatous type or multibacillary leprosy

- **Age and sex**—this form is more commonly seen in children and females are affected more as compared to males.
- **Site**—this malignant form of the disease produced widespread involvement of body skin, peripheral nerves, mucous membrane, lymph nodes, eyes, skeleton, testes and other internal organs. It runs chronic course and seldom causes sudden death.
- **Appearance**—it develops early as erythematous macules (Fig. 30-4) or papules without subsequently lead to progressive thickening of skin and the characteristic nodules.
- **Margins**—the borders of the lesion are ill defined and centers of the lesion are indurated and convex.
- **Eyes**—loss of lateral portion of eyebrows is common.
- **Lymph nodes**—painless inguinal and axillary lymphadenopathy is common along with sterility and gynecomastia.
- **Nerve involvement**—nerve involvement is a late phenomenon.

Fig. 30-4: Macular lesion seen on the leg of patient in lepromatous leprosy.

- **Claw hand**—this is one of the typical features of leprosy (Fig. 30-5).

Fig. 30-5: Claw hand seen in lepromatous leprosy.

Erythema nodosum leprosum (ENL)

- **Occurrence**—they occur in lepromatous and borderline lepromatous patients, most frequently in the latter half of the initial year of treatment.
- **Signs**—tender, inflamed subcutaneous nodules develop, usually in crops. Each nodule lasts a week or two, but new crop may appear.
- **Symptoms**—low grade fever, lymphadenopathy and arthralgia can accompany severe ENL.
- **Leporma**—this is common feature of erythema nodosum leprosum (Fig. 30-6).

Facial manifestations

- **Prevalence**—depending on the type and duration of the disease, all patients with lepromatous leprosy show facial and oral manifestations and it is rare in tuberculoid and borderline leprosy.
- **Leonine facies**—the skin of face and forehead become thickened and corrugated giving a patient distorted facial appearance (leonine facies) (Fig. 30-7).

Fig. 30-6: Leproma in erythema nodosum leprosum presented as inflammatory swelling.

Fig. 30-7: Facial appearance in leprosy (note the saddle nose).

- *Ear*—earlobe becomes pedunculous due to lepromatous infiltration of the helical and lobes of ear.
- *Symptoms*—there is nasal stiffness, epistaxis, hoarseness.
- *Appearance*—the lesions are macular or raised, well defined, hypopigmented, unhydropic and hyperaesthetic or anesthetic.
- *Advanced cases*—advanced cases are characterized by nodular involvement of facial, cutaneous and subcutaneous structure.
- *Neural changes*—peripheral nerves such as facial and trigeminal nerves are frequently involved. Facial paralysis is observed in 3% of cases, complete or partial facial paralysis may occur either unilaterally or bilaterally. Paralysis of the orbicularis muscle results in facial disfigurement, difficulties in phonation and mastication as well as drooling. Involvement of trigeminal nerve results in hypoaesthesia and anesthesia.
- *Facies leprosa*—rhinomaxillary changes termed facies leprosa consist of atrophy of anterior nasal spine, atrophy and recession of the maxillary alveolar process confined to the incisor region and endonasal inflammation.
- *Saddle nose*—from nasal mucosa, granulomatous tissue invade cartilage and bone resulting in nasal collapse. The appearance is called as saddle nose (Fig. 30-7).
- *Chronic osteomyelitis*—destruction of facial cartilage and bone is caused by direct infiltration and secondary infection which results in chronic osteomyelitis.

Oral manifestation

- *Prevalence*—it is more commonly seen in lepromatous
- *Site*—involvement of oral mucosa, pre-maxilla, soft palate, uvula, tongue, gingiva and periodontium has been reported.

- *Lepromas*—small tumor like masses called as lepromas develop on the tongue, lips or hard palate. These nodules have a tendency to break down and ulcerate. Continuous infection may lead to scarring and loss of tissue.
- *Gingiva*—gingival hyperplasia with loosening of teeth have been also reported.
- *Tooth size and shape*—in association with severe and granulomatous infiltration of pre-maxilla in childhood, the tooth diameter is suddenly and concentrically reduced, while the less marked cases exhibit a well demarcated, tapering and shortening of root.
- *Enamel hypoplasia*—transient interruption of odontogenesis results in slight, circumferential hypoplasia of enamel and cementum.
- *Pulpal necrosis*—in long standing lepromatous leprosy, invasion of the pulp by granulomatous tissue causes pulpal necrosis leading to a pinkish discoloration of crown. Anterior teeth are most commonly affected.

Diagnosis

- *Ziehl-Neelsen stain*—skin smears should be examined as a routine with Ziehl-Neelsen stain. The percentage of solid bacilli in a smear is known as morphological index.
- *Biopsy*—skin, mucosal and nerve biopsy for histopathological examination are helpful in doubtful cases.
- *Lepromin test*—lepromin test is non-specific test to determine the hypersensitivity reaction and is useful in determining the immunological status of patient for classification of leprosy.

Differential Diagnosis

- *Gummatous lesion of syphilis*—VDRL test should be performed.
- *Ulcerative proliferative lesion of coccidioidomycosis and sporotrichosis*—peripheral nerve involvement is common in leprosy.

Management

- *Paucibacillary leprosy*—it is treated with 6 month regimen of rifampin and dapsone. Patient allergic to rifampin are treated with clofazimine, ofloxacin and minocycline.
- *Multibacillary leprosy*—this is treated with 24 months therapy of rifampin, dapsone and clofazimine.
- *Reconstructive surgery*—reconstructive and plastic surgery is essential for deformities of the hand and face
- *Vaccine*—BCG vaccines provide some protection against non-lepromatous leprosy.
- *Social development*—environmental changes with social and economic development are useful.

Tuberculosis

It is a systemic infectious disease of worldwide prevalence and of varying clinical manifestations. It is an infectious granulomatous disease caused by acid-fast bacilli *Mycobacterium tuberculosis* or rarely, *Mycobacterium bovis*. It can rarely be transmitted through the placenta from the diseased mother to fetus.

Pathogenesis

- **Primary infection**—initial tuberculosis usually occurs in lungs but occasionally, occurs in tonsil or alimentary tract. The common cause of primary infection is inhalation. In most of the patients of primary infection, the associated lymph node lesions heal and calcify.
- **Rupture of caseous tuberculosis foci**—in some cases, caseous tuberculosis focus ruptures into vein and produces acute dissemination throughout the body, a condition called as acute miliary tuberculosis. Meningitis often complicates this condition.
- **Progressive pulmonary tuberculosis**—progressive pulmonary tuberculosis may develop directly from a primary lesion or may occur following reaction of an incompletely healed primary focus.
- **Post-primary pulmonary tuberculosis**—post-primary pulmonary tuberculosis is a condition in which, there is a liquefied center of tuberculosis, pulmonary infection is discharged into sinus. Extension of infection into pleura causes tuberculosis pleurisy.

Etiology

- **Causative organism**—the first member identified as tuberculous bacillus and designate as *Mycobacterium tuberculosis*. Other microorganisms associated are *Mycobacterium bovis*, *Mycobacterium kanasasi*, *Mycobacterium xenopi* and *Mycobacterium malmoeense*. The organism is anaerobic, non-motile, non-sporing, rod shaped and is stained with special Ziehl-Neelsen stain.
- **Constitutional factor**—it is more common in low income group, unhygienic living conditions, malnutrition and overcrowding.

Predisposing Factors for Oral Infection

- **Systemic factors**—systemic factors like lowered host resistance and increased virulence of the organism may lead to oral manifestation in the tuberculosis patient.
- **Local factors**—local factors like poor oral hygiene, local trauma, presence of pre-existing lesion such as leukoplakia, periapical granuloma, dental cyst, dental abscess, jaw fracture and periodontitis are also responsible for oral infection.

Types

- **Primary tuberculosis**—it occurs in previously unexposed person and it involve lung.
- **Secondary tuberculosis**—in this reactivation of bacteria and it occur in, compromised host defense.
- **Miliary tuberculosis**—it spreads through bloodstream and there is wide involvement of many organs like kidney, liver and is called as miliary tuberculosis.
- **Pott's disease**—if tubercular involvement of spine occurs in children, it is called as Pott's disease.
- **Scrofula**—if it spreads by lymphatics to lymph nodes, it is called as scrofula.

Clinical Features

- **Age**—they are relatively uncommon and seen in middle and older age groups, as cleansing action of saliva and its antibacterial properties, in general also provide protection against tubercle bacilli.
- **Symptoms**—patient may suffer episodes of fever and chills, easy fatigability and malaise. There may be gradual loss of weight accompanied by persistent cough with or without hemoptysis. Local symptoms depend upon the tissue or organs involved.
- **Signs**—tubercular lymphadenitis may progress to acute abscess or remain as granulomatous lesion (**Fig. 30-8**). In any case, swelling of neck is present which is tender, painful and often show inflammation of the overlying skin. When abscess forms, it perforates and discharges pus.

Fig. 30-8: Tubercular lymphadenitis showing swelling in the submandibular region (Courtesy Dr Chole).

- *Pulmonary tuberculosis*—a persistence cough, hemoptysis, abundant sputum are usual features of pulmonary tuberculosis. There is also evening rise in temperature of 0.5° to 2°F. Night sweats is also present.
- *Scrofula*—in glandular form of the disease, there is marked enlargement of the cervical lymph nodes with caseation and frequent breakdown of the gland. Such tuberculous infection is called as 'scrofula'. It is usually caused by ingestion of unpasteurized infected cow milk.
- *Cold abscess*—the chronicity of the infection and the lack of marked pain or acute inflammatory symptoms have resulted in the term 'cold abscess'.
- *Consumption*—progressive tuberculosis may lead to wasting syndrome called as *consumption* as it appear as patient body is consumed or destroyed.
- *Lupus vulgaris*—involvement of skin in tuberculosis is term as lupus vulgaris.

Oral Manifestations

- *Site*—tongue is most commonly affected followed by palate, lips, buccal mucosa and gingiva.
- *Primary oral lesion*—it develops when bacteria is directly inoculated in the oral tissue of a person who has not acquired immunity to the disease. It involves gingiva, tooth extraction socket and buccal fold.
- *Secondary oral lesion*—infection is carried by hematogenous route or through break in the tissue surface, is deposited in the submucosa, subsequently proliferates and ulcerates the overlying mucosa. It occurs more frequently in cases of extra-pulmonary tuberculosis.
- *Tubercular ulcer*—the lesion may be preceded by an opalescent vesicle or nodule, a result of caseation necrosis. It breaks down into an ulcer which is usually superficial or deep and painful. Margin of the ulcer are undermined with minimum induration. It tends to be increased slowly in size. Mucosa surrounding the ulcer is inflamed and edematous. Base of ulcer is yellowish and granular.
- *Sentinel tubercle*—tiny, single and multiple nodules called 'sentinel tubercle' may also be seen surrounding the ulcer.
- *Mucocutaneous junction*—at the mucocutaneous junction, tubercular ulcers are usually extremely shallow with granulating base. Crusting and oozing is seen when the lesion involves adjacent cutaneous surface. They are usually painful.
- *Nodular form*—the nodular form of tuberculosis presents as single or multiple nodules of variable sizes, which initially may appear as semitransparent lesion of pinhead size. They are gray in size and of variable consistency.
- *Miliary tubercle*—miliary tubercle of oral mucosa are occasionally seen in miliary tuberculosis which is a result of acute dissemination of the infection through hematogenous and lymphatic channel. The oral lesion appears as small, gray tubercle with the tendency to break down and ulcerate.
- *Periapical tissue*—tubercle involvement of the periapical tissue and tooth socket have been reported. The socket may be filled with so called tuberculosis granulation tissue, consisting of many small, pink and red elevations.
- *Tuberculosis gingivitis*—tuberculosis gingivitis is an unusual form which may appear as diffuse, hyperemic or nodular papillary proliferation.
- *Jaw involvement*—it may involve maxilla or mandible. Jaw bone involvement occur as a result of either deep extension of a gingival lesion, from infected extraction socket, an extension of tubercular granuloma at the apex of tooth or by means of hematological spread. It may result in more diffuse form of osteomyelitis and is normally more serous than infections from periapical lesion.
- *Symptoms of jaw involvement*—tubercular involvement of jaw bone causes swelling and the symptoms include difficulty in eating, trismus, paresthesia of the lower lip and enlargement of the regional lymph nodes. Fistulae drain either intraorally or extraorally often with blue margins.
- *Temporomandibular joint*—in some cases, destructive involvement may reach to the TMJ area.

Radiographic Features

General

- *Early changes*—the chest radiograph in patient with secondary tuberculosis may show fibronodular changes most often in upper lobe. There is also cavity formation and volume loss. The earliest changes usually are ill defined opacity or opacities situated in the upper lobes.
- *Advanced cases*—in more advanced cases, opacities are larger and more widespread and may be bilateral. An area of translucency within the opacities indicates cavitations.
- *Displacement of trachea*—trachea and mediastinal structures are displaced towards the side of the lesion.

Oral

- It may be described as a localized or diffused with wide variation in size.
- *Location*—mandibles show greater predisposition than maxilla.
- *Localized lesion*—the localized lesion is of rarefying osteitis, while diffuse one is the nature of osteomyelitis.
- *Diffuse lesion*—in diffuse type of tuberculosis of bone, scattered area of bone destruction separated by portions of bone having normal or near normal appearance are seen.

- *Periostitis*—in some cases, tuberculosis may result in laying down the bone which resembles periostitis.

Diagnosis

- *Microscopy*—a pulmonary TB suspect, should submit 3 sputum samples for microscopy. Morning sample is ideal.
- *Staining method*—Ziehl-Neelsen, carbol fuschin or kinjoun carbol fuschin have been used for staining mycobacterium.
- *Polymerase chain reaction*—this technique amplifies even very small proteins of predetermined target region of *Mycobacterium tuberculosis* complex DNA.
- *Tuberculin skin test*—the Mantoux test is the preferred skin test for detecting tuberculosis. It involves the injection of 5 Tuberculin unit of purified protein derivatives, usually 0.1 ml intradermal. The skin test is read on the basis of millimeters of induration produced by PPD. 10-15 mm induration is required for the test to be positive.

Dental Considerations

- *Evaluation of patient*—Dental personnels are at constant risk of contacting the disease while treating the patient of tuberculosis. It is known that smallest droplet of contaminated saliva from the patient may be sufficient source of contagion, particularly if they are inhaled by previously uninfected or non-immunized individual. Patient with past history of tuberculosis should be evaluated by the physician to ensure the course of the treatment and follow up.
- *Delayed dental treatment*—if the culture is positive, dental treatment should not be performed unless there is emergency. In emergency dental treatment special precautions should be taken.
- *Protection of doctors*—to avoid aerosolization use of rubber dam and minimum use of ultrasonic scalers and high speed handpieces should be done. The operating air should be vented to the outside, i.e. not recirculated.

Differential Diagnosis

- *Syphilis*—primary lesion is harder and spirochetes are found.
- *Traumatic ulcer*—short duration and history of trauma.
- *Sarcoidosis*—tuberculin test negative, the granuloma of sarcoidosis are of non-necrotizing type.
- *Lupus erythematosus*—histology, causative agent test negative, skin changes.
- *Leukemia*—immature WBCs, prolonged bleeding and clotting time.

Management

- *Chemotherapy*—short term chemotherapy, isoniazid (5 mg/kg with maximum of 300 mg daily or 15 mg/kg two to three times weekly) and rifampicin (10 gm/kg), ethambutol (25 gm/kg daily for not more than 2 months).
- *Other drugs*—other drugs which can be used are streptomycin, para-aminosalicylic acid, pyrazinamide, thiacetazone, ethionamide and cycloserine.
- *Surgery*—surgery is rarely performed nowadays, as most patients respond well to medication. When indicated, it is usually for a persisting pulmonary cavity with acid-fast positive sputum despite 6 months of chemotherapy. The usual type of surgery done is segmental resection of lung or a complete lobectomy.

Actinomycosis

It is a chronic granulomatous suppurative and fibrous type of disease caused by anaerobic, gram +ve, non-acid fast bacteria. Most common are *Actinomyces israelii*, *A. nasalandi*, *A. viscosus* and *A. odontolyticus*. The organism is considered to be transitional form between bacteria and fungi. The term Actinomyces was given by Harz to refer the 'ray-like appearance' of the organism in the granule.

Classification

- *Cervicofacial*—it involve facial and cervical region.
- *Abdominal*—it is serious form and involves abdomen.
- *Pulmonary*—in this, there is pleural invasion resulting in empyema.
- *Cutaneous*—there is subcutaneous swelling in this form.
- *Central*—here, the infection is from the tooth or its membrane and is accompanied by radiographic changes.
- *Peripheral*—the peripheral types originate in the soft tissues and do not involve bone.

Predisposing Factors

- *Trauma*—the breach in the continuity of mucosa caused either by trauma or surgery, if the prerequisite for majority of actinomycosis infections.
- *Local factors*—cervicofacial actinomycosis infections are endogenous in origin and occur when dental plaque, calculus or gingival debris contaminate the relatively deep wounds around the mouth. Presence of carious teeth may act as predisposing factors for actinomycosis.
- *Others*—secondary bacterial invasion and hypersensitivity reaction may act as predisposing factors for actinomycosis.

Clinical Features

Cervicofacial form

- **Age**—it is most common type of actinomycosis and is commonly seen in adult males.
- **Location**—submandibular region is the most frequent site of infection. It usually spreads by direct tissue extension. Cheek and masseter region and parotid gland may also be involved.
- **Symptoms**—trismus is a common feature, before the formation of pus.
- **Signs**—the first sign of infection is characterized by the presence of a palpable mass. Mass is painless and indurated.
- **Sinus and fistula**—development of fistula and sinus is common. Skin surrounding the fistula is purplish (**Fig. 30-9**). Adjacent tissues have doughy consistency.
- **Sulfur granules**—several hard circumscribed tumors like swelling may develop and undergo breakdown, discharging a yellow fluid containing the characteristic submicroscopic sulfur granules.
- **Ray fungus appearance**—round or lobulated colony mesh-work of filaments stain with hematoxylin and peripheral club shaped ends of filaments stain with eosin.

Fig. 30-9: Fistula seen in patient of actinomycosis (Courtesy Dr Patle).

Abdominal form

- Abdominal actinomycosis is extremely serious form of the disease.
- **Precipitating factors**—trauma, due to surgery or other causes such as fish bone or chicken bone injury, usually precedes the onset of the disease.
- **Symptoms**—generalized symptoms of fever, chills, vomiting, develop followed by symptoms of involvement of organs, such as liver and spleen.
- **Sign**—there is palpable abdominal mass. Intestinal manifestations develop later.

Pulmonary form

- **Symptoms**—it produces findings such as fever and chills, accompanied by a productive cough and pleural pain.

- **Signs**—pleural invasion resulting in empyema and there may be formation of sinus.

Subcutaneous form

- **Cause**—infection result from traumatic transplantation of organism, usually due to human bites.
- **Signs and symptoms**—lesion seen as subcutaneous swelling which enlarges slowly softens and ruptures through the sinuses. Occasionally, these lesions burrow through deeper tissue and invade bones.

Oral Manifestations

- **Cause**—organism may enter the tissue through oral mucous membrane and may either remain localized in the adjacent soft tissue or spread to involve salivary glands, bone or skin of face and neck.
- **Signs**—it produces swelling and induration of tissue. It may develop into one or more abscesses, which tend to discharge upon the skin surface liberating pus, which contains typical sulfur granules. There may be non-healing tooth socket, exuberant granulation tissue and periosteal thickening of alveolus. Skin overlying abscess is purple red and indurate or fluctuant.
- **Sinus**—it is common for sinus, through which the abscess has drained, to heal but due to chronicity, new abscesses are formed and perforate through skin surface.
- **Face**—there is disfigurement of face. Infection may involve maxilla and mandible.
- **Periapical granuloma**—there is formation of periapical granuloma.
- **Tongue**—on the tongue, the lesion is a painful nodule which eventually ulcerates. Untreated cases may reach to the point where the tongue may become fixed.
- **Actinomycosis osteomyelitis**—it can occur in patient with periodontal infection, nonvital teeth.

Radiographic Features

- **Appearance**—it may appear as an area of bone destruction, which resembles a dental cyst, with a well defined area of radiolucency with cortical lining of dense bone.
- **Lamina dura**—lamina dura is deficient at the apex of tooth.
- **Rarefying osteitis**—scattered area of bone destruction, separated from one another by normal or sclerosed bone, is another manifestation.
- **Tooth features**—the persistence radiolucency of tooth socket with an increased density of adjacent bone may be the first sign of disease.

Diagnosis

- **Clinical dagnosis**—sulphur granules with development of fistula and sinus with fever give clue to diagnosis.

- *Radiological diagnosis*—loss of lumina dura with scattered area of bone destruction.
- *Laboratory diagnosis*—typical key fungus appearance is seen.

Management

- *Two fold therapy*—actinomyces infection produces a reactive inflammatory response which causes an area of necrosis and scar tissue around the abscess. This results in decrease in the vascular supply to the affected region and hence, makes penetration of antibiotics difficult. Therefore, two fold therapy including antibiotics and surgery is necessary.
- *Surgical*—the lesion should be surgically removed and the surrounding area should be thoroughly debride.
- *Antibiotics*—following surgical intervention, antibiotics therapy should be continued. The antibiotic of choice is penicillin which should be given 3 to 4 million IV, every 4 hours for 2 to 4 weeks. This should be followed by 0.5 to 12 gm of penicillin, four times a day for 4 to 6 weeks. In patients allergic to penicillin, tetracycline orally 500 mg given four times a day for 6 months.
- *Other drugs*—other agents used in the treatment of actinomycosis include cephalosporin, clindamycin and lincomycin.

Noma

It is also called as 'Cancrum oris', 'gangrenous stomatitis', 'necrotizing stomatitis'. Noma is derived from the word *nomein* meaning to devour (eat greedily). It is rapidly spreading gangrene of oral and facial tissues occurring usually in debilitated or nutritionally deficient person. It is caused by *Fusobacterium necrophorum*.

Predisposing Factors

- *Poverty*—it occur in persons who are undernourished.
- *Debilitated disease*—debilitated infections such as diphtheria, dysentery, measles, pneumonia, scarlet fever, syphilis, measles, tuberculosis and blood dyscrasias.
- *Injury*—excessive mechanical injury is also predisposing factors.
- *Poor oral hygiene*—this may lead to growth of the bacteria causing increased susceptibility for the infection.
- *AIDS*—as it is immunological disorders, it can lead to Noma.
- *Others*—miscellaneous factors such as leukemia, sickle cell trait, stress and chemotherapeutic agents can cause noma.

Clinical Features

- *Age*—it is seen chiefly in children, but can be found in adults in certain conditions like in malnourished states.

- *Sites*—common sites are areas of stagnation around fixed bridge or crown.
- *Onset*—the commencement of gangrene is denoted by blackening of skin.
- *Necrotizing ulcerative mucositis*—small ulcers of gingival mucosa spread rapidly and involves the surrounding tissues of jaws, lips and cheeks by gangrenous necrosis.
- *Symptoms*—lesion has foul odor. Patients have high temperature during the course of the disease, suffer secondary infection and may die from toxemia or pneumonia.
- *Skin*—overlying skin is inflamed, edematous and finely necrotic which results in formation of line of demarcation between healthy and dead tissue.
- *Advanced stage*—in advanced stage, there is blue-black discoloration of the skin. As gangrenous process advances, slough appears and soon separated, leaving a perforating wound in the involved area (**Fig. 30-10**).
- *Noma neonatorum*—it arise in first month of low birth weight infants who are having malnutrition. Infants have lesion on lips, nose, mouth and anal area.
- *Jaw*—large masses may be sloughed out leaving the jaws exposed.
- *Complication*—it includes pneumonia, diarrhea, and septicemia. This can lead to death of patient.

Diagnosis

- *Clinical diagnosis*—blue black discoloration of skin with sloughing of tissue will give clue to diagnosis.

Fig. 30-10: Blackish discoloration with ulceration seen in case of gangrenous stomatitis (Courtesy Dr Tapasya).

Management

- *Control of dehydration and electrolyte balance*—parenteral fluid should be given urgently to correct dehydration and electrolyte balance.
- *Blood transfusion*—blood transfusion helps in improving the clinical state of the patient, who is usually anemic and toxic.
- *Antibiotics*—the specific drug of choice is penicillin although sulphonamides also yield good results. Other antibiotics which are used are gentamicin, clindamycin.
- *Reconstructive surgery*—reconstructive surgery is necessary to lead near normal life.

Scarlet Fever

Predominately occurs in children during winter months, caused by infection with group-A streptococci of beta hemolytic type that elaborate erythrogenic toxins.

Clinical Features

- *Incubation period*—incubation period is 1 to 7 days.
- *Symptoms*—patient exhibits severe pharyngitis and tonsillitis, chills, fever and vomiting.
- *Signs*—throat becomes highly erythematous and exudation is common. There may be enlargement and tenderness of regional lymph nodes.
- *Skin rash*—characteristic diffuse, bright scarlet to dusky red skin rash which appear on the second or third day of the illness (**Fig. 30-11**). This rash is also called as 'sunburn with goose pimples'. Rash is more intense in areas of pressure and skin fold. There is a transverse red streak which is called as 'Pastia's line'. After 3 to 4 days, the rash fades. This rash is due to toxic injury to the vascular endothelium which produces dilation of the small blood vessels and consequent hyperemia.

Fig. 30-11: Rash of scarlet fever seen on the skin of the hand (Courtesy Dr Pincha).

Oral Manifestations

- *Stomatitis scarlatina* accounts for the chief oral manifestation of scarlet fever.
- *Palate*—mucosa of palate may appear congested. Ulceration may also occur on palate.
- *Face*—the face, especially the temporal region and cheeks are flushed and red, but pale area of circumoral pallor is often seen around the mouth.
- *White strawberry tongue*—tongue exhibits white coating and fungiform papillae are edematous and hyperemic, projecting above the surface as small red knobs and it is called as 'strawberry tongue'.
- *Red raspberry tongue*—coating of tongue is soon lost, beginning at the tip and lateral margins and the organ becomes deep red, glistening and smooth, except for swollen hyperemic papilla. The tongue in this phase is called as 'raspberry tongue'.
- *Teeth*—in some cases, hypoplasia of teeth is seen in permanent teeth, if conditions occur at the time of tooth development.

Complications

- *Hypersensitivity reaction*—localized or generalized bacterial dissemination or hypersensitivity reaction to the bacterial toxins.
- *Systemic complication*—peritonsillar abscess, rhinitis, sinusitis, otitis media, mastoiditis, meningitis, pneumonia, glomerulonephritis, rheumatic fever and arthritis.
- *Oral complication*—it includes cancrum oris, ulceration with perforation of palate, osteomyelitis and involvement of the temporomandibular joint.

Diagnosis

- *Clinical diagnosis*—white strawberry and red raspberry tongue are typical of scarlet fever.

Differential Diagnosis

- *Pernicious anemia*—tongue in pernicious anemia is not as red as in scarlet fever.
- *Atrophic glossitis in vitamin deficiency*—swab culture of oropharynx disclose the presence of hemolytic streptococci and antistreptolysin -O titer is elevated.

Management

- *Antibiotics*—penicillin is the drug of choice, since group A streptococci are generally highly sensitive to this antibiotic. The species are also sensitive to other antibiotics like erythromycin, tetracycline and chloramphenicol.

Diphtheria

It is an acute contagious disease caused by gram +ve bacillus *Corynebacterium diphtheriae*, also called as *Klebs*

Loeffler bacillus. It is transmitted by droplet infection or direct contact.

Pathogenesis

- *Portal of entry*—the portal of entry is the upper respiratory tract and rarely skin, genitalia, eye and middle ear.
- *Incubation of bacteria*—the bacilli settle on the mucous membrane or upper respiratory tract and lead to inflammation and necrosis of mucosal cells. The infection may spread to adjacent areas.
- *Primary area*—in the primary invasive region, it forms a thick, firm, leathery, blue white pseudomembrane composed of bacteria, necrotic epithelium, macrophages and fibrin. A narrow zone of inflammation surrounding the area is seen.
- *Secondary area*—when the diphtheria bacteria multiply in the local tissues, they produce powerful exotoxins. This exotoxin diffuses through the body through a hematogenous route. Heart, muscle, kidney, peripheral nerves and adrenal glands are thus involved. Death may be caused by heart failure, airway obstruction which is caused by edema or by the effect of toxin.

Clinical Features

- *Age*—it occurs most frequently in children, during the fall and winter months.
- *Incubation periods*—incubation period is two days.
- *Symptoms*—listlessness, malaise, headache, fever and occasional vomiting. Within a short time, patient complains of sore throat.
- *Signs*—mild redness and edema of pharynx with cervical lymphadenopathy.
- *Bull neck*—there may be swelling of the neck, called as 'bull neck'.
- *Nose*—soft palatal paralysis can lead to nasal regurgitation of liquids during drinking.
- *Larynx*—larynx is edematous and is covered by pseudo-membrane. It produces a mechanical respiratory obstruction and typical croup.
- *Neural involvement*—there is generalized polyneuritis with weakness; paresthesia may follow in the next 10 to 14 days.
- *Complication*—it includes myocarditis, polyneuritis and acute intestinal nephritis.

Oral Manifestations

- *Diphtheritic membrane*—formation of patchy 'diphtheritic membrane' which begins on tonsils and enlarges, becoming confluent over the surface. It is thick and grayish in color.

- *Signs*—it tends to adhere and leave a raw bleeding surface on removal.
- *Soft palate*—soft palate temporary paralysis usually during 3rd and 5th week of the disease. The paralysis usually disappears in a few weeks or few months.

Diagnosis

- *Clinical diagnosis*—bull neck, sore throat with edematous larynx will give clue to diagnosis.

Prevention

- The disease may be prevented by prophylactic active immunization with diphtheria toxoid.

Differential Diagnosis

- *Herpes simplex infection*—small blisters, small shallow ulceration and history of prodromal symptoms. No patch on soft palate.
- *Hand-foot-mouth disease*—nausea, diarrhea, fever and vesiculoulcerative lesion occur simultaneously in the oral cavity and on hand and feet. No patch is seen.

Management

- *Rest*—the patient should be isolated and bed rest is very essential.
- *Antitoxin*—it is treated with diphtheria antitoxin. Mild cases treated with 10,000 to 20,000 units of antitoxin. Moderate cases with 20,000 to 40,000 units and severe cases with 50,000 to 100,000 units of antitoxin.
- *Antibiotics*—along with antitoxin antibiotics like penicillin and erythromycin should be given.

Cat Scratch Disease

It is also called as 'cat scratch fever'. This is most common cause of chronic regional lymphadenopathy. The etiological agent is unknown. Viral as well as bacterial agents have been proposed as the cause of this disease. Initially, causative organism is named as *Rochalimaea henselae* but later on, it is named as *Bartonella henselae*.

Clinical Features

- *Age*—it occur at any age, but predominant in children and young adults. It is thought to arise after traumatic break in skin due to scratch or bite of household cat.
- *Incubation period*—the incubation time of the disease ranges from 3-14 days.
- *Symptoms*—in early stage, low grade fever, headache, chills, nausea, malaise or even abdominal pain may occur.

- **Signs**—within few days of indolent primary lesion, often papules or vesicle develop at the site of injury.
- **Lymphadenitis**—within one to three weeks, lymphadenitis develops. The nodes are painful and may be several centimeter in diameter. The overlying skin may be inflamed. The lymph nodes gradually become soft and fluctuant, owing to necrosis and suppuration. The lymphadenopathy may persist for one to six months. In dental point of view, there may be involvement of preauricular, submaxillary or cervical chain of nodes.
- **Parotid pain**—when scratch occur in parotid area, infection may become localized parotid lymphoid tissue causing significant parotid pain.
- **Oculoglandular syndrome of Parinaud**—it consist of conjunctival granuloma with pre-auricular lymphadenopathy. It occurs when person touches fur moistened with cat saliva during cleaning. In this case, person touches the eye organism may get transfer into conjunctiva.
- **Others feature**—other manifestations includes non-pruritic macular or maculopapular rash, thrombocytopenia, pneumonia, conjunctivitis and grand mal seizure.

Diagnostic Criteria

Out of the following four, three should be positive for the diagnosis of cat scratch disease:

- Contact with cat with presence of scratch. Dermal and ocular lesion should be present.
- Negative results for other cause of lymphadenopathy.
- Characteristic histopathological finding of staining of pleomorphic bacilli.
- Positive cat scratch disease skin test (no longer widely used).

Management

- **Self limiting**—the disease has a benign course and it is self limiting.
- **Symptomatic treatment**—symptomatic treatment is given in the form of analgesic.
- **Antibiotics**—erythromycin is first choice of antibiotics. Another antibiotic which can be given is Doxycycline.
- **Node aspiration and drainage**—aspiration of the nodes should be done with needle tunneled laterally in the node.

Tularemia

It is also called as 'Rabbit fever'. It is caused by gram negative bacillus *Francisella tularensis*. It is contacted through infected rabbits, muskrats, ground squirrels and other wild germ, particularly of rodent family.

Types

- Cutaneous
- Ophthalmic
- Pleuropulmonary
- Oral
- Abdominal

Clinical Features

- **Incubation period**—incubation period is up to seven days.
- **Symptoms**—patient complaint of sudden headache, nausea, bony pain, profuse sweating, vomiting, chills and fever.
- **Suppurative ulcer**—a single cut or sore on the skin develops into a suppurative ulcer.
- **Lymph nodes**—lymphatic vessels become swollen and painful and the lymph nodes are remarkably enlarged.
- **Eyes**—the eyes also become involved with conjunctivitis developing through localization of disease in the conjunctival sac.
- **Complications**—tularemia pneumonia and pleuritis are complications of this disease.

Oral Manifestations

- **Cause**—primary infection of the mouth usually occurs from eating infected meat.
- **Site**—it is common on soft palate, tongue, gingiva and angle of mouth.
- **Symptoms**—severe pain is major complaint of the patient.
- **Diphtheria-like appearance**—the appearance of the ulcer is shallow with whitish fibrinous pseudomembrane formation. The tonsil, posterior pharyngeal wall, soft palate, base of the tongue and buccal mucosa may be covered by a grayish white membrane simulating the appearance of diphtheria.
- **Generalized stomatitis**—there may be generalized stomatitis.
- **Regional lymph nodes**—regional lymphadenitis may arise in submaxillary and the cervical groups of nodes. Cervical lymph nodes are tender, enlarged and may suppurate.

Diagnosis

- **Clinical diagnosis**—severe pain with ulcer with systemic symptom of headache, fever may give clue to the diagnosis.
- **Serology**—an agglutination test is used to demonstrate a rising titer of antibody in the serum of patients of *F. tularensis*.
- **Skin testing**—intradermal injection of an extract of *F. tularensis* gives a positive delayed hypersensitivity reaction in 1st or 2nd week of illness.

Management

- **Antibiotics**—antibiotics of choice are streptomycin and tetracycline, either alone or in combination.

Tetanus

It is also called as 'lock jaw'. It is a disease of nervous system characterized by intense activity of motor neurons and resulting in severe muscle spasm.

Pathogenesis

- **Organism responsible**—it is caused by anaerobic gram positive bacillus *Clostridium tetani*.
- **Production of toxins**—the spores of above organism germinated under the anaerobic condition. This will result in production of exotoxin, tetanospasmin and hemolysis.
- **Toxins reach the brain**—all of the above toxins reach the brainstem and anterior horn of spinal cord via bloodstream.
- **Increase muscle tone**—toxin increases muscle tone and rigidity resulting in muscle spasm and convulsion.

Transmission

- **Injury**—it can enter the body through the most trivial injury.
- **Intravenous drug user**—it is often reported amongst intravenous drug users.
- **Contamination**—it is transmitted through contaminated soil, dust or wood splinters.
- **Tetanus neonatorum**—infection of the cut surface of umbilical cord or circumcision wound, due to use of unclean instruments or dressing, may result in tetanus of the newborn which is called as 'tetanus neonatorum'.

Types

- **Local tetanus**—muscle spasm at the site of entry is known as local tetanus.
- **Generalized form**—this type of tetanus involve many system of the body.
- **Cephalic form**—this type of tetanus occurs in association with facial palsy.
- **Neonatal form**—this occurs in infant and route of transmission is from mother.
- **Chronic form**—the cause of it is due to the persistence of focus of infection and fibrosis from inadequately controlled spasms.

Clinical Features

- **Age and sex**—it is more common in young males during their accident prone years.

- **Incubation period**—the clinical manifestations occur within 14 days after incubation period.
- **Local tetanus**—it is characterized by muscle spasm near the site of entry of bacilli. In some cases, it may proceed to generalized form. Mortality rate is less than 1% in this form.
- **Cephalic form**—in this, bacilli are introduced through the wounds in the head and neck region. *Cranial nerve palsy* occurs with cranial nerve, most commonly the 7th cranial nerve.
- **Generalized form**—entire body may be affected with contraction of all groups of somatic muscles leading to characteristic *opisthotonos* (spine become arch shaped). Reflex spasm frequently develops after stimuli. The temperature is usually raised due to increase metabolic rate. When spasm of intercostal, pharyngeal and diaphragmatic muscle occurs, adequate ventilation becomes impossible and the resultant anoxia causes death. Death in patients with tetanus is generally related to pulmonary complications including broncho-pneumonia and pulmonary embolism.
- **Neonatal tetanus**—the incubation period of neonatal tetanus is 3-10 days. It has high fatality rate. The disease is characterized by difficulty in suckling and excessive crying in early stage. As the disease progresses, variable degree of muscular spasm develops. Death is usually due to inadequate ventilation and asphyxia.
- **Chronic tetanus**—it may persist for many years. Clinically, there are features of generalized tetanus to intermittent spasm of individual muscles.

Oral Manifestation

- **Rigidity of muscle of mastication**—this is usually first manifestation of tetanus.
- **Risus sardonicus**—rigidity of facial muscles may occur, producing the typical 'risus sardonicus'. In this, corners of mouth are drawn back with protruded lip, wrinkling of forehead not possible.
- **Symptoms**—patient complaint of difficulty in chewing, swallowing and inability to insert denture.
- **Lock jaw**—as spasm of muscle of mastication increase jaw is locked and mouth cannot be open.

Diagnosis

- **Clinical diagnosis**—lock jaw with risus sardonicus and opisthotonus will give clue to the diagnosis.

Management

- **Antitoxin**—neutralizing the toxin is achieved by administered of human tetanus immunoglobulin. Specific therapy includes immediate intravenous injection of immune serum containing 20,000 IU of antitoxin.

- **Penicillin**—1,000,000 units of penicillin G intravenously, every 6 hours, for 10 days must be administered to kill vegetative form of *Clostridium tetani*.
- **Sedation**—sedation of patient should be done with diazepam.
- **Supportive care**—supportive care includes providing proper nutrition.

Rhinoscleroma

It is unusual chronic infection caused by bacillus *Klebsiella rhinoscleromatis* and it is common in Europe and central and South America.

Clinical Features

- **Age and sex**—both sexes are equally affected. Common between the ages of 20 to 40 years.
- **Site**—usually found in upper respiratory tract, often originating from nose, but involvement of lacrimal glands, orbit, skin, paranasal sinus and intracranial invasion have been described.
- **Rhinitis stage**—in this stage, there is nasal obstruction, nasal deformity and epistaxis. There is also swelling of upper lip and sore throat.
- **Infiltrative stage**—it is characterized by nasal obstruction, due to the presence of exuberant granulation tissue. Hoarseness results due to laryngeal involvement. Anesthesia of soft palate is common in this stage.
- **Nodular stage**—the proliferation of nasal masses may produce configuration known as 'Hebra nose'. Posterior extension of the lesion may produce laryngeal and tracheal obstruction of varying degrees. Complications include scleromatous infiltration of eustachian tube and unilateral scleroma of maxillary sinus.

Oral Manifestations

- **Site**—it is common on lip, soft palate, and tonsil.
- **Appearance**—they appear as proliferative granulomatous lesion of lip, soft palate and tonsil.
- **Symptoms**—there is anesthesia of soft palate, impaired taste, upper lip and uvula enlargement.

Diagnosis

- **Clinical diagnosis**—hebra nose with rhinitis and enlargement of lip, and anesthesia of soft palate will give clue to the diagnosis.

Management

- **Antibiotics**—it should be given to control infection.

Granuloma Inguinale

It is also called as '*granuloma venereum*' and '*donovanosis*'. It is found in inguinal and anogenital region and is caused by *Calymmatobacterium granulomatis* a gram negative bacillus with prominent polar granules. It is chronic slowly progressing, mildly contagious disease.

Clinical Features

- **Age and sex**—it chiefly affects adult black of either sex, but may occur in any race.
- **Appearance**—lesion begins as a small papule that ulcerates, increases in size and eventually gives rise to velvety, beefy, granulating and spreading ulcerative lesion of inguinal and anogenital region.
- **Pseudo-bubo**—inguinal ulceration is commonly secondary to the genital lesion and arises initially as fluctuant swelling known as pseudo-bubo.
- **Metastasis**—metastatic spread to bone and soft subcutaneous tissue has been reported.

Oral Manifestations

- **Cause**—oral lesion appears to be the most common extra-genital form of granuloma inguinale. Oral lesions occur either as a result of autoinoculation through infected fingers or through oral coitus.
- **Site**—it is most commonly found on lips, buccal mucosa or palate or they may diffusely involve the mucosal surface
- **Lip**—lesions of lip are characterized by extensive superficial ulceration with well defined elevated, granulomatous margins.
- **Multiple sinus**—long standing lesion is associated with multiple extraoral sinuses.
- **Types**—may be of three types, i.e. ulcerative, exuberant and cicatricial.
 - **Ulcerative**—it is painful, extensive with punched out appearance. It has got smooth red base with tendency of bleeding from the lesion.
 - **Exuberant**—it appears as proliferative granular mass. The surface of the lesion is rough due to projection. It has got sharp border and lesion are multiple. The mucous membrane is inflamed and edematous.
 - **Cicatricial**—fibrous scar formation may become extensive in nature.

Diagnosis

- **Clinical diagnosis**—ulcerative lesion in the oral cavity which can be multiple and exuberant in variety, will give clue to the diagnosis.

- **Laboratory diagnosis**—Donovan bodies present in smears which are recognized as large, gram negative oval bacteria with intense bipolar staining (*safety pin appearance*). There is granulation tissue with infiltration of polymorphonuclear leukocytes and plasma cells.

Management

- **Antibiotics**—azithromycin is the drug of choice. It should give intermittently. Treatment should continue until healing is complete which usually takes 2-3 weeks.
- **Wound debridement**—in chronic cases, wound debridement followed by antibiotics therapy is helpful.
- **Plastic surgery**—plastic surgery is needed for correction of extensive scarring.

Lymphogranuloma Venereum

It is a venereal disease caused by one of the three strains of *Chlamydia trachomatis*.

Clinical Features

- **Incubation period**—incubation period is 10 days.
- **Symptoms**—there may be fever, chills, headache and malaise.
- **Signs**—it persists as firm, tender enlargement of inguinal lymph nodes. Nodes are tender and adherent to the underlying tissues.
- **Groove sign**—enlargement of lymph nodes both above and below the inguinal ligament, is characteristic feature called as 'groove sign'.
- **Overlying skin**—overlying skin becomes reddened and dusky and multiple purulent fistulae develop over enlarged glands.
- **Females**—in females, placenta is frequently involved. Marked scarring and local edema frequently develops secondary to suppurative lymphadenitis.

Oral Manifestations

- **Causes**—results due to orogenital contact or anti-inoculation.
- **Site**—tongue is the most common site.
- **Appearance**—lesion consists of small, slightly painful superficial ulceration with non-indurated borders which appear on lip.
- **Signs**—in long standing infection, there is zone of cicatricial refraction, dark red area with loss of superficial epithelium, or opaque lichenoid grayish papules.
- **Tongue enlargement**—tongue may become enlarged with areas of scarring and grooves on its dorsal surface.
- **Associated symptoms and signs**—dysphagia, red soft palate and small red granulomatous lesions accompanied by

regional lymphadenopathy are commonly associated symptoms.

- **Lymph nodes**—cervical lymphadenopathy is present. Skin covering the swollen nodes is violaceous and indurated usually with one or more draining sinuses.

Diagnosis

- **Clinical diagnosis**—groove signs with tongue enlargement with scarring will give clue to the diagnosis.
- **Laboratory diagnosis**—lymph nodes biopsy will show minute intracellular cocci.

Management

- **Antibiotic therapy**—it consists of macrolides, tetracycline, and fluoroquinolones.
- **Surgical management**—surgical treatment of bubos and secondary scarring.

Myiasis

It is referred to the invasion of living tissues by the larvae of certain species of flies. Myiasis, the term first introduced by Hope (1840), refers to the invasion of living tissues of humans or other mammals by the eggs or larvae (maggots) of *Diptera* (two winged) flies.

Predisposing Factors

- **Poor oral hygiene**—it has been associated with poor oral hygiene, such as in mouth-breathers, thumb-suckers.
- **Mentally retarded person**—it is common in mentally retarded persons.
- **Cerebral palsy and hemiplegia**—this person cannot maintain normal lip closure or normal level of oral care.

Pathogenesis

- **Organism responsible**—myiasis is caused by members of the *Diptera* (two winged fly) family that lay over 100 to 500 eggs at a time—on food, necrotic tissue, open wounds and unbroken skin and mucosa.
- **Life cycle of larva**—the eggs hatch to become maggots in less than 1 week and the life cycle is completed when the maggots turn into flies in about 2 weeks.
- **Obtaining the nutrition**—the larvae obtain their nutrition from the surrounding tissues and burrow deeper into the soft tissues by making tunnels separating the gingiva and mucoperiosteum from the bone. Necrotic tissue, present in advanced periodontal diseases will form a good substrate in which the fly can lay its eggs. The periodontal pockets provide the eggs a warm and moist environment for further development.

Types

- *Cutaneous or dermal myiasis*—it affects skin.
- *Myiasis of external orifices*—it includes nasal, oral, vaginal and anal myiasis.
- *Myiasis of internal organs*—it includes intestinal and urinary myiasis.

Clinical Features

- *Cutaneous myiasis*—it is characterized by papular or migratory lesions.
- *Symptoms*—papular lesions are itchy and occasionally painful.
- *Open lesions*—open lesion may produce serious discharge and larvae may be detected through the opening (**Fig. 30-12**).
- *Migratory lesions*—migratory lesions are superficial, red tunnel-like lesions, which form creeping eruptions.

Fig. 30-12: Discharge seen from open lesion in oral myiasis.

Oral Manifestation

- *Incidence*—oral myiasis is a rare condition.
- *Appearance*—it presents as an erythematous, edematous or granulomatous lesion.
- *Symptoms*—itching or pain may be present.
- *Signs*—these lesions may pulsate with movement of larvae. An opening is present from which larvae can come to surface of the lesion (**Figs 30.13A and B**).

Diagnosis

- *Clinical diagnosis*—it is easy to make clinical diagnosing by observing larvae in the lesion.

Management

- *Irrigation*—irrigation of the tissue with hydrogen peroxide will come larvae out the lesion (**Fig. 30-14**). Treating the defect with ether, mercuric chloride, or turpentine oil, this irritates the parasites forcing them to

Figs 30.13A and B: Larvae seen in lesion of oral cavity (Courtesy Dr Bhaskar Patle).

Fig. 30-14: Larvae seen in the plate which are removed after patient given hydrogen peroxide (Courtesy Dr Bhaskar Patle).

come out. Whitehead varnish pack, which contains ether, can be applied to the raw wound for protection during the healing phase.

- **Surgery**—surgical removal of larvae should also be done.
- **Intestinal myiasis**—intestinal myiasis may require purgation with sodium sulphate or antihelminthics.

Definition

Viruses have been defined as submicroscopic entities which reproduce within the specific living cells. Virus may contain either ribonucleic acid (RNA) or deoxyribonucleic acid (DNA).

Classification

RNA Virus

Orthomyxovirus

- Influenza

Paramyxovirus

- Measles (rubeola)
- Mumps

Rhabdovirus

- Rabies
- Hemorrhagic fever

Arenavirus

- Lymphocytic choriomeningitis
- Lassa fever

Calicivirus

Coronavirus

- Upper respiratory infection

Bunyavirus

Picornavirus

- Poliomyelitis
- Coxsackie diseases
- Common cold
- Foot and mouth disease
- Encephalomyocarditis

Reovirus

Togavirus

- Rubella
- Yellow fever
- St. Louis encephalitis

Retrovirus

DNA Virus

Herpes virus

- Herpes simplex I (herpes stomatitis and herpes labialis) or HHV 1
- Herpes simplex II (genital lesion) or HHV 2
- Herpes zoster (chicken pox and shingles) or HHV 3
- Epstein-Barr virus (EBV) (infectious mononucleosis, hepatitis, oral hairy leukoplakia and nasopharyngeal carcinoma) or HHV 4
- Cytomegalovirus (infectious mononucleosis, hepatitis) or HHV 5
- Human herpes virus -6 (roseola infantum, otitis media, encephalitis) or
- Human herpes virus -7 (roseola infantum)
- Human herpes virus -8 (infectious mononucleosis, febrile exanthema, Kaposi's sarcoma)
- Simian herpes virus B (mucocutaneous lesions, encephalitis)

Pox virus

- Small pox
- Molluscum contagiosum

Adenovirus

- Pharyngoconjunctival fever
- Epidemic keratoconjunctivitis

Parvovirus

Iridovirus

Papovavirus

- Human warts or papillomas
- Tumorigenic virus in animals

Infections Caused by Viruses

Herpes Simplex Infection

HSV is ubiquitous virus. It is the most common viral disease affecting men. Initial infection may be acquired from eyes, skin and mucosa with infected secretion. After acquiring

the infection, all herpes viruses remain latent in host neural cells, thereby evading host immune response.

Epidemiology

- *HSV I*—this virus mainly affect the region above the waist.
- *HSV II*—in this case, infection occurs below the waist usually in the genital lesion. But nowadays due to increased oral sex, HSV II is found in the oral lesions. Both HSV I and II can be transmitted sexually.
- *Occurrence*—it occurs in early childhood. Preschool period is more prone due to frequent exchange of salivary and nasal secretions.

Pathogenesis Oral Herpes

- *Primary infection*—the virus enters the skin or mucous membrane and reproduces. During this stage, oral signs and symptoms, such as fever, may develop. The virus may cause asymptomatic infections. Asymptomatic infection occurs twice as often as symptomatic disease.
- *Latency*—from the infected site, the virus moves to nerves in the region. There the virus reproduces and becomes inactive.
- *Recurrence*—during certain stresses, emotional or physical, the virus may reactivate and cause new signs and symptoms.

Types

- *Herpetic genitalis*—it is caused by HSV-II and is common in uterine cervix, vagina, vulva and penis. Lesions are more likely to occur on well keratinized areas such as shaft of penis but may progress, more or less rapidly, into superficial erosions that are very painful when touched or contaminated with urine. Urethra may be involved and extremely painful dysuria may develop, especially in women. Regional lymphadenopathy, fever, malaise and anorexia may develop.
- *Genital herpes in HIV patients*—the lesion of genital herpes in immunocompromised patients and HIV infected patients are larger, deeper and are likely to persist and release of virus for periods as long as 30 days. Antibodies to the virus develop 4 to 6 weeks after primary infection.
- *Herpetic meningoencephalitis*—this is serious form characterized by sudden fever and symptoms of increased intracranial pressure. Paralysis of various muscle groups with convulsion and even death may occur.
- *Herpetic conjunctivitis*—swelling and congestion of palpebral conjunctiva, keratitis and corneal ulceration. Recurrent lesions can lead to serious corneal scarring, which may produce blindness.
- *Herpetic eczema* (Kaposi varicelliform eruption)—it is epidermal form of herpetic infections superimposed

upon a pre-existing eczema and is characterized by diffuse vesicular lesions of skin. The patient usually exhibits a high fever coincident with typical umblicated vesicles as well as other systemic manifestation.

- *Disseminated herpes simplex infection of newborn*—it is uncommon and they acquired it during passage through the birth canal of mother suffering from herpetic vulvovaginitis. The newborns exhibit a wide variety of signs and symptoms of the disease and with few exceptions; die on the ninth or twelfth day of life.
- *Herpetic whitlow*—this is the infection of finger by herpes virus through the break in the skin. Dentist may experience primary lesion of fingers from contact with lesions of the mouth or saliva of the patients who are asymptomatic carriers of HSV; called as 'herpetic whitlow'.
- *Herpes gladiatorum or Scrumpox*—infection of skin spreads through the sport of wrestling.
- *Oral infection*—in the oral cavity, there may be *primary infection* (person who is without circulating antibodies) and *recurrent infection* (circulating antibodies are already present).

Primary Herpes Simplex Infection

It is also called as 'acute herpetic gingivo-stomatitis', 'herpes labialis', 'fever blister', 'cold sore' and 'infectious stomatitis'. It occurs in patients with no prior infection with HSV-1. HSV reaches nerve ganglion supplying the affected area, presumably along nerve pathways and remains latent until reactivated. The usual ganglion involved is the trigeminal for HSV-1 and lumbosacral, for HSV-2.

Transmission

- *Close contact*—it occurs during close personal contact, in which exchange of saliva or other secretion happened.
- *Newborn infection*—primary infection of newborn is believed to be caused by vaginal secretions during birth, which results in viremia and disseminated infection of brain, liver, adrenals and lungs.
- *Socioeconomic status*—incidence varies according to socioeconomic group. Person who is having lower economic status will have earlier exposure.

Clinical Features

- *Age*—it develops in both, children and young adults. It can be seen in high school and college students where it is transmitted by kissing and sexual contact.
- *Incubation period*—incubation period is 5 to 7 days.
- *Prodromal symptoms*—prodromal symptoms precede local lesion by 1 to 2 days and it includes fever, headache, malaise, nausea, vomiting and within a few days, mouth

becomes painful. There is also irritability, pain upon swallowing and regional lymphadenopathy.

- **Location**—this lesion mainly occurs on the hard palate, attached gingiva and dorsum of tongue. In some cases, lesion may be presented on the skin (**Fig. 31-1**).

Fig. 31-1: Showing skin lesion of herpes infection (Courtesy Dr Sanjay Pincha).

- **Appearance**—after this, small vesicles, which are thin walled, surrounded by inflammatory base are formed (**Fig. 31-2**). They quickly rupture leaving small, shallow, oval shaped discrete ulcers.
- **Size**—the individual ulcer differs in size from 2-6 mm. As the disease progresses, several lesions may coalesce, forming larger, irregular lesions.
- **Base**—the base of the ulcer is covered with grayish white or yellow plaque.
- **Margins**—the margins of the sloughed lesions are uneven and are accentuated by bright red rimmed, well demarcated, inflammatory halos.

Fig. 31-2: Intact vesicle seen in herpes simplex infection which is thin walled (Courtesy Dr Chole).

- **Lips**—in severe cases, excoriation involving the lips (**Fig. 31-3**) may become hemorrhagic (**Fig. 31-4**) and matted with serosanguinous fibrin-like exudate and parting of the lips during mastication and speech may become extremely painful and difficult.

Fig. 31-3: Lip lesion seen along with marginal gingivitis (Courtesy Dr Chole).

Fig. 31-4: Excoriation of lip with hemorrhagic lesion seen in herpes infection.

- **Acute marginal gingivitis**—appearance of generalized marginal acute gingivitis is typical feature of herpes simplex infection. Entire gingiva is edematous and swollen and small gingival ulcers are seen (**Fig. 31-5**).
- **Pharynx**—examination of posterior pharynx reveals inflammation causing difficulty in swallowing.
- **Lymph nodes**—cervical and submandibular lymphadenopathy is present.

Fig. 31-5: Acute marginal gingivitis present in the case of herpes simplex infection (Courtesy Dr Chole).

- **Healing**—the disease is self limiting and lesions begin healing in a week to 10 days and leave no scar.
- **Herpes simplex infection of adults**—it is seen in patients who do not acquire HSV infection and immunity during childhood. In such cases, primary herpes simplex infection is often acquired via new sexual partner and primary HSV gingivostomatitis and pharyngitis can occur. It occurs usually due to HSV I (Figs 31-6A and B)
- **Histopathological finding**—Lipschutz bodies can be seen in HSV infection. In cytologic study, there is presence of multinucleated giant cells, and ballooning degeneration of cells.

Recurrent or Secondary Herpetic Infection

In some cases, HSV may remain latent in epithelium which is the main cause of recurrent infection with HSV. In this case, HSV reactivated at the latent site it moves centrally to the mucosa. When reactivation is triggered, they spread along the nerves to different sites on oral mucosa and skin, destroy the epithelial cells and induce the typical inflammatory response with characteristic lesions of recurrent infection.

Types

- **Recurrent herpes labialis (RHL)**—If it occurs on lip, it is called as recurrent herpes labialis.
- **Recurrent intraoral herpes simplex infection (RIH)**—If occurs intraorally it is called as recurrent intraoral herpes infection.

Precipitating Factors

- **Surgery**—when any surgery which involve trigeminal ganglion, recurrent infection with herpes can occur. The

A

B

Figs 31-6A and B: Primary infection occurring in adult patient. (A) Ulcer seen with acute marginal gingivitis and (B) Large ulcer seen on the tongue.

reason for this is herpes virus remain latent in trigeminal ganglion.

- **Immunity**—low serum IgA, decreased cell mediated immunity, decreased anti-herpes activity and depression of ADCC (antibody dependent cellular cytotoxicity) and interleukin-2, caused by prostaglandin release in skin can precipitate the attacks.
- **Trauma**—trauma to lips, dental extraction can lead to recurrent infection.
- **Infection**—in some cases, upper respiratory tract infection can trigger the herpes infection.
- **Others**—fever, emotional upset, sunburns, fatigue, menstruation, pregnancy and allergy can be some precipitating factors for herpes infection.

Clinical Features

- **Occurrence**—recurrent herpes simplex infection may occur at widely varying intervals, from nearly every

month in some patients to only about once a year or even less in others.

- *Prodromal symptoms*—in either location, lesion is preceded by tingling and burning sensation and feeling of tautness, swelling or slight soreness subsequent development of vesicle.
- *Signs*—it is accompanied by edema at the site of the lesion, followed by formation of clusters of small vesicles.
- *Recurrent herpes labialis*—these gray or white vesicles rupture quickly leaving small red ulcerations, sometimes with slightly erythematous halo on lip covered by brownish crust on lips (**Fig. 31-7**). Sizes range from 1 to 3 mm in diameter, to 1 to 2 cm. But sometimes, it is large enough to cause disfigurement (**Fig. 31-8**).

Fig. 31-7: Recurrent herpes labialis showing vesicle of the lip (Courtesy Dr Amit Parate).

Fig. 31-8: Extensive lesion of herpes labialis showing disfigurement (Courtesy Dr Amit Parate).

- *Recurrent intraoral herpes*—in recurrent intraoral herpes (RIH) vesicles break rapidly to form small red ulceration, sometimes with slight erythematous halo. Cluster of

small vesicles or ulcers 1 to 2 mm in diameter are commonly found on gingivae, tongue (**Fig. 31-9**) palate and alveolar region.

Fig. 31-9: Recurrent intraoral, herpes infection seen on the tongue (Courtesy Dr Amit Parate).

- *Healing*—the lesions gradually heal within 7-10 days and leave no scars.
- *Complication*—herpes simplex infection can lead to development of extra-genital lesions, CNS complications and vaginal fungal super infections.

HSV in Immunocompromised Patient

It is described in *Chapter 35: AIDS*.

Diagnosis

- *History*—negative past history of recurrent herpes labialis and a positive history of close contact with a patient with primary or recurrent herpes is helpful in making the diagnosis.
- *Typical clinical features*—patient is easily diagnosed as having primary herpetic gingivostomatitis; if he/she presents with typical clinical features of generalized symptoms followed by eruption of oral vesicles and acute marginal gingivitis and does not have history of recurrent herpes.
- *HSV isolation*—isolation and neutralization of virus in tissue culture is most positive method of identification. Rabbit kidney and human amnion are sensitive to HSV.
- *Antibody titer*—antibodies to HSV appear in a week and react peak in 3 weeks.

Differential Diagnosis

- *Hand-foot and mouth disease*—in this case, lesions are not clustered and gingiva is not affected. Lesions can also be seen on feet and hand.

- *Herpangina*—oropharyngeal and soft palate involvement is more prominent. It affects children in late summer and early monsoon season on soft palate and facial area with fever and malaise.
- *Chronic recurring aphthae*—no stomatitis, no general systemic symptoms and lesions are less numerous and more often found in adults.
- *Herpes zoster*—segmental distribution along the anatomical location of nerve.
- *Erythema multiforme*—it occurs in young adults, as compared to herpes simplex which occurs in children. Gingivitis is not severe and generally limited to anterior part of the mouth. In erythema multiforme skin lesions are present.
- *Bullous lichen planus*—it is painful condition characterized by large blister on tongue and cheek with rupture and it undergo ulceration.
- *Cheilitis granulomatous*—edema appears suddenly without prodromal symptoms and recurrence is absent.
- *Benign mucosal pemphigoid*—no prodromal symptoms; with progression from erythema to swelling to blister to crusting.
- *Allergic contact dermatitis*—sudden appearance with allergen proof.

Management

Primary herpes simplex infection

Symptomatic

- *Pain control measures*—topical anesthetics like 2% lidocaine, 0.1% diclonine hydrochloride, 0.5% benzocaine hydrochloride are used. Solution of diphenylhydramine hydrochloride (*Benadryl*) 5 mg mixed with equal amount of milk of magnesia can also reduce the pain. In some cases systemic administration of analgesics is also given.
- *Topical anti-infective agents*—it is given to prevent secondary infection. Agents used are 0.2% chlorhexidine gluconate, tetracycline mouth wash and elixir or diphenylhydramine.
- *Supportive care*—fluid is given to maintain proper hydration and electrolyte balance. Antipyretics can also be given to control the fever.
- *Good oral hygiene*—oral hygiene should be properly maintained to avoid any secondary infection.

Specific

- *Acyclovir*—it inhibits DNA replication in HSV infected cells reducing the duration of illness but with few side effects. The optimum oral dosage of acyclovir is 1,000 to 1600 mg daily, for 7 to 10 days. It should be ideally given in a dose of 15 mg/kg five times a day.
- *Valacyclovir*—it is prodrug of acyclovir and it has far better biocompatibility as compared to acyclovir. It should be used in combination with famciclovir.

Recurrent herpes simplex infection

- *Minimized obvious trigger*—recurrent infection can be suppressed by reducing trigger factors. This can be done by applying the sunscreen lotion to lip.
- *Topical antiviral medication*—topical antiviral medication like 5% acyclovir cream, 3% penciclovir cream, 10% docosanol cream are effective. It should be applied three to six times daily.
- *Topical ammonium chlorides*—nowadays, recent formulation of quaternary ammonium chloride, dimethyl carbonal is used and has been marketed. But it is not scientifically proved to be effective so its use not recommended.
- *Systemic antiviral medication*—usually Valacyclovir or famciclovir (500-1000 mg three times daily) should be given.
- *Topical carbon oxolone*—it is useful in some cases of herpetic gingivostomatitis.

Varicella Zoster Infection

It is an acute disease caused by varicella zoster virus, which is a DNA virus similar to HSV and causes both, primary and recurrent infection. After primary disease is healed, VZV becomes latent in the dorsal root ganglion of spinal nerve or extramedullary ganglion of cranial nerve. VZV becomes reactivated causing lesions of localized herpes zoster. Patients with HIV infection, leukemia and those on immunosuppressive therapy have an increased susceptibility to severe or potentially fatal herpes zoster. Herpes zoster infection can be deep seated and disseminated causing pneumonia, meningoencephalitis and hepatitis.

Forms

- *Chickenpox (Varicella)*—it is primary infection with zoster virus.
- *Shingles (herpes zoster) or zona*—it is recurrent infection with zoster virus. It increases with age and occurs in immunocompromised patient. It can be seen in AIDS patient.
- *Postherpetic neuralgia*—it is neuropathic disease resulting from peripheral and central nervous injury by zoster virus.
- *James Ramsay Hunt syndrome*—it is zoster infection of geniculate ganglion.

Chickenpox

It is also called as 'varicella'. It is an acute viral disease occurring in children and most commonly in winter and spring months.

Clinical Features

- *Incubation period and mode of transmission*—incubation period is two weeks and mode of transmission is by air borne droplet or direct contact with infected persons, with the probable port of entry being respiratory tract.
- *Age*—it is seen in first two decade of life.
- *Prodromal symptoms*—it is characterized by prodromal occurrence of headache, nasopharyngitis and anorexia, followed by maculopapular or vesicular eruptions on skin and low grade fever.
- *Location*—these eruptions usually begin on the trunk and spread to involve the face and extremities.
- *Onset*—there is development of a pruritis, maculopapular rash followed by vesicle.
- *Dewdrop on rose petal*—there is classic presentation of centrally located vesicle surrounded by zone of erythema. This is called as *dewdrop on rose petal* appearance (Fig. 31-10). They occur in successive crops so many vesicles in different stages of formation or resorption may be found.
- *Healing*—the skin eventually ruptures, forming a superficial crust and heals by desquamation. The disease runs its clinical course in a week to ten days, seldom leaving any after effects.
- *Secondary infection*—occasionally, secondary infection of vesicle results in the formation of pustules which may leave small pitting scar upon healing.
- *Complication*—it includes cerebellar ataxia, encephalitis, pneumonia, myocarditis, Reye's syndrome, sickle cell crisis, hemolytic anemia and hepatitis.
- *Neonatal chickenpox*—this occurs due to infection in pregnancy. This infection may lead to congenital defect in the newborn.
- *Diagnosis*—it is made by virus isolation and typical exanthema present.

Fig. 31-10: Dewdrop like vesicle formation seen on the abdomen of the patient (Courtesy Dr Pincha).

Oral Manifestation

- *Site*—small blister-like lesions occasionally involve the oral mucosa chiefly buccal mucosa, tongue, gingiva, palate as well as the mucosa of pharynx.

- *Appearance*—the mucosal lesion, initially a slightly raised vesicle with a surrounding erythema, ruptures soon after formation and forms a small eroded ulcer with red margins (Fig. 31-11), closely resembling aphthous lesion.

Fig. 31-11: Intraoral ulceration seen in case of chickenpox infection (Courtesy Dr Sanjay Pincha).

Management

- *Pain control*—patient should be managed with all pain control method which is described in herpes simplex infection. Aspirin is contraindicated as it can lead to Reye's syndrome.
- *Control of pruritus*—warm baths with soap or baking soda, application of calamine lotion should be done. As VZV is having lipid envelope, it can destroy by soap and detergent. Systemic diphenhydramine is also given to control pruritus.
- *Antiviral drug*—acyclovir should be used in a dose of 800 mg five times daily. It will reduce the severity of lesion. Another antiviral agents use are valacyclovir (1000 mg TDS) and famciclovir (500 mg TDS) for 7 days should be given.
- *Varicella zoster immune globulin*—this is given in case of immunocompromised patient. This will help to reduce severity of clinical manifestation.
- *Local antiseptic*—at the first sign of secondary infection, a local antiseptic should be applied to the skin. If the bacterial infection progresses, appropriate antibiotics should be prescribed.
- *Prevention by vaccination*—live attenuated VZV vaccine should be given in children at 12 and 18 months of age. It should usually combined with MMR (measles, mumps and rubella).

Herpes Zoster

It is also called as '*shingles*' or '*zona*'. It is an acute infectious viral disease of extremely painful and incapacitating nature, characterized by inflammation of dorsal root ganglion, associated with vesicular eruptions of skin and mucous membrane of the area supplied by the affected sensory nerve.

Predisposing Factors

- **Trauma**—in some cases, trauma in the distribution of trigeminal nerve can lead to herpes zoster infection.
- **Malignancy**—development of malignancy or tumor in the region of dorsal root ganglion can also cause herpes zoster.
- **Radiation**—Local X-ray radiation can also be predisposing factors.
- **Immunosuppressive therapy**—this will lead to reactivation of virus and development of lesion.

Clinical Features

- **Age and sex distribution**—it affects adults and there is no sex predilection.
- **Prodromal symptoms**—prodromal period of 2 to 4 days in which shooting pain, paresthesia, burning and tenderness appears along the course of affected nerve. The reason for shooting pain is occurrence of active ganglionitis with resultant neuronal necrosis and severe neuralgia. The pain is present in the area supplied by the affected nerve (dermatome).
- **Appearance**—unilateral vesicles on an erythematous base appear in clusters, chiefly along the course of nerve and giving picture of a single dermatome involvement (**Fig. 31-12**). This is called as 'zosteriform' pattern.

Fig. 31-12: Intact vesicle seen showing dermatome involvement (Courtesy Dr Pincha).

- **Healing**—vesicle turns into scab in 1 week and healing takes place in 2 to 3 weeks.
- **Nerves**—nerves commonly affected are C₃, T₅, L₁, L₂ and 1st division of trigeminal nerve. It may affect motor nerve.
- **Involvement of 1st division of trigeminal nerve**—involvement of 1st division leads to corneal scarring and blindness (**Fig. 31-14**) which are presumably related to viral spread, neural damage, vasculitis and inflammatory immune response. 1st division involvement also lead to lesion of scalp (**Fig. 31-13**).

Fig. 31-13: Herpes zoster involving scalp of the patient.

Fig. 31-14: Involvement of ophthalmic division showing involvement of eyes (Courtesy Dr Revent Chole).

- **Zoster sine eruptione or zoster sine herpette**—it is zoster infection without appearance of dermatomal lesion.
- **Hutchinson sign**—it is cutaneous zoster infection of the side of tip of nose.

Oral Manifestations

- **Cause of oral lesion**—herpes zoster involving 2nd and 3rd divisions of trigeminal nerve lead to oral manifestation. Involvement of 2nd division leads to lesion of midface and upper lip and involvement of 3rd division leads to lesion of lower face and lower lip.
- **Site**—it may be found on buccal mucosa, tongue, uvula, pharynx and larynx.
- **Symptoms**—patient noticed pain, burning, tenderness usually on the palate on one side.
- **Signs**—after several days of symptoms, intact vesicles (**Fig. 31-15**) appear which soon rupture (**Fig. 31-16**) to leave areas of erosion (**Fig. 31-17**).

Fig. 31-15: Intact vesicle seen on the face by herpes zoster (Courtesy Dr Jitu Sachdeo).

Fig. 31-16: Herpes zoster showing ruptured vesicle in the oral cavity.

Fig. 31-17: Erosion area seen on the palate in case of herpes zoster (Courtesy Dr Chole).

- *Healing*—healing usually takes place within 10 to 14 days (**Fig. 31-18**).

Fig. 31-18: Healed herpes zoster lesion seen on the face (Courtesy Dr Jitu Sachdeo).

- *Teeth*—trigeminal herpes zoster occurring during tooth formation causes pulpal necrosis and internal root resorption. So in the case of herpes zoster, several non-vital teeth can be seen (**Fig. 31-19**). In some cases, osteomyelitis can also develop in the patient.

Fig. 31-19: Multiple non-vital teeth seen 7 years after occurrence herpes zoster (Courtesy Dr Chole).

Diagnosis

- *Clinical diagnosis*—lesions along the distribution of nerve will give clue to diagnosis.
- *Fluorescent antibody testing*—in this test, smear is obtained by scraping the lesion and staining it with fluorescent conjugated monoclonal antibody.

Table 31-1: Difference between herpes zoster and recurrent herpes simplex infection

<i>Herpes zoster</i>	<i>Recurrent herpes simplex infection</i>
Prodromal symptoms—fatigue, hyperesthesia, pain	Prodromal symptoms—tension, burning, itching
Development—edema and erythema, papulovesicular then vesiculopustular lesions and erosion	Development—vesiculoerosive lesion in crops and clusters, but not limited to dermatome
Severe pain	Moderate pain
Lesions limited to the course of a sensory nerve	No skin lesions
Longer course—post-zoster neuralgia	Fast healing without consequence
No recurrence	Recurrent appearance

- **PCR**—Polymerase chain reaction testing is used to detect viral antigen.
- **Biopsy**—it will show multinucleated giant cells.
- **Virus isolation**—this virus is difficult to culture.

Differential Diagnosis

- **Recurrent herpes simplex infection**—described in **Table 31-1**.
- **Herpangina**—acute infection, palatal vault is affected.

Management

- **Antiviral drugs**—acyclovir 800 mg five times daily which is associated with significantly accelerated healing within 48 hours of the onset of rash.
- **Symptomatic treatment**—antipyretic medication with antipruritics diphenhydramine can be administered to decrease itching.
- **Prevention of postherpetic neuralgia**—intralesional steroids and local anesthetic can be used to decrease healing time and to prevent postherpetic neuralgia. But this comes with many side effects and there are some conflicting reports about the efficiency of steroid in control of postherpetic neuralgia.
- **Capsaicin**—topical capsaicin 0.025% four times a day has been suggested for temporary relief of neuralgia following herpes zoster infection. Capsaicin is derived from red peppers. The mechanism of action apparently involves the depletion of substance P in the peripheral sensory neurons causing the skin less sensitive. After treatment patient should wash hand after use and avoid contact with mucosal surface.
- **Tetracycline rinse**—mouth rinsing with tetracycline, three to five times daily, may reduce the pain.

Postherpetic Neuralgia

This is complication of zoster infection.

Etiopathogenesis

- **Peripheral injury**—zoster virus injures the peripheral nerve by demyelination, wallerian degeneration and sclerosis.
- **Central injury**—there is also atrophy of dorsal horn cells in the spinal cord.
- **Infection**—low grade persistent infection of trigeminal ganglion also cause postherpetic neuralgia.

Clinical Features

- **Age and sex distribution**—It affects older age group. Incidence of postherpetic neuralgia is more in women as compared to men.
- **Symptoms**—initially, there is presence of rash which is followed by pain. Pain may continue for weeks to months. If pain occurs more than 6 months of duration is usually called as postherpetic neuralgia.
- **Other symptoms**—there may be paresthesia, hyperesthesia and allodynia. In some cases, there is also presence of sensory deficit.

Management

- **Prevention**—use of live attenuated Varicella zoster vaccine after age of 60 years will reduce the incidence of postherpetic neuralgia. To control postherpetic neuralgia, antiviral drug should be given in early course of disease.
- **Topical therapy**—use of topical agents like lidocaine (anesthetics), capsaicin (an extract of hot chili peppers that depletes the neurotransmitter substance P) should be used.
- **Drug therapy**—the use of TCA (tricyclic antidepressant) like Amitriptyline, nortriptyline, doxepin and desipramine have been used to minimize painful sequelae of this infection. The patient who cannot tolerate TCA due to cardiovascular side effect, the other drug gabapentin and pregabalin should be given. Carbamazepine or phenytoin can also be given to minimize the pain.

- **Surgery**—when drug therapy is ineffective then surgery should be carried out at the level of peripheral nerve or dorsal root is indicated. In some cases, sympathetic nerve block is also effective.
- **Steroid therapy**—steroid injection can be given in a patient with age more than 60 years, for the treatment of post-herpetic neuralgia. This will help in reducing the pain of the patient.

James Ramsay Hunt Syndrome

It is zoster infection of geniculate ganglion with involvement of the external ear and oral mucosa.

The clinical manifestation of it is facial paralysis as well as pain of the external auditory meatus and pinna of the ear.

In addition, vesicular eruption occurs in the oral cavity and oropharynx with hoarseness of voice, tinnitus, vertigo and occasional other disturbances.

Mumps

It is described in Chapter 26: Salivary Gland Disorders.

Measles

It is also called as '*Rubeola*' or '*morbilli*'. It is an acute contagious dermatotropic viral infection, primarily affecting children and occurs many times in epidemic form.

Transmission

- **Droplet infection**—spread of disease occurs by direct contact with a person or by droplet infection, the portal of entry being the respiratory tract.

Clinical Features

- **Incubation period**—incubation period is 8 to 10 days.
- **Prodromal symptoms**—onset of fever, malaise, cough and coryza (running nose).
- **Eye lesion**—there is conjunctivitis, photophobia, lacrimation occurs.
- **Skin lesion**—skin eruption begins on face, in the hair line and behind the ear and spread to neck, chest, back and extremities. They appears as tiny red macules or papules which enlarge and coalesce to form blotchy discolored irregular lesions, which blanch on pressure. Skin lesions fade away in 4 to 5 days with fine desquamation.
- **Complication**—it is the disease which lowers general body resistance and for this, it often leads to complications. Complications include bronchial asthma, encephalitis, otitis media, noma, and Hodgkin's lymphoma.

Oral Manifestations

- **Onset**—oral lesions precede 2 to 3 days before cutaneous rash and are pathognomonic of this disease.
- **Site**—the most common site is on buccal mucosa.
- **Koplik's spots**—intraoral lesions are called as Koplik's spots and occur in 97% of cases (**Fig. 31-20**). They are small, irregularly shaped flecks which appear as bluish white specks surrounded by bright red margins. They are described as '*grains of salt*' on red background.
- **Other features**—there is generalized inflammation, congestion, swelling and focal ulceration of gingiva, palate, and throat may occur.

Fig. 31-20: Bluish white numerous Koplik spots seen in measles.

Diagnosis

- **Clinical diagnosis**—typical clinical features like Koplik spots and history are important diagnostic criteria for measles.
- **Laboratory diagnosis**—it is done by virus isolation and raised antibody titers. Antibodies appear after 3 days of rash.

Differential Diagnosis

- **Small pox**—high fever, monoform exanthema.
- **Chickenpox**—typical exanthema that follows the intraoral lesion. The diagnosis can be established microscopically (blister swab) and virologically.

Management

- **Vaccination**—best treatment for the measles is vaccination. The widely used vaccine is MMR. One injection of live, attenuated measles virus should be given subcutaneously in children over one year. Second dose of vaccine is given in 12 to 15 months.
- **Passive immunization**—human immunoglobulin given intramuscularly is recommended for the prevention and attenuation of measles, particularly for contact under

18 months of age and for debilitated children. The dose is 250 mg for children under 1 year and 500 mg for those over this age.

- *Isolation of patient*—the patient should be isolated, if possible.
- *Symptomatic treatment*—analgesic, anti-pyretic should be given to patient to control pain and fever.
- *Specific drug treatment*—no drug has shown any promising results in the management of measles. Drugs which are tried are ribavirin, interferon, immunoglobulin and vitamin A.

Rubella (German Measles)

Rubella is produced by Togavirus. It is milder infection as compared to measles.

Transmission

- *Droplet infection*—it is transmitted through droplet infection in individual who is living in close living condition.
- *In utero*—infants with congenital infection may be present. It may result in birth defect. Infant born with rubella is called as *congenital rubella syndrome* (CRS).

Clinical Features

- *Incubation period*—incubation time is 14 to 21 days.
- *Prodromal symptoms*—it includes fever, headache, malaise, anorexia, conjunctivitis, coryza, cough and pharyngitis.
- *Lymphadenopathy*—it is seen in suboccipital, postauricular, and cervical chains.
- *Complication*—it includes arthritis, encephalitis and thrombocytopenia.
- *Rash*—the exanthematous rash seen on face and neck. It is discrete pink macule and it fades as it spreads.
- *Congenital rubella syndrome*—it results in deafness, heart disease and cataracts.

Oral Manifestation

- *Forschheimer's sign*—small, discrete, dark red papules seen on soft palate.
- *Petechiae*—petechiae can also be seen on the palate.

Diagnosis

- *Clinical diagnosis*—it is very difficult to establish clinical diagnosis as clinical presentation is mild and subclinical.
- *Laboratory*—serological analysis should be carried out to establish diagnosis.

Management

- *Vaccination*—this has dramatic results after vaccine was released in 1969.
- *Human rubella immunoglobulin*—it is administered to have passive immunity. If it is given within days after the exposure, it will decrease the severity of infection.

Coxsackievirus Infection

They are RNA retroviruses and are named after town in upper New York where they were first discovered. They are divided into 2 groups:

- Type A—24 types
- Type B—6 types

These viruses can cause hepatitis, meningitis, myocarditis, pericarditis and respiratory disease. Three clinical types of infection are important and discuss below. These diseases occur more frequently from June to October (summer and early fall).

Transmission

- *Fecal oral route*—it is major path of transmission. Frequent hand washing will diminish the spread of this virus.
- *Saliva*—virus can spread through saliva during acute condition.
- *Predisposing factors*—overcrowding, poor oral hygiene may aid to infection.

Herpangina

It is also called as '*aphthous pharyngitis*', '*vesicular pharyngitis*'. A₄ causes majority of the cases. A₄ to A₁₀ and A₁₆ to A₂₂ have also been implicated.

Clinical Features

- *Age*—majority affected are young children aged 3 to 10 years.
- *Incubation period*—incubation period is of 2 to 10 days.
- *Site*—it occurs on posterior pharynx, tonsil, faucial pillars and soft palate.
- *Prodromal symptoms*—initially, generalized symptoms of fever, chills, headache, anorexia, prostration, abdominal pain and sometimes vomiting. Sore throat, dysphagia and occasionally, sore mouth can occur.
- *Ulceration*—lesion starts as punctate macule which evolves into papules and vesicles (**Fig. 31-21**). Within 24 to 48 hours, vesicles get ruptured forming small 1 to 2 mm ulcers.
- *Base and margins*—ulcers show a gray base and inflamed periphery.
- *Healing*—they generally heal without treatment in 1 week.

Fig. 31-21: Ulceration seen on posterior part of oral cavity in case of herpangina.

Diagnosis

- *Clinical diagnosis*—lesions are seen posterior part of oral mucosa.

Differential Diagnosis

- *Primary herpes simplex infection*—herpangina occur in epidemic, and HSV does not. Clinical manifestations of herpangina are generally milder than HSV infection. Lesions of herpangina occur in pharynx and posterior portions of oral mucosa and in case of herpes simplex infection, it occur in anterior part of oral cavity. Herpangina does not cause generalized acute, marginal gingivitis which is typical feature of herpes simplex infection.
- *Herpes zoster*—in this, segmental distribution of vesicle is seen which is absent in case of herpangina.

Hand-Foot-and-Mouth Disease

It is caused by A₁₆, A₅, A₇, A₉, A₁₀, B₂ and B₅.

Clinical Features

- *Age*—it primarily affects children between the age of 6 months and 5 years.
- *Symptoms*—there is anorexia, low grade fever, diarrhea, nausea and vomiting.
- *Appearance*—it is characterized by appearance of maculopapular, exanthematous and vesicular lesions of skin, particularly involving the hands, feet, legs, arms and occasionally buttocks.

Oral Manifestations

- *Sites*—the most common sites for oral lesions are hard palate, tongue and buccal mucosa.
- *Symptoms*—a sore mouth with refusal to eat is one of the most common findings in this disease.

- *Appearance*—oral lesions are more extensive than herpangina. The tongue may become red and edematous. Clinical manifestations last for 3 to 7 days.

Diagnosis

- *Clinical diagnosis*—oral lesion in association with skin lesion will aid to diagnosis.

Differential Diagnosis

- *Herpetic gingivostomatitis*—entire oral cavity is affected. No hand and feet involvement.
- *Varicella zoster infection*—segmental distribution along the anatomical location of nerve (unilateral lesions).
- *Herpangina*—affect children mostly in late summer and early monsoon and lesions are common on soft palate and facial area with fever and malaise.
- *Allergic stomatitis*—sudden appearance, no prodromal symptoms with itching and noticeable erythema.
- *Chickenpox*—in addition to intraoral changes, polymorphous exanthema on the entire body and severe lesions.

Acute Lymphonodular Pharyngitis

It is caused by A₁₀ and is same as herpangina. Yellow-white nodules appear that do not progress to vesicles or ulcers. It is self limiting and only supportive care is indicated.

Clinical Features

- *Age*—the disease affects predominantly children and young adults, occasionally older adults can also be affected.
- *Site*—the lesion appears on uvula, soft palate, anterior pillars and posterior oropharynx.
- *Incubation period*—it has got 5 days incubation period and course may run for 4 to 14 days, with local oral lesions resolving within 6 to 10 days.
- *Symptoms*—the chief complain is of sore throat, 41°C temperature, mild headache, anorexia and loss of appetite.
- *Appearance*—it consists of raised, discrete, and whitish to yellowish solid papules of 3 to 6 mm in diameter, surrounded by narrow well defined zone of erythema.
- *Signs*—lesion is non-vascular, non-ulcerated, tender, superficial and bilateral.

Diagnosis

- *Clinical diagnosis*—whitish nodule with sore throat can lead to diagnosis.

Management

- *Symptomatic treatment*—no specific treatment is necessary since the disease is self limiting and generally

regresses within one to two weeks. Symptomatic treatment directed towards giving anti-pyretic and topical anesthetics.

- *Nutritional supplement*—as eating and swallowing is difficult, patient should be given proper hydration.

Infectious Mononucleosis

It is also called as 'glandular fever' or 'mono'. It is a benign acute infectious disease caused due to the Epstein-Barr virus, a herpes virus which infects the B-lymphocytes. It is commonly seen in adolescents and young adults. The mechanism of human transmission is not entirely known but one important mean is thought to be through deep kissing so this condition is also called as 'kissing disease'. EBV is present in oropharyngeal secretions and mixed saliva during active phase.

Clinical Features

- *Incubation period*—it varies from 10 to 40 days.
- *Age*—disease occurs chiefly in children and young adult in 4 to 15 age groups.
- *Symptoms*—the patient usually complaint of sore throat accompanied by fever usually 101°F to 103°F and extreme fatigability. Occasionally, there is a complaint of headache, photophobia, nausea, vomiting, diarrhea and presence of erythematous macular rash (*Morbili-form skin rash*).
- *Signs*—physical examination reveals enlarged palatine tonsils with copious amount of cheesy yellow exudate filling tonsillar crypt. Patient may also be having splenomegaly and hepatomegaly.
- *Lymphadenopathy*—enlargement of the superficial lymph nodes, particularly the posterior cervical are common manifestations. Lymph nodes are slightly tender on palpation.
- *Chronic fatigue syndrome*—this is controversial whether this is associated with EBV infection. In this, patient noticed chronic fatigue, fever, pharyngitis, myalgia, headache, arthralgia, paresthesia, depression and cognitive defect.
- *Complications*—airway obstruction, splenic rupture, progressive neurological involvement and hemolytic anemia.
- *Hematological finding*—there is an increase in white blood cell count.

Oral Manifestations

- *Site*—lesion present on soft palate, labial and buccal mucosa.
- *Petechiae*—it can be seen on soft palate (**Fig. 31-22**). They are transient.

Fig. 31-22: Multiple petechiae seen on soft palate in the patient of infectious mononucleosis.

- *Ulcerative gingivitis, periodontitis and stomatitis*—ulcerative gingivitis, periodontitis and stomatitis may be present and the lesion normality persisting for 3 to 11 days.
- *Tonsils*—intraorally, the most prominent sign is enlargement and inflammation of the tonsils along with sore throat and difficulty in swallowing. Quite commonly the tonsils are covered by a white or grayish pseudo-membrane.
- *Bleeding*—1/3rd of the patients with hemorrhagic tendency exhibit oronasopharyngeal bleeding, including bleeding from gingiva.

Diagnosis

- *Clinical diagnosis*—morbiliiform skin rash with enlarged palatine tonsil with fever can aid in diagnosis.
- *Laboratory diagnosis*—there is positive Paul Bunnell (test for detecting EBV antibody) and mono spot test.

Management

- *Symptomatic*—the oral lesion of infectious mononucleosis is treated symptomatically. A topical anesthetic may be used in painful ulcers and hydrogen peroxide rinses aid in ameliorating the fusospirochetal gingivitis. Patient should be given antipyretic and anti-inflammatory therapy to control fever and pain.
- *Antiviral drugs*—ganciclovir and Alfa interferon inhibit the replication of Epstein Barr virus *in vitro*. Alpha interferon reduces EBV replication and shedding in organ transplant patient.
- *Corticosteroid*—corticosteroids are indicated only in the presence of complications like airway obstruction, progressive neurological involvement, hemolytic anemia. Normally corticosteroid should be avoided.
- *Precaution*—patient should avoid sports as it may lead to splenic rupture.

Cytomegalovirus Infection

This virus is also called as HHV-5. It may be clinically expressed or latent. CMV can remain latent in salivary gland cells, endothelium, macrophages and lymphocytes. Cytomegalovirus (CMV) is a double-stranded DNA virus that is fairly common in the general population, with approximately 60% of people being seropositive but asymptomatic.

Transmission

- *In utero transmission*—infants can acquire it *in utero* from placenta, during delivery. Infant can also acquire infection through breastfeeding.
- *Sexual transmission*—transmission can also occur through exchange of body fluid like saliva, during sexual activity.
- *Blood transfusion and organ transplantation*—blood and transplanted tissues are also potential means of transmission of virus to susceptible individuals.

Clinical Features

- *Neonatal infection*—features of this infection include hepatosplenomegaly, extramedullary cutaneous erythropoiesis, encephalitis and thrombocytopenia. Encephalitis may lead to mental retardation and motor retardation.
- *Adult's infection*—there is fever, malaise, myalgia, abnormal liver function. Petechial hemorrhages can also occur. Patient may also suffer from pneumonia, microcephaly, cerebral calcification and hearing defect.
- *CMV chorioretinitis*—this is commonly seen in AIDS patient. This may lead to blindness of patient.
- *CMV colitis*—this will lead to bloody diarrhea.

Oral Manifestations

- *Salivary gland involvement*—this can occur in immunocompetent patient. Patient usually present with acute sialadenitis which can involve major and minor salivary gland. Affected gland is painful. Patient may suffer from xerostomia.
- *Mucosal ulceration*—oral ulcer occur in patient with CMV disease. It is more commonly seen in AIDS patient.
- *Gingival infection and hyperplasia*—patient may suffer from gingivitis and gingival hyperplasia (**Fig. 31-23**).
- *Dental significance*—susceptible dental personnel may acquire CMV infection in the absence of barrier protection.

Diagnosis

- *Clinical diagnosis*—CMV produces deep, penetrating oral ulcerations on the lips, tongue, pharynx, or any mucosal site.

Fig. 31-23: Gingival infection and ulceration seen in the patient with cytomegalovirus infection.

- *Laboratory diagnosis*—characteristic “owl’s eye” appearance of cellular inclusions during the histologic examination.

Management

- *Prevention*—it should be done by passive immunization with hyperimmune gamma globulin.
- *Antiviral therapy*—no specific antiviral therapy is useful. Foscarnet, ganciclovir and alpha interferon can be used which may yield success in some cases. Intravenous ganciclovir will produce resolution of oral ulceration in most instances.

Foot and Mouth Disease

It is also called as ‘aphthous fever’, ‘hoof and mouth disease’, ‘epizootic stomatitis’. It is a viral infection which rarely affects man, but does affect hogs, sheep as well as cattle. Transmission of this disease occurs through infected animals in human beings, it is usually through milk from infected animals.

It is manifested by fever, nausea, vomiting, malaise and appearance of ulcerative lesions of oral mucosa and pharynx. There is development of vesicle on skin. In some cases, they occur usually on the palms of hands and soles of feet.

Intraorally it can occur at any site, but lips, tongue, palate and oropharynx appear to be affected. These lesions being as small vesicles which rapidly rupture, but heal within two weeks.

Condyloma Acuminatum

It is also called as ‘genital wart’, ‘venereal wart’ or ‘verruca acuminata’. It is caused by human papillomavirus (HPV). It can be transmitted from mother to infant, at birth and resulting syndrome is called as *juvenile onset respiratory papillomatosis*.

Clinical Features

- *Incubation period*—it is about 1 to 3 months from the time of sexual contact.
- *Locations*—it is seen on external genitals, perianal mucosae, and adjacent skin as well as in vaginal and anal canal. Wart growth is favored by moist warm environment of perianal skin and mucosal surface.
- *Appearance*—they are a pink, fleshy papillomatous lesion which proliferate and coalesce rapidly to form diffuse papillomatous clusters of varying sizes.

Oral Manifestations

- *Sites*—it may involve gingiva, cheek, lip, hard palate, tongue and floor of mouth.
- *Appearance*—small keratotic warts occurring alone or in clusters on oral mucosa can be seen.
- *Size*—the enlargement may be larger than 1 cm in diameter.
- *Margins and base*—the lesion is sharply delineated and may appear sessile and pedunculated.

Diagnosis

- *Clinical diagnosis*—sessile pink pedunculated growth with history of oral sex is important in clinical diagnosis.
- *Laboratory diagnosis*—virus isolation can be done by staining of viral antigen DNA by hybridization restriction, endonuclease analysis and polymerase chain reaction.

Differential Diagnosis

- *Focal epithelial hyperplasia*—in it, fine granular surface texture and plaque-like shape of enlargement while in case of condyloma, there is cauliflower appearance.

Management

- *Surgical*—genital warts are treated by excision, electro- or cryosurgery, CO₂ laser therapy.
- *Application of chemical agents*—application of chemical agents such as podophyllin, cantharidin and 5-fluorouracil can be given.
- *Immunomodulating agents*—immunomodulating agent such as interferon can also be used in case of condyloma acuminatum.

Verruca Vulgaris (Common Wart)

Verruca vulgaris is caused by HPV virus type 2,4,6 and 40. It is transmitted by autoinoculation and develops on other part of the body and skin.

Clinical Features

- *Age*—it is common in children and some cases may be found in middle age.
- *Site*—skin of hand is common site and in case of oral cavity it is commonly present a vermilion border, labial mucosa and anterior tongue.
- *Appearance*—it appear as papular or nodular growth with papillary projection. The color of cutaneous lesion is pink, yellow, or white and oral lesions are usually white in color (**Fig. 31-24**).
- *Surface of lesion*—rough and pebbly.
- *Base*—base is pedunculated or sessile.
- *Keratin horn or cutaneous horn*—in some cases, extreme accumulation of keratin will result in hard surface projection. This is called as cutaneous horn or keratin horn.

Fig. 31-24: Common wart seen on finger (Courtesy Dr Pincha).

Diagnosis

- *Clinical diagnosis*—keratin horn with pedunculated surface pebbly lesion on hand will diagnose this condition.
- *Laboratory diagnosis*—there is proliferation of hyperkeratotic stratified squamous epithelium which are arranged in finger-like projection. There is also cupping effect.

Management

- *Cryotherapy*—liquid nitrogen cryotherapy is the treatment of choice in this condition. Cryotherapy will induce subepithelial blister which lifts the infected epithelium from the connective tissue allowing it to slough away.

- *Surgical excision*—surgical excision is usually carried out in case of oral lesion.
- *Keratinolytic agents*—topical application of keratinolytic agents can also be done.

Molluscum Contagiosum Infection

It is caused by molluscum contagiosum virus pox group.

Transmission

- *Skin contact*—it occurs due to intimate skin contact.
- *Sexual contact*—there is marked increase at the time of onset of sexual activity.
- *Predisposing factors*—poverty, overcrowding and poor hygiene are predisposing factors for transmission of virus.

Clinical Features

- *Incubation period*—incubation period is 14 to 50 days.
- *Age*—it is more common in children and young adults.
- *Sites*—it is more common on skin of inner thigh, lower abdomen or external genitals. Some cases may be seen on lips, tongue and buccal mucosa.
- *Appearance*—it manifests as multiple or isolated discrete elevated nodules, or sometimes papules, with depressed centers, which may be keratinized and are normal or pink in color.
- *Adjacent area*—adjacent area is surrounded by the zone of erythema.
- *Shape and size*—these lesions are hemisphere in shape, usually about 5 mm in diameter.
- *Number*—multiple lesions sometimes numbering 100 can also occur.
- *Healing*—it is self limiting and regresses spontaneously within 1 to 2 months.

Diagnosis

- *Clinical diagnosis*—discrete nodule with depressed center is typical of this disease.
- *Laboratory diagnosis*—it shows large eosinophilic intracytoplasmic inclusion bodies known as Henderson-Paterson inclusion or simply Molluscum bodies, measuring approximately 25 microns in diameter in the biopsy.

Management

- *Surgical therapy*—it includes curettage, followed by local cautery, cryotherapy.
- *Topical therapy*—topical application of caustic acid and irritants such as phenol, TCA, podophyllin and cantharidin.

Epstein-Barr Virus (EBV) Infection

The prevalence of EBV antibodies increase in adolescence and early adulthood due to increased opportunity for exchange of EBV in saliva, associated with adolescent, social activity. In this group, it is often characterized by a syndrome referred as infectious mononucleosis or '*kissing's disease*'. EBV may occur as blood borne infection.

EBV is associated with:

- Infectious mononucleosis (discussed in Chapter 37: Blood Disorders)
- Anaplastic nasopharyngeal carcinoma
- Burkitt's lymphoma (discussed in Chapter 37: Blood Disorders)
- B cell lymphoma (discussed in Chapter 37: Blood Disorders)
- Hairy leukoplakia (discussed in Chapter 35: AIDS).

Smallpox

It is also called as '*variola*'. On December 9, 1979, the WHO global commission for the certification of smallpox declared that smallpox eradication has been achieved throughout the world. Thus, there has been for the first time in history that a disease was totally eliminated from this planet.

Previously this disease manifested as occurrence of high fever, nausea, vomiting, chills and headache. The patient is extremely ill and may become comatose during this period. Orally there is ulceration of oral mucosa and pharynx is common. Multiple vesicles appear and rupture to form ulcers of non-specific nature.

Immunization is essential in the early period of life.

Chikungunya

Chikungunya is a relatively rare form of viral fever caused by an alpha virus that is spread by mosquito bites from the *Aedes Aegypti* mosquito, though recent search by the Pasteur Institute in Paris claims the virus has suffered a mutation that enables it to be transmitted by *Aedes Albopictus* (Tiger mosquito). Chikungunya is closely related to O'nyong'nyong virus.

The disease was first described by Marion Robinson and W.H.R. Lumsden in 1955, following an outbreak on the Makonde Plateau, along the border between Tanganyika and Mozambique, in 1952.

Chikungunya is not considered to be fatal. However, in 2005-2006, 200 deaths have been associated with this disease on Reunion Island and a widespread outbreak in southern India. Tamilnadu reported the largest no. of cases as of July 2006, specifically in Madurai and Tirunelveli.

Clinical Features

- **Symptoms**—it includes fever which can reach 39 degree Celsius. Fever lasts for 2 days and comes down. There is petechial or maculopapular rash usually involving the limbs and trunk, and arthralgia or arthritis affecting multiple joints which can be debilitating.
- **Other symptoms**—there can also be headache, conjunctival infection and slight photophobia.
- **Persistent symptoms**—however, joints pain, intense headache, insomnia and extreme degree of prostration lasts for about 5-7 days.
- **Dermatological manifestation**—it includes maculopapular rash, nasal blotchy erythema, lymphoedema over acral area, multiple ecchymotic spots, vesiculobullous lesions, sublingual hemorrhage, photo urticaria and acral urticaria
- **Oral manifestation**—lichenoid eruptions, aphthous ulcers (**Fig. 31-25**), freckle pigmentation over facial area.

Fig. 31-25: Aphthous type ulceration seen in Chikungunya patient.

Management

- There is not any treatment available for this disease. Only symptomatic treatment in the form of analgesics can be given.

Introduction

Nowadays as patient is receiving broad spectrum antibiotics, radiation, cytotoxic and immunosuppressive drugs, there is increases incidence of fungal disease in the society. Many of the fungal disease are not diagnosed due to lack of diagnostic facility. Fungi belongs to plant kingdom which are non-photosynthetic due to absence of chlorophyll. Pathogenic fungi exists in three forms like yeasts, yeast like and filamentous organism.

Infection Caused by Fungi

The spectrum of infection cause by fungi is wide and there is no satisfactory classification of fungal disease. Some important dental point of view fungal disease are described below.

Histoplasmosis

It is also called as 'Darling's disease'. It is caused by *Histoplasma capsulatum*, a dimorphic fungus that grows in the yeast form in infected tissue. Infection results from inhalation of dust contaminated with dropping, particularly from infected birds.

Types

- Acute primary histoplasmosis
- Progressive disseminated histoplasmosis
- Chronic cavitory histoplasmosis.

Clinical Features

- *Acute primary histoplasmosis*—primary infection is mild, manifesting as self limited pulmonary disease that heals to leave fibrosis and calcification. There is chronic low grade fever, malaise, headache and productive cough. There may be pleuritic pain. Chest radiograph may

show patchy infiltrate which may exhibit signs of calcification.

- *Progressive disseminated histoplasmosis*—it is seen in children and elders. It is manifested in hepatosplenomegaly and lymphadenopathy. Patients with disseminated form show evidence of bone marrow involvement by anemia and leukopenia. There is also kidney involvement with gastrointestinal and oropharyngeal ulcerative lesions.
- *Chronic cavitory histoplasmosis*—it closely mimics chronic cavitory tuberculosis. The cavitory lesions are bilateral and are found in the upper lung fields. Symptoms include cough, dyspnea and weight loss.
- *Laboratory diagnosis*—the organisms are found in large numbers in phagocytic cells and appear as tiny intracellular structures measuring little more than 1 micron in diameter. Biopsy shows small oval yeasts within macrophages and reticuloendothelial cells as well as chronic granuloma, epithelial cells, giant cell with caseation necrosis.

Oral Manifestations

- *Sites*—it is seen on buccal mucosa, gingiva, tongue, palate or lip. Oral lesions are common in the progressive disseminated form.
- *Symptoms*—patient may complain of sore throat, painful chewing, hoarseness, difficulty in swallowing.
- *Appearance*—oral lesions are nodular, ulcerative or vegetative. If left untreated, it will progress to form firm papule or nodules which ulcerate and slowly enlarge. It resembles malignancy.
- *Base and surface*—ulcerated area covered by nonspecific gray membrane (**Fig. 32-1**) and is indurated.

Diagnosis

- *Clinical diagnosis*—hepatomegaly, splenomegaly, with oral ulcerative lesion will give clue to the diagnosis.

Fig. 32-1: Ulcerative lesion seen in female patient in histoplasmosis. It is mistaken as malignancy of mandibular vestibule.

- **Laboratory diagnosis**—Histoplasma organisms are found in phagocytic cells.

Differential Diagnosis

- **Tuberculosis**—sputum examination, tuberculin test.
- **Blastomycosis**—biopsy and culturing the organism from tissue.
- **Mucormycosis**—biopsy.
- **Cryptococcosis**—organisms cultured on Sabouraud's glucose agar.

Management

- **Supportive treatment**—patient should be given analgesic and antipyretics to control pain and fever.
- **Ketoconazole**—it should be given for 6 months in non-immunosuppressed patient.
- **Itraconazole**—this agent is more effective and less toxic than ketoconazole.
- **Amphotericin B**—intravenous amphotericin B should be given in chronic and severe form.

African Histoplasmosis

It is caused by fungus *Histoplasma duboisii* that is larger than *Histoplasma capsulatum*. The disease, because of its clinically distinct form and geographical distribution is called as African histoplasmosis.

The disease exists in two forms, i.e. localized and disseminated.

Clinical Features

- **Localized form**—it is confined to the skin, lymph nodes or localized bony areas. Bones when involved, may show cyst-like lesions.

- **Disseminated form**—in disseminated form, multiple cutaneous lesions and involvement of viscera, especially liver and spleen occurs. The course of disease is progressive and fatal.

Oral Manifestation

- **Site**—it involves mucosa and jaw bones.
- **Signs**—mandibular and maxillary involvement is usually presented as bony resorption, resulting in loosening of teeth.

Diagnosis

- **Clinical diagnosis**—multiple cutaneous lesion with loosening of teeth may give clue to diagnosis.

Management

- **Amphotericin B**—amphotericin B is the drug of choice and lesion may require surgical intervention.

Blastomycosis

It is caused by '*blastomyces dermatitidis*'. Organism is a normal inhabitant of soil and that is the reason for it to be common in agricultural worker. It is transmitted through the respiratory tract. Infection with blastomycosis begins in a vast majority of cases by inhalation. Oral lesion may be primary (local inoculation) or secondary (extrapulmonary dissemination) to some infection elsewhere in the body.

Types

- Primary pulmonary blastomycosis
- Cutaneous blastomycosis
- Disseminated or systemic blastomycosis.

Clinical Features

Primary pulmonary blastomycosis

- **Age and sex**—it is more common in men than women and typically occurs in middle age.
- **Symptoms**—it follows a chronic course with malaise, high grade fever and mild cough. If untreated, shortness of breath, weight loss and blood tinged sputum are encountered. In some cases, it may precipitate adult respiratory distress syndrome.

Cutaneous Blastomycosis

- **Sites**—infection of skin, mucosa and bone may also occur, resulting from metastatic spread of organism through lymphatic system.
- **Appearance**—skin and mucosal lesion starts as subcutaneous nodule and progresses to well circumscribed indurated ulcer.

- **Signs**—elevated, verrucous, crusted and single or multiple lesions developing on exposed part of the body, particularly on hands and face.
- **Margins**—lesion leaves a slanted serpiginous border with a tendency towards healing in the center. When the crust is lifted, pus exudes.

Disseminated or Systemic Blastomycosis

- **Cause**—it results from the spread of infection from pulmonary form.
- **Sites**—bones are involved in larger number of cases. Liver, kidney, spleen and gastrointestinal tract may be involved.
- **Signs**—cerebral abscess are found, which occur as a result of brain involvement.

Oral Manifestations

- **Symptoms**—oropharyngeal pain is present.
- **Signs**—enlargement of cervical lymph nodes occurs.
- **Appearance**—non-specific, painless verrucous ulcer with indurated borders is present. It is often mistaken for squamous cell carcinoma (**Fig. 32-2**). Some lesions are hard nodules and appear as sessile, granulomatous appearing plaque.

Fig. 32-2: Blastomycosis presenting as ulcerative lesion resembling squamous cell carcinoma.

Radiographic Features

- **Periosteal reaction**—radiograph may show periostitis and sub-periosteal new bone formation. Osteoblastic reaction is usually present in the later stages of disease.
- **Chest radiograph**—chest radiograph show concomitant pulmonary involvement in most of the cases.

Diagnosis

- **Clinical diagnosis**—the index of suspicion is increased when chronic, painless, oral ulcer appears in an agri-

cultural worker or when review of system reveals pulmonary symptom.

- **Radiological features**—chest radiograph will show pulmonary involvement.
- **Laboratory diagnosis**—diagnosis is made on the basis of biopsy and on culturing the organism from tissue.

Differential Diagnosis

- **Squamous cell carcinoma**—present for weeks or months, palpation shows induration, most common in older patient.
- **Tuberculosis**—undermined flabby borders, usually painless, sputum examination, Mantoux test.
- **Histoplasmosis**—culture and biopsy should be done.
- **Mucormycosis**—biopsy.
- **Cryptococcosis**—organism culture should be done.

Management

- **Itraconazole**—it is generally recommended for the patient of chronic blastomycosis.
- **Amphotericin B**—it is usually given in chronic case of blastomycosis. Intravenous amphotericin B for 8 to 10 weeks causes resolution of the disease. In case of acute blastomycosis, it does not require any treatment.

Mucormycosis

It is also called as '*phycomycosis, zygomycosis*'. It is caused by saprobic organism of class Zygomycetes. It is more common in patients with decreased resistance, due to diseases like diabetes, tuberculosis, renal failure, leukemia, cirrhosis and in severe burn cases. It begins with inhalation of fungus by susceptible individual.

Types

- **Superficial**—it involves external ear, fingernails and skin.
- **Visceral**
 - **Pulmonary**
 - **Gastrointestinal**
 - **Rhinocerebral or rhinomaxillary form**—it is important with dental point of view.

Clinical Features

- **Locations**—infection usually arise in lateral wall of nose and maxillary sinus; may rapidly spread by arterial invasion to involve the orbit, palate, maxillary alveolus and ultimately the cavernous sinus and brain through hematogenous spread and may cause death.
- **Symptoms**—ptosis, proptosis, nasal obstruction, fever, swelling of cheek and paresthesia of face can occur.

- *Intracranial involvement*—intracranial involvement may be heralded by cranial neuropathy, especially of the trigeminal and facial nerve. There is increased lethargy, progressive neurologic deficit and ultimately death.
- *Artery involvement*—fungus invades artery to cause fibrosis and ischemia of the supplied area.
- *Nose*—there is appearance of a reddish black nasal turbinate and septum. Nasal discharge caused by necrosis of nasal turbinate.

Oral Manifestations

- *Site*—most common site involved is maxillary sinus. Other sites which can also be involved are palate, lip, alveolar bone and gingiva.
- *Signs*—ulceration of palate may occur due to necrosis and invasion of palatal vessels. It is large and deep, causing denudation of underlying bone (**Fig. 32-3**). Ulcer may be seen on gingiva, lip and alveolar bone. Ulcer on palate may appear black and necrotic.
- *Massive destruction*—it can be seen when the condition is not treated at the earliest.

Fig. 32-3: Mucormycosis showing deep ulceration of the palate (Courtesy Dr Ashok L).

Radiographic Features

- *Appearance*—paranasal sinus may reveal mucoperiosteal thickening of the involved sinus. With disease progression, there is increased nodularity and soft tissue thickening, usually mimics a tumor on radiographical examination.
- *CT scan features*—CT scan is most helpful for detecting the degree of bone destruction and for evaluating disease extension into the orbit and brain (**Fig. 32-4**).

Diagnosis

- *Clinical diagnosis*—the nose involvement with destruction of palate, neurological finding may give clue to the diagnosis.

Fig. 32-4: CT scan showing increased radiopacity due to soft tissue mass in left maxillary sinus (Courtesy Dr Iswar).

- *Radiological finding*—CT scan will help in the diagnosis.
- *Laboratory diagnosis*—organism appear as nonseptate hyphae with branching at obtuse angles.

Differential Diagnosis

- *Squamous cell carcinoma*—indurated, longer history, resistance to therapy, firm borders, older patient, biopsy.
- *Necrotizing sialometaplasia*—rare, limited to hard and soft palate, usually painless.
- *Aphthous ulcer*—short duration, painful, heals in one to three weeks.

Management

- *Surgical debridement*—radical surgical debridement of infected and necrotic tissue should be carried out.
- *Amphotericin B*—systemic administration of high dose of amphotericin B should be given.
- *Control of underlying disease*—control of predisposing factors such as diabetes should be attempted.
- *Obturation*—prosthetic obturation of palatal defect should be carried out.
- *Symptomatic treatment*—it should be given to eliminate secondary infections and pain relief.

Cryptococcosis

It is also called as 'torulosis'. It is a chronic fungal infection caused by *Cryptococcus neoformans* and *Cryptococcus bacillispora*. The causative organism is gram positive, budding, yeast-like cell with an extremely thick, gelatinous capsule, measuring 5 to 20 microns in diameter. Infection

occurs due to inhalation of airborne microorganism. It has increased incidence in immunosuppressive patients, most commonly in HIV positive patient.

Clinical Features

- *Age*—there is slight predilection for middle aged males.
- *Site*—the infection usually occurs in lungs.
- *Symptoms*—it may be asymptomatic and in some cases, patient may complain of cough with mucoid expectoration. Occasionally, pleuritic pain and hemoptysis can also occur.
- *Skin lesion*—the skin lesion appears as multiple brown papules which ultimately ulcerate, the clinical picture is nonspecific.
- *Neurological features*—meningoencephalic lesions produce a variety of neurologic signs and symptoms, generally associated with increased intracranial pressure.
- *Coin lesion*—the radiograph of chest shows infiltrates and occasionally 'coin' lesion.
- *Diagnosis*—the organisms can be cultured on Sabouraud's glucose agar.

Oral Manifestations

- *Locations*—lesion of hard palate, soft palate, gingiva, extraction socket, tongue and tonsillar pillar are common.
- *Appearance*—they appear as simple non-specific, single or multiple ulcers. They are nodular and granulomatous, which may ulcerate during the course of disease.

Diagnosis

- *Clinical diagnosis*—the brown skin lesion with neurological features and non-specific ulcer seen in oral cavity.
- *Laboratory diagnosis*—gram positive yeast-like cell with gelatinous capsule.

Management

- *Ketoconazole*—mild to moderate cases can be treated with ketoconazole for 6 to 12 weeks.
- *Amphotericin B*—the severe form requires amphotericin-B, intravenously for up to 10 weeks.
- *Combination therapy*—combination therapy of amphotericin B and flucytosine is used in many cases to treat the disease. Another combination of fluconazole and itraconazole is also useful in Cryptococcosis infection.

Coccidioidomycosis

It is also called as 'valley fever', 'desert fever' or 'coccidioidal granuloma'. The disease appears to be transmitted to man and animals by inhalation of dust contaminated by the

spores of the causative organism, *Coccidioides immitis*. Symptoms occur usually 14 days after the inhalation of fungus. Infection is common in summer months, especially after periods of dust storm. It is self limiting and runs its course within 10 to 14 days. Lesions of head and neck, including the oral cavity, occur with some frequency.

Types

- Primary non-disseminated coccidioidomycosis.
- Progressive disseminated coccidioidomycosis.

Clinical Features

- *Age and sex*—it is common in all age groups and predominantly seen in males.
- *Primary pulmonary coccidioidomycosis*—the patient generally develops manifestations suggestive of respiratory disease such as cough, pleural pain, headache and anorexia. Patient may also complain of low grade fever and joint pain.
- *Primary cutaneous coccidioidomycosis*—skin lesions are also present, like erythema nodosum or erythema multiforme. Primary lesions, when they occur, are associated with regional lymphadenopathy. Granulomatous, verrucous or necrotic ulcers exuding thick pus are seen on involved skin surface.
- *Progressive disseminated coccidioidomycosis*—the disease usually runs rapid course and the dissemination extends from the lungs to various viscera, bones, joints, skin and central nervous system, where meningitis is the most frequent cause of death.

Oral Manifestations

- *Appearance*—the lesions of oral mucosa and skin are proliferative, granulomatous and ulcerated lesions that are non-specific in their clinical appearance.
- *Healing*—these lesions tend to heal by hyalinization and scar formation.
- *Lytic lesion*—lytic lesions of jaw may develop.

Diagnosis

- *Clinical diagnosis*—symptoms suggestive of respiratory disease, granulomatous and ulcerated oral lesion may give clue to the diagnosis.
- *Laboratory diagnosis*—biopsy shows mononuclear cell, lymphocytes, and plasma cells with foci of coagulation necrosis.

Management

- *Amphotericin B*—it has been found to be an effective chemotherapeutic agent for the disease. It is given in

patient who is immunosuppressive, disseminated infection and severe pulmonary infection. Long term therapy is required for complete cure.

- *Fluconazole*—it is given in high doses for extended period of time.
- *Ketoconazole*—it is used as an alternative therapy to amphotericin B.

Paracoccidioidomycosis

It is also called as 'South American blastomycosis', 'Lutz disease'. It is caused by *Paracoccidioides brasiliensis*. It is more commonly seen in farmers.

Clinical Features

- *Geographic location*—this is more commonly seen in South America.
- *Age and sex distribution*—it is exclusively found in males as compared to females. It is more common in middle age group.
- *Signs*—patient usually present with signs of pulmonary infection. In some cases, adrenal involvement also occur resulting in hypoadrenocorticism.

Oral Manifestation

- *Site*—commonly affected site are alveolar mucosa, gingiva, and palate. Lips can also be affected.
- *Appearance*—oral lesion appear as mulberry-like ulceration.

Diagnosis

- *Clinical diagnosis*—signs of pulmonary infection, with mulberry-like ulceration.
- *Laboratory diagnosis*—size of this organism is larger than North American form.

Management

- *Sulfonamide*—this can be used to treat mild to moderate infection.
- *Amphotericin B*—this is used in severe cases. It should be used intravenously.
- *Itraconazole and ketoconazole*—this can also be used in some cases when the condition is not life threatening.

Geotrichosis

It is caused by organism *Geotrichum candidum*. It is found in patients with debilitating diseases.

Clinical Features

- *Location*—these are more commonly found in lungs and oral mucosa.

- *Symptoms*—lung involvement produce symptoms of pneumonitis or bronchitis. The expectoration is often tinted with blood.

Oral Manifestations

- *Appearance*—they are similar to candidiasis or thrush (Fig. 32-5), being white, velvety, patch like covering of the oral mucosa, isolated or diffuse in distribution.
- *Tonsillar lesion*—tonsillar lesions are common in association with oral lesions.

Fig. 32-5: Geotrichosis presenting as candidiasis type lesion on oral cavity.

Diagnosis

- *Clinical diagnosis*—lung involvement with candidal type lesion in debilitated patient.
- *Laboratory diagnosis*—the organism is small, rectangular shaped; spores measuring approximately 4 to 8 microns, often with rounded ends. The tissue reaction is non-specific and of acute inflammatory type.

Management

- *Antifungal therapy*—it includes topical and systemic application of nystatin and amphotericin B.

Sporotrichosis

It is a fungal infection caused by *Sporotrichum schenckii*. The disease predominantly affects skin.

Causes

- *Exposure to animal*—exposure to a wide variety of animals, both domestic and wild.

- *Accidental injury*—accidental injury from the thorns of some plants or bushes. Accidental laboratory or clinical inoculation in hospital workers.

Clinical Features

- *Incubation period*—the incubation period is from a week to 3 weeks. It involves the skin, subcutaneous tissues and oral, nasal and pharyngeal mucosa.
- *Skin lesion*—the skin lesion often described as sporotrichotic 'chancre' appears at the site of inoculation as firm, red to purple nodule which soon ulcerates.
- *Lymph nodes*—regional lymphadenopathy is generally developed and it may ulcerate and drain.

Oral Manifestations

- *Location*—non-specific ulceration of the oral, nasal and pharyngeal mucosa.
- *Appearance*—long standing lesions become granulomatous, vegetative or papillomatous.
- *Symptoms*—pain is present and the cervical lymph nodes are always enlarged.

Radiographic Features

- *Incidence*—it rarely involves the bone, it resembles to those which occur in tuberculosis.
- *Appearance*—in the mandible, there is large destructive lesion in the molar region and ramus. It has a loculated cystic appearance, which causes marked expansion of the inferior aspect of the jaw.
- *Periosteal reaction*—in long bones, sporotrichosis may produce some periosteal new bone, but this reaction is confined to jaws of children.

Diagnosis

- *Clinical diagnosis*—lymph nodes enlargement with non specific ulceration of oral cavity will give clue to the diagnosis.
- *Radiological diagnosis*—periosteal reaction with expansion of inferior portion of jaw.
- *Laboratory diagnosis*—the fungus is small, ovoid branching organism with septate hyphae showing budding form. It is only 3 to 5 microns in diameter and can be cultured on Sabouraud's glucose agar medium. The tissue reaction is a granulomatous.

Management

- *Potassium iodide*—it includes oral administration of potassium iodide in suitable doses.

Rhinosporidiosis

It is caused by *Rhinosporidium seeberi*. It affects oropharynx and nasopharynx.

Clinical Features

- *Location*—it is more common on oropharynx, nasopharynx, larynx, skin, eyes and genital mucosa.
- *Symptoms*—initial symptoms include nasal irritation, accompanied by mucoid discharge.
- *Skin lesion*—the skin lesion appears as small verrucae or warts, which ultimately become pedunculated.
- *Signs*—posteriorly, these polypoid masses may extend into the pharynx. The lesions are soft, friable and highly vascular.
- *Genital lesions*—genital lesion resembles condyolomas.

Oral Manifestations

- *Sites*—the soft palate appears to be the most frequent site of oral involvement.
- *Appearance*—it is accompanied by a mucoid discharge and appears as soft, reddish pink, polypoid growth of tumor like nature which spreads to the pharynx and larynx. The lesions are vascular and bleed readily.

Diagnosis

- *Clinical diagnosis*—pedunculated wart with nasal polypoid mass, with intraoral soft reddish pink growth on soft palate.
- *Laboratory diagnosis*—the organisms appear as sporangia containing large number of round or ovoid endospores with size of 5 to 7 microns in diameter.

Management

- *Surgical*—surgical removal of the growths and application of cautery is the treatment recommended for rhinosporidiosis.

Aspergillosis

It is a fungal infection caused either by sensitization to parasitic colonization, or tissue invasion by species of genus *Aspergillus*. It is second to candidiasis, as an opportunistic infection, in immunocompromised patients. It is more commonly seen in diabetes mellitus patients.

Clinical Features

- *Sites*—the respiratory tract, external auditory canal, nasopharynx, cornea, gastrointestinal tract and occasionally the skin may be the primary sites of infection.

- *Symptoms*—in some cases, there may be asthmatic episode in sensitive persons.
- *Nasal aspergillosis*—it may present swelling, ulceration, crusting and necrosis of anterior turbinates, nasal septum and nasal wall.
- *Allergic fungal sinusitis*—in some cases, disease may appear as allergic infection appearing in the sinus.
- *Aspergilloma*—it is mass of fungal hyphae seen in maxillary sinus.
- *Disseminated form*—this type of aspergillosis infection occur in case of immuno-compromised patient. Patient may have chest pain, cough and fever in this case. Prognosis of the patient is poor in this case.

Oral Manifestation

- *Sites*—it is seen on palate and tongue. Soft palate involvement seems to be more common in upper respiratory tract involvement.
- *Palatal lesion*—a lesion on the palate is manifested as a painful ulcer, surrounded by a ring of black necrotic tissue.
- *Gingival ulceration*—this is also a common feature of aspergillosis infection in oral cavity. The color of ulceration may be gray or violaceous hue.
- *Antroliths*—this is also reported from patient suffering from aspergillosis.
- *Disseminated infection*—oropharyngeal aspergillosis, in patients with hematological malignancies, presents as yellowish-black ulceration of soft palate and posterior part of tongue. These patients complain of intense local pain, oral bleeding and dysphagia.

Diagnosis

- *Clinical diagnosis*—gray color ulceration in oral cavity accompanied by nasal infection, chest pain may give clue to the diagnosis.
- *Laboratory diagnosis*—organism can be seen on biopsy.

Management

- *Amphotericin B*—it is the treatment of choice. It can be given intravenously.
- *Surgical debridement*—disseminated aspergillosis in immunocompromised patients should be treated on an individual basis surgical debridement.
- *Itraconazole*—itraconazole can be given local debridement of the lesion.

Protozoal Infection

Leishmaniasis

It is caused by the genus *Leishmania* which consist of three flagellate protozoa, which cause variety of distinct infections in man and are transmitted by sandfly bites.

Types

- *Visceral leishmaniasis*—it is also called as *Kalaazar*. It is caused by *Leishmania donovani*.
- *Cutaneous leishmaniasis*—it is caused by *Leishmania braziliensis*.

Clinical Features

Visceral leishmaniasis

- *Incubation period*—incubation period is 2 weeks to 2 years.
- *Symptoms*—onset may be insidious with a low grade fever or it may be abrupt with sweating and high intermittent fever. Cough and diarrhea can also develop.
- *Signs*—the spleen becomes enlarged, often massively. If not treated, patient will become anemic and wasted.

Mucocutaneous leishmaniasis

- *Incubation period*—is 1 week to 1 month.
- *Age*—it is usually seen in young men.
- *History*—there is past history of superficial ulcer of skin, caused by bite of an infected sandfly, which heals with depressed scar.
- *Nose*—nasal mucosa becomes congested and ulcerates. Later, all the soft tissues of nose may be destroyed.

Oral Manifestation

Visceral leishmaniasis

- *Pigmentation of face*—there may be increased pigmentation of face.
- *Gingival finding*—there may be spontaneous bleeding, edematous gingiva and loose teeth.

Mucocutaneous leishmaniasis

- *Incidence*—mucosal lesion usually occurs 1-2 years after skin lesion.
- *Site*—lips, soft palate and larynx may be involved.
- *Appearance*—the mucosal lesions are long standing, destructive, granulating ulcers which in many instance cause severe mutilation of structure involved.
- *Lymph nodes*—regional lymphadenopathy is common.

Diagnosis

- *Clinical diagnosis*—face pigmentation with edematous gingiva will suspect the disease.
- *Laboratory diagnosis*—organisms can be isolated from the lesion.

Management

- *Amphotericin B*—it is the drug of choice for visceral leishmaniasis. If the lesions are multiple, parenteral injection of amphotericin B should be given.

- **Cryosurgery**—in mucocutaneous lesion, small lesion may be treated by freezing with liquid carbon dioxide, curettage or infiltration with 1-2 ml sodium gluconate.

Trichinosis

It is caused by *Trichinella spiralis*, which is small, spiral, thread-like organism. Human infection occurs as a result of eating parasitized food, usually pork, which has not been completely cooked.

Clinical Features

- **Sites**—striated muscle, masseter, neck muscle and diaphragm.
- **Symptoms**—there is fever, facial and periorbital edema, muscle pain and eosinophilia.

Oral Manifestations

- **Site**—tongue is the most common site involved. It also occurs in muscles attached to mandible, in mandibular alveolar process and in gingival tissues.
- **Symptoms**—there is trismus, muscular cramps of the facial muscle, jaw and tongue. There is also monotony of speech.
- **Signs**—there may be petechiae of buccal mucosa, palate and floor of mouth. There is also bleeding from gingiva, lips and nose.

Diagnosis

- **Clinical diagnosis**—trismus, monotonous speech with petechiae of buccal mucosa or palate may give clue to the diagnosis.

Management

There is no specific treatment for trichinosis and in severe cases, prognosis is poor.

Specific System Disorders

Basic Life Support

If the patient is unconscious you have to give him a basic life support. Patient may become unconscious in the dental chair and in that situation; you have to manage the patient in your dental clinics.

When victim heart ceases its activity, respiratory failure and cardiac arrest ensue. In such cases, administration of CPR within 3 minutes of cessation of activity of heart becomes a must.

Basic life support is the attempt to restore lung and heart function. Mainly, you have to follow the ABC of basic life support, i.e. **Airway, Breathing and Circulation**.

Positioning of the Patient

- *Supine position*—patient should be placed in supine position with the brain at the same level as the heart and the feet elevated slightly at 10 to 15 degree angulation. Head down position should be avoided as of gravity will act to force the abdominal viscera superiorly into the diaphragm, thus restricting movements.
- *Position of pregnant women*—if pregnant women loose consciousness in the dental office, the back of dental chair should be lowered to supine position and patient turn towards her right side, with a blanket or pillow under her back on her left to maintain that position.

Airway

Opening the airway and restoration of breathing constitutes the basic steps in life support. Any type of head support on the dental chair should be removed because such support flex the neck and thus making airway maintenance more difficult.

- *Head tilt*—this procedure is accomplished by placing the rescuer's hand on the victim's forehead and applying a firm, backward pressure with the palm.

- *Head tilt chin lift (Figs 33.1 A and B)*—in this, the fingers, of one hand are placed under the body- symphysis region of the mandible to lift the tip of the mandible up, bringing the chin forward. As the tongue is attached to the mandible, it is thereby pulled forward and off from the posterior pharyngeal wall.
- *Head tilt, neck lift*—in this, one hand of the rescuer is placed beneath the victim's neck to lift and support it.
- *Foreign material in airway*—if there is evidence of foreign matter in the airway, then check for airway patency. Partial airway obstruction produces noise and complete airway obstruction produces silence. If foreign body is suspected, the patient must be rolled on one side with lowering its head below the level of heart. Rescuer should place two fingers in the patient's mouth and remove anything in the entire oral cavity.

Breathing

You have to position your cheek close to victim's nose and mouth, look towards victim's chest; then look, listen and feel for breathing (5-10 second) (**Fig. 33-2**). Exhaled air ventilation can be give by mouth to mouth or mouth to nose.

- *Mouth to mouth*—if not breathing, pinch victim's nose close and give 2 full breaths into victim's mouth. This is done by taking a deep inspiration and exhaling in the patient's mouth and then patient is allowed to exhale passively. This procedure is continued at the rate of 12-14/min.
- *Mouth to nose*—when it is impossible to breathe into patient's mouth and if the rescuer if unable to adequately seal the mouth, the above technique is followed. In this technique, the rescuer keeps the head tilted backwards, with one hand on the forehead and other hand lifts victim's mandible, sealing the lips. Taking a deep breath, rescuer seals his lips around the victim's nose and blows in, until he feels and visualize the expansion of victim's lungs.

Figs 33-1A and B: Head tilt chin lift method to maintain the airway of the patient.

Fig. 33-2: Patency of air way should be checked.

- *Postbreathing*—after it, atmospheric air ventilation should be delivered to the victim. If breath does not go in, reposition the head and try again to give breath. If still blocked perform abdominal thrust (Fig. 33-3).

Fig. 33-3: Abdominal thrust should be given to patient if patient is not able to breathe.

Circulation

- *Carotid pulse checking*—you have to check for carotid pulse for 5-10 seconds, at side of victims neck
- *Rescue breathing*—if there is a pulse but victim is not breathing, give rescue breathing at the rate of 1 breath every 5 second or 12 breaths per minute
- *Technique to give compression to chest (Fig. 33-4)*—place heel of one hand on lower part of victim's sternum; with

Fig. 33-4: Technique of describing chest compression.

your other hand directly on tip of first hand, depress sternum 1.5 to 2 inches. Perform 20 compressions to every 4 breaths (rate 80-100 per minute); check for return of pulse every minute. Continue it uninterrupted until advanced life support is available.

Cardiovascular Disease

Symptoms

- *Dyspnea*—it refers to breathlessness on physical exertion.
- *Orthopnea*—it is difficulty in breathing while lying down. It is due to rise in pressure in the right atrium and right ventricle leading to more blood flow into the lungs. Stiffness and congestion of lungs lead to breathlessness.
- *Edema*—edema of the feet and ankles is suggestive of cardiac failure due to retention of salt and water.
- *Pain*—causes of pain in chest are cardiac ischemia and pericarditis.
- *Palpitation*—it refers to awareness of the heart beat. It is a feature of anxious patient, paroxysmal tachycardia and atrial fibrillation.
- *Syncope*—it occurs due to decrease in cardiac output, decreased peripheral resistance or combination of the two.

Signs

- *Anemia*—pallor of skin and mucous membrane
- *Obesity*—such patients are more likely to have cardiac disease.
- *Peripheral cyanosis*—it occurs due to impairment of circulation, as in vasoconstriction, low cardiac output or stress.
- *Central cyanosis*—it occurs due to improper oxygen saturation of blood or due to right to left shunt.
- *Clubbing*—it is seen in congenital heart disease and in advanced cases of infective endocarditis (**Fig. 33-5**).
- *Temperature*—skin may be cold in cardiac failure and syncope.
- *Arterial pulse*—changes in the pulse pattern are noted in arrhythmias, reduced cardiac output, pulmonary embolism and aortic stenosis.

Examination of the Heart

- *Inspection*—enlargement of heart can be seen as a prominence to the left of sternum.
- *Palpation*—apex beat; normally apex beat is palpated within the mid-clavicular line in the 5th intercostal space. Displacement is seen in cardiac enlargement and fibrosis, collapse or removal of lungs.

Fig. 33-5: Clubbing in cardiovascular disease (Courtesy Dr Milind Chandurkar).

- *Dullness*—it is noted in pericardial effusion and emphysema.
- *Auscultation*—it is done to hear the heart sounds and murmurs.
- *First heart sound*—it is heard loudly at the apex. It occurs due to closure of the mitral valve. Accentuation of 1st heart sound is heard in anxiety and thyrotoxicosis, due to tachycardia and in mitral stenosis. Diminished heart sound is heard in myocarditis, cardiomyopathy and mitral regurgitation.
- *Second heart sound*—it is heard due to closure of the aortic and pulmonary valves. Second heart sound is altered in bundle branch block or increased ventricular stroke volume and from left or right shunt.
- *Third heart sound*—it is heard at the apex in young individuals. In older individuals, it is suggestive of mitral regurgitation and cardiomyopathy.
- *Fourth heart sound*—occurs due to forceful left ventricular distension before the first heart sound. It is suggestive of hypertension, cardiomyopathy, ischemic heart disease and left ventricular hypertrophy.
- *Murmur*—it occurs due to turbulent blood flow. It is heard due to abnormal heart valves.
- *Blood pressure*—it increases due to stress or tachycardia.

Consideration of Prophylaxis in Cardiovascular Disease

- *Heart disease in which prophylaxis recommended*—the disease in which prophylaxis recommended are prosthetic cardiac valve including bioprosthetic and homograft valve, previous bacterial endocarditis, surgically constructed systemic pulmonary shunt, rheumatic and other acquired valvular dysfunction, even after valve surgery, cardiomyopathy, mitral valves

prolapse with valvular regurgitation and most congenital heart malformations.

- *Heart disease in which prophylaxis is not recommended*—the disease in which prophylaxis is not recommended are surgical repair without residual symptoms beyond 6 months of atrial septal defect, ventricular septal defect, patent ductus arteriosus, previous coronary arterial bypass graft surgery, mitral valve prolapse without valvular regurgitation, heart murmurs, previous rheumatoid fever without valvular dysfunction and cardiac pacemaker and implanted defibrillation.
- *Dental procedure in which prophylaxis is recommended*—dental procedures likely to induce gingival or mucosal bleeding, including professional cleaning, surgical operations involving respiratory mucosa (including maxillary sinus), incision and drainage of infected tissues and intraligamentary injection.
- *Dental procedure in which prophylaxis is not recommended*—dental procedures not likely to induce gingival bleeding, injection of local anesthesia, shedding of primary teeth and new denture insertion will not require dental prophylaxis.

Angina Pectoris

It is hypoxia of the cardiac muscles, resulting from an imbalance between the oxygen consumption and oxygen supply of the cardiac muscles. It is the name given to paroxysm of pain. If anginal pain persists for more than half an hour, myocardial infarction or some acute abdominal condition should be considered.

Etiology

- *Coronary artery disease*—it is commonly associated with coronary artery disease and coronary artery spasm associated with atherosclerosis.
- *Oxygen carrying capacity of blood*—limited oxygen carrying capacity of blood and excessive oxygen demand.
- *Predisposing factors*—stress, physical or emotional or use of tobacco may predispose to an attack. Stress cause release of catecholamine and tachycardia.

Types

- *Stable*—it occurs with known physical effort and is relieved at rest and on administration of nitrates. It also gets aggravated by cold weather, smoking, emotional upset, high altitude, sexual excitement and straining at stools.
- *Nocturnal*—angina appears in the middle of the night due to left ventricular failure, which may be precipitate by dreams, causing release of catecholamine.

- *Unstable*—this is also called as peri-infarction angina as 20% of these patients develop myocardial infarction within 4 months. The following types of angina are called as unstable angina.
 - Recent angina (less than 60 days).
 - Stable angina in whom symptom are more severe in intensity, frequency and duration.
 - Angina at rest.
 - Angina following myocardial infarction.
- *Prinzmetal's angina*—this occurs in early morning, associated with ST segment elevation on ECG. It responds to nifedipine and nitrates as it is caused by coronary spasm which can be induced by smoking or hyperventilation.
- *Postinfarction angina*—some patients with myocardial infarction develop angina, 2 days to 8 weeks following the infarction.

Clinical Features

- *Age and sex*—it is most common in age range from 45 to 65 years and male to female ratio is 4:1.
- *Symptoms*—there is substernal pain radiating to both arms and ulnar border of the left arm, jaw, teeth, occipital region or epigastrium. The nature of pain is of crushing type. Pain is of short duration, lasting for 3 to 5 minutes. Pressure or discomfort in the substernal region. Patient may feel as if heavy weight has been placed on his chest. There may be breathlessness or fatigue, due to low cardiac output.
- *Relieving of pain after cessation of exertion*—in most of the cases, the pain is relieved by cessation of exertion. For this reason and because of intense pain, the person commonly maintains a fixed position during the attack.
- *Signs*—variation in pulse rate with generalized facial or circumoral pallor with cold perspiration may be exhibited.

Diagnosis

- *Clinical diagnosis*—a typical history of angina itself could give the diagnosis, even in absence of any other abnormalities on investigation or examination. Though physical examination in angina is often normal, certain clues to the presence of IHD may be present like gallop rhythm (third heart sound), left ventricular enlargement, thickened blood vessels and absent pulse, systolic murmur of mitral regurgitation or papillary muscle dysfunction.
- *Diagnostic tests*
 - *ECG*—in 50% of patients resting ECG may be normal.
 - *Stress testing*—with bicycle ergometer using standard protocols, or treadmill.

- *Thallium stress test*—done by injecting thallium, while the patient exercises and then regional myocardial perfusion is assessed by gamma camera.
- *Echocardiography and Doppler study*—this will be helpful to judge the regional wall motion, abnormality and left ventricular thrombus.
- *Coronary angiograms*—to diagnose blockade of coronary arteries and its location and severity.

Prevention of Anginal Attack

- *Modification of life style*—avoid exertion and walking uphill is avoided.
- *Tranquilizer*—diazepam 5-10 mg 6-8 hrly, to relieve anxiety.
- *Coronary vasodilator*—nitrates and calcium antagonist.
- *Control risk factor*—obese patients to reduce weight, smoking strictly forbidden.
- *Antiplatelet drugs*—low dose of aspirin should be given to prevent risk.

Management

- *Nitroglycerine tablet*—if the patient experiences an anginal attack in the dental chair, nitroglycerine tablet or sublingual spray (amyl nitrite) should be immediately applied under the tongue. Dose should be 0.5 mg of glycerine tri-nitrate or 5 mg of isosorbide dinitrate.
- *Prophylactic drugs*—in a known case of angina pectoris relatively short acting antianginal drugs such as sublingual isosorbide dinitrate tablet is recommended prophylactically, before initiating the dental therapy or a particularly stressful phase of dental therapy.

Dental Considerations

- *Difference between anginal pain and pain of dental origin*—the pain is usually referred to jaws and teeth, resembling a toothache and causing patient to seek dental attentions. Due to overlapping of the fifth cranial nerve, cardiac pain may be transmitted to jaws and interpreted as dental pain. Anginal jaw pain is characterized by its severity, its onset associated with exertion and its disappearance with rest. These characters differentiate it from the usual pain of dental origin.
- *Anginal attacks in dental chair*—acute anginal attacks may occur as a result of stress associated with dental services, i.e. extraction. If a patient is known to be angina pectoris patient, short acting antianginal drug such as sublingual isosorbide dinitrate is given prophylactically in addition to any long acting nitrate drugs before initiating dental therapy.
- *Deferring the procedure which require general anesthesia or conscious sedation*—any dental procedure which require general anesthesia or conscious sedation should defer for 3 months duration after recent anginal attacks.

Myocardial Infarction

It results from thrombotic occlusion (or sometimes prolonged spasm) of the infarct related blood vessels. Myocardial ischemia and necrosis occurs from subendocardial to subpericardial region. The entire process takes 6 hours to complete. An anginal attack lasting longer than 30 minutes is considered by definition to be myocardial infarction.

Clinical Features

- *Symptoms*—nausea, vomiting, tachycardia, grossly irregular pulse and breathlessness.
- *Signs*—there is pallor, diaphoresis and pulmonary edema. Initially, there is rise in blood pressure which may be followed by a fall, especially if cardiogenic shock occurs. Heart sounds are muffled. On second and third days, mild fever of 38-39° C may occur.

Diagnosis

- *History*—the characteristic history of chest pain and pain radiating to other areas, as described for angina may be the only guide. Patient who presents the history must be carefully evaluated because in early disease history may be the only positive finding.
- *Clinical symptoms*—clinical symptoms of collapse, severe unremitting chest pain, changes in heart rate, hypotension will give clue to diagnosis.
- *ECG changes*—the electrocardiogram shows changes characteristic of or compatible with acute myocardial infarction in only 80% of the cases and therefore cannot be used, always, to exclude the presence of myocardial infarction. Also shows the earliest change in ST segment elevation with the onset of pain.
- *Nonspecific test*—polymorphonuclear leucocytosis with high ESR may be seen in the first week, due to tissue necrosis.
- *Serum enzymes*—there may be elevation in certain enzymes like CPK, SGOT, LDH and AST in the blood.
- *Radionuclide technique* provides accurate information about myocardial infarction. In these, gammas emitting radionuclide are used in making cardiac scintigrams. Normally, perfuse myocardium is labeled by these radionuclide and abnormally perfuse myocardium is not labeled, producing the cold spot on scintigrams.
- *Positron emission tomography* is also very useful nowadays.

Management

- *Cardiopulmonary resuscitation*—in case of cardiopulmonary arrest, cardiopulmonary resuscitation should be immediately begun.
- *Prophylactic lidocaine*—in patients with life threatening acute arrhythmias, usually premature ventricular

contraction or ventricular tachycardia, occur in the dental office. Before transportation of the patient to an acute care medical facility, prophylactic 10% lidocaine can be injected IM in the deltoid muscle at the dose of 4 to 6 mg/kg body weight.

- Control of chest pain is done by *sublingual nitroglycerine* 0.3-0.4 mg, repeated every 5-10 minutes and morphine hydrochloride 15 mg, subcutaneously.
- *Nitrous oxide* in a concentration of 35%, mixed with oxygen has been quite effective in decreasing the pain of acute myocardial infarction.
- *Anticoagulants* like heparin 2000-5000 units, every 6-8 hourly.
- *Oral aspirin*—oral administration of aspirin daily improves survival but nowadays it is not recommended for daily use.

Dental Consideration

- *Premedication*—these patients require special management because they may have decreased ability to withstand stressful conditions. Patients, for whom dental treatment is particularly stressful, should be premedicated before treatment. Oral benzodiazepam are helpful in 5 mg doses. It should be given in a waiting room 45 minute before the procedure.
- *Patient on anticoagulant therapy*—careful history taking is a must in such patients. Patients on long-term anticoagulant therapy should be given instructions with regard to bleeding, if surgical procedures like dental extraction are carried out. Anticoagulant dosage should be decreased by the cardiologist before any surgery. Sudden withdrawal of anticoagulant drugs may result in thrombosis or embolism.
- *Timing of dental treatment*—after acute myocardial infarction all dental procedure should be deferred for 3 weeks and after that simple emergency dental treatment can be carried out but with the opinion from physician.

Rheumatic Heart Disease and Fever

It is an inflammatory complication that may follow group of streptococcal infection; manifested by one or more of the following arthritis, carditis, and chorea. Rheumatic fever usually comes on 1 to 3 weeks after the streptococcal infection.

Clinical Features

- *Age*—it is usually a disease of childhood occurring most often between the ages of 6 to 16 years with peak of 8 years.
- *Symptoms*—chorea (involuntary movement), the symptoms of acute carditis. The child often complains of sore throat and has a temperature of 38 to 39°C.

- *Signs*—typical subcutaneous nodules may be present. There is involvement of successive joint which are red, tender and painful. Wrist, ankles, elbows and knees are commonly involved (**Figs 33-6A and B**). Murmur and erythema marginatum, epistaxis and abdominal pain.

Figs 33-6A and B: (A) Hand deformity in rheumatoid arthritis (B) same hand in palmar view (Courtesy Dr Milind Chandurkar).

Diagnosis

- *History*—history of preceding streptococcal infection and predominate manifestation of arthritis and carditis.
- *Jones diagnostic criteria*—Jones criteria of diagnosis of rheumatic fever. At least of two major criteria should be followed.

Major criteria	Minor criteria
• Carditis • Polyarthritis • Chorea • Subcutaneous nodule • Erythema marginatum • Characteristic ECG change	• Fever • Arthralgia • Previous rheumatic fever or rheumatic heart disease • Elevated ESR and positive C-reactive protein • Protein raised

Management

- *Rest*—bed rest and sedation during acute episode.
- *Salicylates*—salicylates are almost specific for the pain of rheumatic fever.
- *Prophylaxis*—continued prophylaxis against a beta hemolytic streptococcal infection is indicated and given in the form of a monthly injection of 1.2 million units of benzathine penicillin G or in 200,000 units of oral penicillin, given twice daily or 1 g of sulfadiazine, given orally, once a day. Such prophylactic therapy is discontinued after 20 to 39 years of age.

Dental Considerations

Following are suggestions for prophylactic procedures, for reduction of postextraction bacteremia and the possible development of subacute bacterial endocarditis -

- *History*—proper history taking about evidence of rheumatic fever, MV prolapse. If there is history of rheumatic fever, administer prophylactic antibiotic therapy before dental procedure.
- *Antibacterial mouth rinse*—make the patient rinse with antibacterial mouthwash, such as chlorhexidine immediately before the treatment to help reduce the number of microorganisms.
- *Atraumatic procedure*—keep dental procedure atraumatic as best possible.
- *Refer to physician*—if a febrile illness develops within 3 months of the dental procedure, refer the patient to physician.

Hypertension

Hypertension is the most common and significant medical condition encountered in dental practice. Normal blood pressure is 120/80 mm Hg.

Stages

- *Stage I (mild) hypertension*—a diastolic pressure of 90-99 mm Hg and systolic pressure of 140-160 mm Hg.
- *Stage II (moderate) hypertension*—diastolic pressure of 100 to 109 mm Hg and systolic pressure 160-170 mm Hg.
- *Stage III (severe) hypertension*—it has diastolic pressure 110-119 mm Hg and systolic pressure of 170-190 mm Hg.
- *Stage IV (very severe) hypertension*—it is also called as *malignant hypertension*. It has diastolic pressure more than 120 mm Hg and systolic pressure of 190 mm Hg.

Types

- *Primary or essential or idiopathic hypertension*—it occurs due to hereditary or environmental cause. Environmental cause includes high sodium intake, excessive alcohol consumption, physical inactivity, smoking and stress.

- *Secondary hypertension*—it may be caused by factors such as renal parenchymal disease, renal artery disease, pheochromocytomas, adrenal cortical hyperfunction and central nervous system lesion.

Clinical Features

- *Symptoms*—patient may complaint of occipital headache, dizziness, nausea, vomiting, malaise, and shortness of breath and nose bleed. In some cases chest pain occurs. In a milder form, there is extensive intraoperative bleeding.
- *Signs*—blood pressure above 160 / 100 mm Hg. There is cardiac enlargement and narrowing of retinal arterioles also occurs. Hypertensive patients may lead to hemorrhage, myocardial infarction, cardiac decompression and renal failure.
- *Odontalgia*—odontalgia is observed in hypertensive patients, which occurs due to hyperemia of dental pulp or congestion of this tissue resulting from increase blood pressure.
- *Drug side effect*—many patients in dental office may be reported with gingival enlargement which occurs due to nifedipine (calcium channels blocker) use in hypertensive patients. Antihypertensive medication like thiazides, methyldopa, propranolol, etc. can cause lichenoid reaction in the oral cavity. ACE (angiotensin converting enzyme) inhibitors can cause taste impairment, burning sensation of mouth called as *scalded mouth syndrome*. Xerostomia can also occur due to many antihypertensive drugs.
- *Hypertensive crisis*—hypertensive crisis is a sudden rise of arterial blood pressure to a very high level (160/100 or 250/150 mm Hg) with clinical and pathological manifestations. Such patients can pose problems involving heart, brain and kidney.

Dental Significance

- *Treatment planning*—an elevated blood pressure in a dental patient requires careful consideration in treatment planning, premedication, selection of an anesthetic and determining the duration and extent of operative procedure.
- *Risk of medical emergencies*—undetected hypertension increases the risk of experiencing cardiovascular conditions such as angina, myocardial infarction and cerebrovascular accident while undergoing dental care.
- *Effects of antihypertensive drugs*—oral health care can be affected by the known side effects of antihypertensive drugs and their interaction with other medications.
- *Care of general health*—the dentist can perform a valuable patient service by identifying undetected hypertension.

Dental Management

- *Identification*—the dentist should have equipments in the office to measure blood pressure.
- *Pain control*—effective control of operative and post-operative pain should be done after dental procedure.
- *Stress and anxiety reduction*—elevation of blood pressure caused by nervousness or stressful situations should be minimized in hypertensive patients. The patient should not be permitted to struggle when using inhalation analgesia or general anesthesia and adequate oral and parenteral premedation should be used. Patients with known hypertension should have blood pressure checked at each dental visit, to assure that there is no risk of harm from the stress of dental procedure. Very anxious patient should be given 5 mg of diazepam or 30 mg of oxazepam, night before and one hour before the dental appointment.
- *Limit the use of epinephrine*—epinephrine use should be limited in patient with hypertension. The reason for this many patients of hypertension usually suffer from the cardiovascular disease and epinephrine will cause vasoconstriction in these patients.
- *Avoidance of drug interaction*—many NSAID interacts with ACE inhibitors decreasing the efficacy of antihypertensive agents. Vasopressor drugs can interact with non-selective beta blockers provoking hypertensive episode.
- *Physician referral*—if blood pressure is high, patient should be referred to the physician for further observation and regarding the antihypertensive medication.
- *Emergency extraction*—when extraction is necessary on an emergency basis, the hypertensive patient should be hospitalized and local homeostatic measures should be taken to avoid undue hemorrhage. In these patients, proper premedication should be given.
- *Hypertensive crisis in dental chair*—if it arises intra-operatively, patient should rest in semisitting position. O₂ may be administered; if it does not help, diazepam may be administered at very slow rate. If this is not helpful, the patient should be left to the care of medical physician. In the mean time, injection frusemide is given intravenous and 10 ml capsule of nifedipine may be broken and sprinkled sublingually to bring the blood pressure down.
- *Management of side effects of drugs*—xerostomia should be managed by pilocarpine, sugarless mint or gums and minimizing caffeine intake. Gingival overgrowth is reduced by excellent oral hygiene. Lichenoid reaction is treated by topical corticosteroids.

Infective Bacterial Endocarditis

It is a serious disorder which is the most common bacterial origin but on occasion, it may be mycotic. Causes of

endocarditis of dental origin are almost always caused by bacteria of low virulence, that slowly attack a previously damaged endocardium, causing subacute bacterial endocarditis.

Pathogenesis

- *Organism responsible*—it is usually caused by oral microorganism like alpha hemolytic streptococci, enterococci, pneumococci, staphylococci and group A streptococci.
- *Damaged blood flow*—in normal patients blood becomes sterile after this transient phase. In patients with damaged heart valves, initially there is formation of a sterile platelet fibrin clot or thrombus on the damaged heart surface. It acts as nidus for bacterial proliferation, subsequently leading to infective endocarditis.
- *Oral bacteremia*—dental procedure can lead to release of bacteria into the blood circulation. The most common type of organism responsible for this oral bacteremia is streptococci viridians which are abundantly found in the mouth. It occurs in person who is having poor oral hygiene and undergoing extraction.
- *Consequence of infective endocarditis*—infective endocarditis will lead to proliferation of bacteria on the damaged heart surface can lead to impaired valvular function, congestive heart failure, abscess of myocardium due to production of pus and release of infectious emboli which can get lodged in organs such as brain, kidney and spleen.

Predisposing Factors

- *Heart disease*—it has marked predisposition for persons with rheumatic or congenital, cardiac or vascular defect, bicuspid aortic valve, leutic aortic valvular disease, idiopathic hypertrophic subaortic stenosis and mitral valve prolapse.
- *Surgical correction*—recent surgical correction of congenital valvular defect within 6 months.
- *Hypertrophic cardiomyopathy*—it can also occur in hypertrophic cardiomyopathy.
- *Surgical trauma*—surgical trauma and dental extraction are commonly related chronologically, to the onset of clinical symptoms.

Clinical Features

- *Age*—it can occur at any age, but most common in middle age group.
- *Progress*—after formation of vegetative lesion (thrombi), they serve as foci of the intermittent dissemination of microorganisms throughout the body. These vegetative lesions are friable and small pieces may break off and form septic emboli.

- *Symptoms*—the patients experience progressive weakness, loss of weight, dyspnea, anorexia, muscular and joints aches and pains, with low grade fever.
- *Signs*—Petechial hemorrhage in the conjunctiva and oral mucosa occur due to septic emboli.
- Larger emboli can lodge occasionally in spleen, kidney, lungs and brain where they produce symptoms referable to the structure and the organs involved.

Diagnosis

- *Clinical diagnosis*—it is frequently made by elimination of other conditions. The disease should be suspected in any patient with valvular heart disease, who has unexplained fever for week or more, or exhibits embolic phenomenon or an unexplained anemia.

Management

- *Antibiotics therapy*—intensive antibiotic therapy, usually 20,000,000 units of penicillin in combination with gentamicin for 2 weeks should be given.
- *Removal of infected valve*—early removal of infected valve should be done with sterile replacement.

Dental Considerations

- *Oral cavity, a source of infection*—organisms responsible for subacute bacterial endocarditis were disseminated commonly through bloodstream, following dental extraction. It was demonstrated that gingival sulcus was an important site from which the bacteria gained entrance into the bloodstream. Actual cauterization of gingival crevice before extraction markedly reduces the percentage of transient bacteremia. Even in the absence of direct dental procedure, bacteremia can be produced secondary to foci of infection in the oral cavity.
- *Prophylactic measure*—every known prophylactic measure should be taken to preclude the possibility of transient bacteremia occurring in patients with known vascular lesions.

Prevention

- *Proper history should be taken*—ask the patient about history of rheumatic fever, heart disease with valvular involvement or heart murmur.
- *Prophylactic antibiotics therapy*—if the heart disease to endocarditis is known to be present, administer the prophylactic antibiotic therapy before the dental treatment.
- *Physician consultation*—if questionable positive history of heart disease is obtained, you have to consult the patient's physician. All patients who are at risk of developing endocarditis, subsequent to dental treatment,

should be instructed to consult physician if a febrile illness develops within 3 months of a dental treatment.

- *Antibacterial mouth rinse*—make the patient rinse with an antibacterial mouthwash, immediately before dental treatment, to help reduce the number of oral micro-organisms.
- *Atraumatic dental procedure*—keep dental treatment as atraumatic as possible.

Congestive Cardiac Failure

It is the condition where the heart fails to maintain an output sufficient for the needs of the body.

Classification

- *Low output cardiac failure*—there is a primary lesion in heart which decreases the contractibility of the heart and causes diminished cardiac output.
- *High output cardiac failure*—there is primarily no lesion in the heart, but due to extra cardiac condition, there is increased work load on the heart which causes cardiac failure with increased cardiac output.

Causes

- *Low output failure*—it is caused by myocardial lesions like ischemic heart disease, rheumatoid heart disease, cardiomyopathy, valvular endocarditis, congenital heart disease and vascular lesions like hypertension and aneurysm of aorta.
- *High output failure*—thyrotoxicosis, anemia, hypoproteinemia, beriberi, AV Fistula and cirrhosis of liver can cause congestive cardiac failure.

Clinical Features

- *Symptoms*—there is increased breathlessness following moderate exertion, chronic productive cough associated with blood tinged sputum. Patient also complains of wheezing, anorexia, bronchospasm, and dyspnea.
- *Signs*—pitting edema of lower extremities, hepatic enlargement, and generalized edema. Congestion of the large veins of neck and raised jugular venous pressure. There is also cyanosis of lips, tongue and oral mucosa with ankle edema.

Diagnosis

- *Clinical diagnosis*—breathlessness, generalized edema and raised jugular venous pressure will give clue to diagnosis.

Management

- *Bed rest*—complete bed rest is required.
- *Digoxin*—it should be the first line therapy for heart failure.
- *Diuretic*—in cardiac failure, there is always sodium and water retention, hence diuretics are given.

- *Vasodilators*—vasodilators are given, e.g. nitroprusside—5-10 mg/min.
- *Oxygen*—it can be administered for proper circulation.
- *Massage*—massage of lower limb to maintain peripheral circulation.

Dental Considerations

- *Heart attack in dental office*—the dentist should watch for early signs of congestive cardiac failure like cyanosis of lips, tongue. If the patient develops acute pulmonary edema in the dental office, patient should be made comfortable in sitting position or semisitting position and administered 100% O₂. Injection frusemide and aminophylline should be given. Physician should be immediately called for.

Congenital Heart Disease

Congenital heart diseases are the most common types of anomalies present in child and more common as compared to rheumatic diseases.

Clinical Features

- *Symptoms*—they are variable. Some children manifest breathlessness, inability to thrive, growth retardation and central cyanosis.
- *Persistent ductus arteriosus*—it is failure of closure of ductus arteriosus which plays role in fetal life as most of the blood passes through ductus arteriosus into the aorta. It results in recirculation of blood through the lungs, leading to increased workload on the heart. It occurs commonly in women. Affected individuals may suffer from growth retardation, dyspnea, cyanosis and cardiac failure. Surgical correction is possible in some cases.
- *Atrial septal defect*—it results in shunting of blood from left atrium and then to the right ventricle and pulmonary arteries, leading to progressive enlargement of the right side of the heart and the pulmonary artery with its branches. Females are affected more than males. There is dyspnea, cardiac failure and arrhythmias. It is treated by surgical closure.
- *Ventricular septal defect*—it is usually asymptomatic.
- *Pulmonary stenosis*—it occurs either alone or along with atrial septal defect or ventricular septal defect. Larger pulmonary stenosis results in dyspnea, fatigue or syncope.

Oral Manifestations

- *Bluish red discoloration*—general bluish red discoloration of oral mucosa with severe marginal gingivitis and bleeding.

- *Tongue*—tongue is often deeply fissured and edematous.
- *Delayed eruption*—both permanent and deciduous teeth are delayed in eruption.
- *Enamel hypoplasia*—this is also frequently present in patient with congenital heart disease.
- *Skimmed milk appearance*—teeth will have bluish white skimmed milk appearance with vasodilation in the pulps.

Diagnosis

- *Clinical diagnosis*—generalized bluish discoloration of oral muscle with symptoms of atrial septal defect and persistent ductus arteriosus.

Management

- *Antibiotics prophylaxis*—antibiotics cover is needed for operative procedure.
- *Cardiac surgery*—this should be done to correct congenital anomalies.

Dental Considerations

- *Adequate analgesia*—adequate analgesia should be given to the patient during oral surgical operation. General anesthesia should be avoided.
- *Conscious sedation*—conscious sedation with nitrous oxide should be given with approval of physician.
- *Avoid using gingival retraction cord containing epinephrine*—gingival retraction cord containing epinephrine should be avoided.

Cardiac Transplantation

These patients are on immunotherapy for life. Too little therapy will result in rejection of episode, while too much runs the risk of both infection and neoplasm. Opportunistic infections like fungal, protozoal and viral infection are common in these patients.

Dental treatment after transplantation should be carefully planned in view of the patient's lower immune status with particular attention to WBC count and Hb concentration. Before performing any treatment, the dentist should take consent of the patient's physician and consider antibiotic prophylaxis. As many of these patients are on long-term steroid therapy, steroid supplements should be given.

Prophylactic antibiotic dose and its indications:

- *Amoxicillin*—3 gm orally, 1 hr before the procedure. 1.5 gm 6 hours after the initial dose.
- *Patients with allergy to penicillin*—Erythromycin ethyl succinate 800 mg, Erythromycin stearate 1 gm orally, 2 hours before the procedure. Clindamycin 300 mg 1 hour before the procedure and 150 mg, 6 hours after the initial dose.

Coarctation of Aorta

It is a developmental anomaly characterized by marked diminution in the caliber of aortic arch, just distal to where the left subclavian artery arise.

Patient suffers from secondary hypertension and cerebral aneurysm with hemorrhage.

Intraorally there is marked enlargement of mandibular arteries and branches leading to individual teeth. Arterial hemorrhage will occur following tooth extraction. Pulp of all the four maxillary incisors were markedly enlarged and funnel shaped, occupying great portion of crown and roots.

Respiratory Disorders

Bronchial Asthma

Asthma is a common disease estimated to affect 4 to 5% population. It is initially a spontaneously, reversible, spasmodic contraction of the smooth muscles of bronchi resulting in bronchiolar narrowing. As the attack progresses, resistance to airflow may be further exacerbated by mucosal edema and inflammatory infiltrate of mucosa.

Types

- *Extrinsic asthma*—it is developed by allergic factors. It is also called as allergic asthma. Patient, who is having asthma of allergic origin, often has positive family history of disease and positive atopic history including hay fever, rose fever and eczema.
- *Intrinsic asthma*—it is precipitated by nonallergic factors. It is also called as *non-allergic asthma*, *idiopathic asthma* and *infective asthma*.
- *Mixed asthma*—it is combination of allergic and non-allergic asthma.
- *Status asthmaticus*—it is persistent exacerbation of asthma.

Predisposing Factors

Extrinsic asthma

- *Airborne allergen*—house dust, feathers, animal dander, furniture stuffing, fungal spores and a wide variety of plant pollens.
- *Allergenic food*—it includes cow's milk, eggs, fish, chocolate, shellfish and tomatoes.
- *Allergic drug*—it includes penicillin, vaccines and aspirin.

Intrinsic asthma

- *Infections*—respiratory infections, usually viral, are well known initiating factor in the asthmatic patient.
- *Exercise*—some patients have acute asthmatic attack after prolonged exercise.

- *Psychological*—emotional stress such as nervousness, anxiety can cause asthmatic attack. The dental office is a common site for asthmatic attack. Child may develop asthmatic attack after taken into treatment room and recover after moving out from treatment room.

Clinical Features

- *Age*—it is more common in children, especially boys. It can also occur in older individuals.
- *Symptoms*—patients notice a sensation of fullness in the chest. Predominately, symptoms of acute attack are wheezing, coughing and labored breathing. There is also sneezing and gasping sounds are heard while attempting to breath.
- *Attack termination*—termination of attack is usually heralded by a period of intense coughing with expectoration of thick, tenacious mucous plug which is followed by sensation of relief.
- *Signs*—with severe attack, the patient is extremely anxious and agitated. Heart rate is increased to 130 per minute. Cyanosis of mucous membrane of lips may be visible along with perspiration and flushing of face and upper torso in severe attack. Patient is more comfortable if allowed to sit or stand upright with the back upright and the chest, shoulder and head fixed.
- *Extrinsic asthma*—bronchospasm usually develop within minutes after exposure to allergens. These attacks usually become less frequent and less severe during middle and late adolescence and may disappear entirely.
- *Intrinsic asthma*—attack of intrinsic asthma is usually more fulminant and severe than those of allergic asthma. The long-term prognosis is poorer and the patient eventually exhibits clinical signs and symptoms in interval between acute episodes.
- *Status asthmaticus*—in it, acute asthmatic attack persists in spite of drug therapy. Bronchospasm may continue for hours or even days without remission. Patient more commonly exhibits extreme fatigue, dehydration, severe hypoxia, cyanosis, peripheral vascular shock and drug intoxication from intensive therapy. Chronic partial airway obstruction may lead to death from respiratory acidosis.

Diagnosis

- *Clinical diagnosis*—diagnosis of bronchial asthma is based on the symptoms, pulmonary function test and physical finding of expiratory wheezes during the acute attack.
- *Laboratory diagnosis*—there is raised total IgE and specific IgE antibody concentration.

Management

- *Sympathomimetic amine*—use of drugs like terbutaline, isoproterenol and metaproterenol as first line therapy. It dilates and prevents bronchial smooth muscle constriction.
- *Xanthine derivatives*—xanthine derivatives like aminophylline and theophylline can be used. It inhibits the hydrolytic degradation of cyclic AMP.
- *Corticosteroid*—corticosteroids like hydrocortisone and prednisone can also be used. It lessens intensity of antigen-antibody reaction.
- *Omaliuzumab*—it is recombinant humanized monoclonal anti-IgE antibody, will cause reduction in total serum IgE and thereby decreasing the symptoms of asthma.
- *Sodium cromoglycate*—cromolyn sodium is used. It protects against mast cell destruction.
- *Combination*—inhaled corticosteroids with bronchodilators.
- *Antihistamine*—antihistaminic usually are useful because they produce drying and obstruction of air.
- *Emergency management*—emergency treatment is inhalation of a solution containing 0.1 mg isoproterenol or 1:1000 epinephrines by nebulizer or injection of 0.1 ml of 1:1000 epinephrines. Continuous inhalation by nasal catheter is helpful to relieve the hypoxia.
- *Hydration*—hydration is necessary in the form of 5% glucose in water because there is dyspnea.

Dental Considerations

- *Avoid inhalation anesthetics*—patient using beta-adrenergic inhaler should be reminded to bring the inhaler with them to dental office; the dentist should avoid inhalation anesthetics or analgesic in asthmatic patient because of the possibility of stimulating an acute asthmatic attack.
- *Dental work*—if attacks are seasonal, routine dental work can be performed during the time when frequency of attack is lowest. Patients on steroids may require additional steroid to avoid serious reaction to stress of dental procedure.
- *Attacks in dental chair*—in case of acute attack occurring on dental chair, following measures should be taken:
 - *Terminate the procedure*—terminate the dental therapy and position the patient in any comfortable position.
 - *Administration of bronchodilators*—0.5 ml, 1:1000 adrenelines can be injected subcutaneously or intramuscularly. If attack is prolonged, steroids are indicated
 - *Aerosol spray*—the onset of aerosol drug is rapid and relief of symptoms occurs within seconds.
 - *Administer oxygen*—it may be administered by full face mask, nasalhood or nasal cannula.

Chronic Obstructive Pulmonary Disease

It is characterized by airway obstruction and breathlessness.

Types

- *Chronic bronchitis*—it refers to inflammation of bronchi. It is defined as a condition in which there is mucus producing cough present, for at least 3 months of the year, for more than 2 consecutive years.
- *Emphysema*—it is dilatation of air spaces distal to terminal bronchioles with destruction of alveoli reducing alveolar surface area for respiratory exchange.

Causes

- *Smoking*—the most common cause of COPD is smoking.
- *Environmental dust*—the other factors are chronic recurrent infection, air pollution and occupational inhalants.
- *Deficiency of antiproteolytic enzyme*—deficiency of anti-proteolytic enzyme alpha 1-antitrypsin is a rare cause of emphysema.

Clinical Features

- *Early morning cough*—patient shows early morning mucoid cough which becomes purulent during exacerbation.
- *Pink panter or pink puffer*—this is present in emphysema in hyperventilation, occurs to maintain normal blood gases. This will cause vasodilatation and patient will be pink due to CO₂ retention.
- *Cutaneous vasculitis*—in some cases of emphysema cutaneous vasculitis may be present (**Fig. 33-7**).

Fig. 33-7: Cutaneous vasculitis seen in respiratory disease (Courtesy Dr Milind Chandurkar).

- *Blue bloated appearance*—this is present in chronic bronchitis. In this patient is unable to maintain hyperventilation and become hypoxic. This will lead to central cyanosis, ankle edema, and raised jugular venous pressure of cor pulmonale to give blue bloated appearance. Wheezing, dyspnea and cough.
- *Later stage*—in the later stage, there can be blood tinged sputum and fever.

Diagnosis

- *Clinical diagnosis*—cutaneous vasculitis with pink panter with blue bloated appearance will aid in diagnosis.

Management

- *Stoppage of habit*—patient should ask to quit the habit of smoking.
- *Bronchodilator*—bronchodilators are particularly effective in relieving bronchospasm. Bronchodilators used are ipratropium bromide, oxitropium, and theophylline.
- *Antibiotics*—antibiotic therapy should be initiated with earliest sign of chest infection. Antibiotics used are amoxicillin, trimethoprim, or tetracycline.
- *Oxygen therapy*—oxygen is useful both, intermittently on a chronic basis and continuously with an acute exacerbation of disease.

Dental Considerations

- *Upright position*—patient should be treated in upright position. If patient is flat there are chances of breathlessness.
- *Avoid using rubber dam*—the patient's tolerance to partial airway obstructing devices such as rubber dam is less so use of rubber dam should be avoided.
- *Short treatment time*—mucus producing cough, wheezing, and dyspnea in these patients prevent long treatment sessions. This should be taken into consideration while planning the dental therapy.
- *Inhalation analgesic*—inhalation analgesic should be given only when it is necessary and in conjunction with anesthesiologist.
- *Drug interaction*—as patient is taking theophylline, many drugs like epinephrine, erythromycin, clindamycin, etc. should be given cautiously.
- *Avoid giving general anesthesia*—patient should be avoided giving general anesthesia unless it is very necessary.

Pulmonary Foreign Bodies

Foreign bodies occluding or obstructing a main respiratory passage will produce cyanosis and asphyxia. Sudden and

violent attacks of coughing, accompanied by shortness of breath and chest pain are classic symptoms of pulmonary foreign bodies.

Dental procedures are directly or indirectly involved in a high percentage of foreign body problems hence, the cooperation of the dentist is essential for the prevention of these accidents. Dentures are important indirect cause of foreign body accident. The tactile sense of the denture patient is severely impaired by the dentures and the foreign body (usually bones) may pass the point of recovery by reflex action before the patient becomes aware of it.

Dentures can become embedded in the soft tissue or block the respiratory and alimentary tract, without being detected by the X-ray (as denture material is radiolucent) such as in high velocity automobile accidents.

Denture foreign body can be a portion of tooth, a restoration or an operating instrument that is lost during dental treatment, tooth fragment, instrument during surgery and prosthesis lost by the patient.

The risk of respiratory tract foreign body can be eliminated almost entirely by the use of the rubber dam or throat packs. Complete and partial dentures should be removed during sleep, unconsciousness and before surgery.

Renal Disorder

Renal Failure

Renal failure produces a standard symptom complex, regardless of the underlying cause. It is caused by many diseases.

Etiology

- *Glomerulonephritis*—it represents a heterogeneous group of disease of varying etiologies that produce irreversible impairment of function. The attack of glomerulonephritis is either streptococcal or non-streptococcal. Chronic glomerulonephritis has usually very slowly, but steadily progressive course, leading to renal failure or uremia in few years to as many as 30 years.
- *Pyelonephritis*—it refers to the effect of bacterial infection in kidney, with *E. coli* being the cause of infection. Any obstruction of urinary tract can predispose to active pyelonephritis and also can occur due to generalized sepsis in patients with bacterial endocarditis or with staphylococcal infection. Clinically, there is sudden rise of body temperature, shaking chills, aching pain in one or both costovertebral areas or flanks and symptoms of bladder inflammation.
- *Hemolytic uremic condition*—this condition is caused by *E. coli*.

- *Other diseases*—other diseases which can cause renal failure are polycystic renal disease, nephrosclerosis, diabetic nephropathy, collagen vascular disease, hereditary nephropathy, analgesic abuse nephropathy, obstructive nephropathy, gouty nephropathy, neoplastic nephropathy, etc.

Clinical Features

- *Gastrointestinal*—nausea, vomiting, anorexia, parotitis, gastritis and gastrointestinal bleeding.
- *Neuromuscular*—headache, myoclonic jerks, peripheral neuropathy, paralysis, seizures and asterixis.
- *Hematological and immunological*—normocytic and normochromic anemia, coagulation defects, increased susceptibility to infections, decreased erythropoietin production and lymphocytopenia.
- *Endocrine and metabolic*—renal osteodystrophy, secondary hyperparathyroidism, impaired growth and development, loss of libido and sexual function and amenorrhea.
- *Cardiovascular*—arterial hypertension, congestive heart failure, cardiomyopathy, pericarditis and arrhythmias.
- *Dermatological*—pallor, hyperpigmentation, ecchymosis, uremic frost, pruritus, reddish brown distal nail beds.

Oral Manifestations

- *Incidence*—in the study of renal patients, 90% were found to have oral manifestations.
- *Ammonic taste and smell*—patients complain of *ammonic taste and smell*, particularly in the morning. It is caused by the high concentration of urea in saliva and its breakdown to ammonia.
- *Xerostomia*—the patients may complain of *xerostomia* which is caused by direct involvement of salivary gland, chemical inflammation, dehydration and mouth breathing.
- *Erythromopultaceous form*—the acute rise in BUN level may result in uremic stomatitis, which appears as *erythromopultaceous form*, characterized by red mucosa covered with a thick exudate and a pseudomembrane.
- *Ulcerative form*—in some cases, stomatitis may be in *ulcerative form* which appears as frank ulceration with red and pultaceous coat.
- *Low caries activity*—low caries activity despite of high sugar intake; poor oral hygiene due to increased salivary urea nitrogen.
- *Enamel hypoplasia*—it is frequently seen in patients where renal disease is started at young age.
- *Other*—there is pulpal narrowing and calcification, severe tooth erosion and loss of lamina dura can also be seen.

Diagnosis

- *Clinical diagnosis*—variety of clinical symptoms occur in it with oral manifestation.
- *Radiological diagnosis*—pulpal narrowing with loss of lamina dura can be seen.

Management

- *Hemodialysis*—to remove nitrogenous and toxic products of metabolism from blood by means of a dialysis system.
- *Peritoneal dialysis*—in it, 1-2 liters of dialysate are placed in the peritoneal cavity to remain there for varying intervals of time. Main advantage of this is that there is no risk of air embolism and blood leak.
- *Drug treatment*—Aminoglycoside (gentamicin), antimicrobial (penicillin), analgesic (acetaminophen), narcotic (codeine, morphine), sedative (diazepam), amitryptline, antihistaminic (chlorpheniramine), phenytoin and lidocaine.
- *Kidney transplantation*—it involves surgical removal of a kidney from a donor and implantation into a recipient. This method is for prolonged life in patient with end stage renal failure; the kidney transplantation patient receives a continuous regimen of immunosuppressive medication to ensure graft survival.

Dental Consideration

- Many patients who are receiving dialysis have conditions of oral neglect.
- *Dialysis*—if time and patient's conditions permit, dialysis should be part of the preoperative preparation. Dialysis will return the state of hydration, serum electrolyte, urea nitrogen and creatinine toward normal and will reduce the need for dialysis in the immediate postoperative period.
- *Control of bleeding*—as bleeding is common problems in renal failure patient, hemostasis should be done with the help of desmopressin, cryoprecipitate and conjugated estrogens.
- *Position of patient in dental treatment*—blood flow through the arm should not be impeded by requiring the patient to assume a cramped position or using that arm to measure blood pressure. Patient should avoid sitting for long periods of time with leg dependent. If dental treatment is long, then patient should be allowed to walk for few minutes every hour.
- *Infective endocarditis*—the presence of an access site increases the susceptibility to infective endocarditis. Antibiotic prophylaxis is required for control of infective endocarditis. Start with broad spectrum antibiotic, e.g. amoxicillin 3 g, 1 hr before treatment and 500 mg every 8 hours for 1-2 days.

- *Candidial infection*—candidal infection can occur in oral cavity. For candidiasis, administer nystatin mouthwash 5000000u/ml QID, day before the treatment and 2 days after dental treatment.
- *Medication in dialysis patient*—most drugs are excreted at least partially by the kidney. Following are the drugs to be avoided in dialysis patients:
- *Nonsteroidal anti-inflammatory drugs*—it may induce sodium retention and impair the action of diuretics, prevent aldosterone production and cause acidosis.
- *Tetracycline and steroids*—they are antianabolic and increase urea nitrogen to twice the baseline level.
- *Phenacetin*—it is nephrotoxic and puts added strain on an already damaged kidney.
- *Benzyl penicillin*—this has got significant potassium content and can be neurotoxic. So this drug is contraindicated in renal failure.
- *Others*—other drug which should be contraindicated are absorbed antacids, carbenicillin in large doses, ascorbic acid, ammonium chloride and laxatives.

Renal Osteodystrophy

It occurs due to defect in hydroxylation of 25-HCC to 1, 25-DHCC a process that normally occurs in kidney. Hypocalcemia occurs due to impaired calcium absorption and hyperphosphatemia, due to reduction in renal phosphorous excretion. Hypocalcemia results in secondary hyperparathyroidism with increased level of serum parathyroid hormone. Systemic acidosis is also associated with these conditions. There are symptoms of chronic renal failure.

Clinical Features

- *Myopathy*—muscle cramps are more common; ‘restless leg syndrome’, where patient’s legs jump at night.
- *Neuropathy*—sensory neuropathy may cause paresthesia. Motor neuropathy may present as foot drop. Autonomic neuropathy may cause delayed gastric emptying, diarrhea and postural hypotension.
- *Endocrine function*—there may be hyperparathyroidism and hyperparathyroidism. Amenorrhea is common in females. There is also loss of libido and sexual functions. Growth retardation occurs in children and bone fractures occur frequently.
- *CVS effects*—hypertension results in 80% of patients. This is due to sodium retention and increased secretion of renin, angiotensin-I and aldosterone. Atherosclerosis is common.
- *Acidosis*—there is also acidosis; cellular and humoral immunity are impaired.
- *Bone*—in adults, gradual softening and bowing of bone occurs.

Radiographic Features

- *Radiodensity*—generalized loss of bone density and thinning of bony cortex.
- *Lamina dura*—loss of lamina dura.
- *Angle of mandible*—thickness of cortex of mandibular angle is reduced.
- *Medullary spaces*—increase in medullary space at the expense of trabeculae. Other bones may show areas of sclerosis.

Diagnosis

- *Clinical diagnosis*—myopathy, neuropathy can give clue to diagnosis.
- *Radiological diagnosis*—generalized loss of bone density with thinning of bony cortex will aid in diagnosis.

Management

- *Vitamin D*—plasma Ca^{++} and K^+ are kept as near as normal.
- *Vitamin D*—hypocalcemia is corrected by giving hydroxylated synthetic analogues of vitamin D.
- *Phosphate binding agents*—hyperphosphatemia is controlled by dietary restriction of foods with high phosphate content (like milk, cheese, eggs) and the use of phosphate binding drugs.

Uremia

It is a clinical condition caused by the retention of urinary constituents in the blood. The characteristic symptoms are headache, itching, nausea, convulsions, and eventually coma. Patient’s breath may have urinous odor.

There is unpleasant taste and dryness of mouth. There is erythematous, pseudomembranous type of uremic stomatitis. If pseudomembrane is removed, it will expose dry, red, swollen mucosa. The oral bleeding tendency, often observed in patients with uremia, is due to uremic thrombopathy. Patient has an increased disposition to develop oral candidiasis.

Kidney Transplantation

In order to prolong life in patients with end stage renal failure, renal transplantation is done. It involves surgical removal of kidney from living first degree relative such as sibling, parent, child or a recently expired source. Kidney transplant patient usually receives a continuous regimen of immunosuppressive medication to ensure graft survival.

Clinical Features

- Majority of clinical manifestation occur secondary to immunosuppressive drugs.

- *Buffalo hump*—steroids are responsible for cushingoid effect, characterized by rapidly acquired adiposity about the upper portion of the body, mooning of face and tendency to become round shouldered and develop a 'buffalo hump' at the base of neck.
- *Infection*—there is increase susceptibility to fungal infection due to decreased migration and impaired phagocytic function of leukocytes and macrophages.
- *Hepatic dysfunction*—cyclosporine can cause hepatic dysfunction because metabolism occurs exclusively in the liver.

Oral Manifestations

- *Oral mucosa*—pale mucosa with diminished color demarcation between attached gingiva and alveolar mucosa.
 - *Salivary gland*—enlarged salivary glands and decreased salivary flow resulting in xerostomia.
 - *Odor and taste*—odor of urea on breath and metallic taste.
 - *Teeth*—enamel hypoplasia, dark brown stain on crowns, dental malocclusion, and low caries rate.
 - *Gingiva*—increase in calculus formation, low grade gingival inflammation and bleeding from gingiva and mouth.
 - *Candidiasis*—candidal infection can occur on tongue.
 - *Other*—petechiae, ecchymosis, erosive glossitis, burning and tenderness with dryness of mucosa. Dehiscence of wounds also occurs.
- *Defer dental treatment*—after transplantation, routine dental treatment should be postponed until maintenance dose; of immunosuppressive agents is reached.
 - *General guidelines for managing the kidney transplant patient who is taking corticosteroids:*
 - Always use long acting anesthetics agents such as bupivacaine.
 - Use mild sedatives for apprehensive patients. Use postoperative pain medications, when indicated.
 - Patients who are receiving alternate day corticosteroid therapy should be treated on off day.
 - If the patient is receiving daily therapy, then the dosage of oral steroids should be doubled the day before, the day of and 2 days after treatment.
 - Alternatively, single dose of 100 mg dose of hydrocortisone hemisuccinate should be given intramuscularly just before the treatment and extra 20 mg dose should be given early that evening.
 - *Following steps should be taken for proper management of renal transplant patients:*
 - The patient's physician should be consulted to coordinate treatment.
 - Broad spectrum antibiotics should be used in prophylactic medication of the patient, before dental treatment, because of decreased immune status.
 - Complete blood count with differential and platelet count should be obtained before any surgical procedure as corticosteroids can cause myelosuppression.

Radiological Features

- *Demineralization of bone*—there is demineralization of bone with loss of bony trabeculation.
- *Ground glass appearance*—sometimes, ground glass appearance can be seen.
- *Other finding*—loss of lamina dura, socket sclerosis is other radiological findings.

Diagnosis

Diagnosis can be made by history.

Dental Considerations

- *Elimination of source of infection*—Oral infection in transplant patients has been reported as frequently as pneumonia or urinary tract infection. Prompt diagnosis of the site and cause of infection in immunosuppressed patient should be on high priority. Identification of pathogens should be performed with culture, sensitivity, smear, aspiration technique or biopsy. The successful management of transplant patient begins before transplantation, with the preoperative elimination of potential sources of infection.

Disorders of Gastrointestinal Tract

Hepatitis

It is an acute, inflammatory and infective infection caused by hepatitis A, B, C, D and NANB viruses. Dentists are 3 to 4 times more likely to be exposed to hepatitis than with general population.

Types

- *Hepatitis A*—it is also called as *infectious hepatitis*. It is endemic and occurs in person who lives in poor living condition. Spread of hepatitis A is by orofecal route. The period of infectivity is highest during the week before the onset of clinical symptoms. It is common in children, primary and nursery school age. Once it occurs it gives life long immunity.
- *Hepatitis B*—it is also called *serum hepatitis*. It is transmitted by parenteral route, for example, blood and blood products and contaminated needles. It can also be transmitted due to close personal contact. It is also found in saliva, semen and vaginal secretions. 5 to 10%

of infected person remain as carriers. Hepatitis B tends to have greater mortality and morbidity than hepatitis A.

- **Hepatitis C**—it is caused by hepatitis C virus and it is responsible for sporadic viral hepatitis in intravenous drug user, and in patient with renal dialysis. It has got less clinical severity as compared to hepatitis B. It is associated with lichen planus, lymphoma, and cryoglobulinemia.
- **Hepatitis D**—it is called by delta agents or hepatitis D virus. It is incomplete virus carried within hepatitis B virus and will replicate in presence of HBsAg. So this infection occurs in association with hepatitis B infection. It is spread by parenteral route. It has got same clinical features as that of hepatitis B.
- **Hepatitis G**—it is caused by hepatitis G virus or GB virus-C. Many of this patient is infected with hepatitis C virus. It produces clinical symptoms less severe to hepatitis C.
- **Posttransfusion hepatitis**—this is caused by newer hepatitis virus like TTV (transfusion transmitted virus), SEN D and SEN H. These virus are not transmitted during dentistry.

Phases of Hepatitis

- **Prodromal phase**—is of 1-2 weeks; symptoms like anorexia, nausea, malaise and fever occur.
- **Icteric phase**—(6-8 weeks) anorexia, nausea, vomiting and pain in the right upper quadrant of abdomen. Hepatomegaly and splenomegaly may also be seen.
- **Convalescent (recovery) phase**—symptoms disappear, but abnormal liver function values may persist.

Clinical Features

- **Incubation period**—in this, most cases resolve completely within 4 months after onset of symptoms but, some end in fulminating disease and others progress to chronic hepatitis.
- **Symptoms**—systemic complains include malaise, arthralgia, morbilliform skin rash, anorexia, vomiting and myalgia. Patient has high grade fever with tenderness and enlargement of liver. Patient also complains of upper respiratory tract infection, distaste for cigarette, fever and enlargement of liver.
- **Signs**—jaundice, darkening of urine, splenomegaly and whitish stools occurs.
- **Oral manifestation**—icterus of the oral mucosa, which is seen on the palate and in the sublingual region.

Laboratory Findings

- **Plasma bilirubin level**—plasma bilirubin level excess of 3 mg/dl.
- **SGPT SGOT level**—SGPT, SGOT levels increase 10 times in hepatitis.

- **Alkaline phosphate level**—liver enzymes such as alkaline phosphatase and lactic dehydrogenase show slight elevation.
- **WBC**—WBC shows leukopenia, leukocytosis and atypical lymphocytes.
- **Australia antigen**—demonstration of HBsAg or Australia antigen.

Management

- **General treatment**:
 - **Symptomatic treatment**—like bed rest and prevention by isolation of blood, saliva contaminated objects; use of gloves and apron and sterilized instruments are must.
 - **Nutrition**—a high calorie diet should be given. It is usually given in morning because many patients experience nausea in evening.
 - **Drugs**—there is no specific drug useful for it. But interferon and ribavirin have been tried, with some success in chronic hepatitis.
 - **Prevention**—the patient should avoid salivary transmission to others by avoiding kissing, spitting and sharing food, cigarettes, utensils and sexual contact.
- **Hepatitis A**—it is self limiting and resolves with in one month mortality is very low. Treatment is usually symptomatic.
- **Hepatitis B**—chronic hepatitis B infection can be treated with lamivudine or interferon. Treatment is needed for 1 to 3 years.
- **Hepatitis C**—chronic hepatitis C is treated by combination of ribavirin, interferon alpha or pegylated interferon.
- **Hepatitis D**—drug treatment with alpha interferon is effective.
- **Hepatitis G**—alpha interferon is also effective against hepatitis G.

Prevention

- **Hepatitis A**—people who are known to have contact with a patient, such that they may have ingested minute amounts of fecal material or have been injected with as little as 0.0004 ml of infected blood, should be given prophylactic gamma globulin injections.
- **Hepatitis B**—a vaccine has been prepared from the plasma of asymptomatic carriers of hepatitis B. It is composed of non-infectious hepatitis B surface antigen particles. It is recommended in all high-risk groups.
- **Hepatitis C**—there is no vaccine available for this hepatitis. Preventing measure like not sharing personal item with bloodstain, not sharing needle in drug user, avoid having tattoo without strict health precaution.

- *Hepatitis D*—vaccination against hepatitis B will also give protection against hepatitis D.

Dental Considerations

- *Risk to dental professional*—hepatitis B, C and other types can be transmitted to the dentist by blood contaminated needles or instrument stick from an infected patient in acute phase of disease.
- *Clotting factors assessment*—if surgery is necessary, obtain preoperative prothrombin time and bleeding time, as in liver diseases deficiency of clotting factor may be present.
- *Universal infection precaution*—dental personnel may act as a source of infection to patient. Dentists who are carriers of HBV and who do not practice universal infection control precautions can transmit the infection to patient. At the same time it is required to avoid infection from patient to be transmitted to dental personnel.
- *Strict aseptic procedure*—strict aseptic procedure—use of masks, gloves for all persons is a must.
- *Minimize aerosol production*—minimize aerosol production by using a slow speed handpiece and using air syringe.

Inflammatory Bowel Disease

Chronic infectious diseases of small intestine and large bowel are of interest for dentist because of the oral manifestations that have been reported. In some of the cases it can be initial finding.

Types

- *Ulcerative colitis*—it is an inflammatory disease that is confined to the mucosa and submucosa of colon.
- *Crohn's disease*—it is an inflammatory disease involving the entire wall of a portion of small gut.

Clinical Features

- *Age*—it is seen in teenagers as compared to adults.
- *Symptoms*—upper and lower abdominal pain, usually cramping in nature along with fever and episodes of bloody diarrhea. Weight loss and malnutrition may occur in these patients.
- *Anorectal fistulae*—anorectal fistulae develop, as well as segmental narrowing of the intestinal lumen and rectal bleeding.
- *Erythema nodosum*—in some cases, there is presence of erythema nodosum of skin.

Oral Manifestations

- *Site*—the most frequently affected areas are the buccal mucosa, vestibule and lip.

Fig. 33-8: Linear ulceration in buccal vestibule with diffuse nodular swelling (Courtesy Dr Milind Chandurkar).

- *Aphthous ulcer like lesion*—Lesions resembling aphthous ulcer may occur.
- *Orofacial granulomatosis*—an oral granulomatous lesion occurs as nodular mass in mucobuccal fold.
- *Cobblestone appearance*—it shows cobblestone pattern of swelling on buccal mucosa.
- *Linear ulceration*—there is linear hyperplastic fold with ulceration (**Fig. 33-8**).
- *Swollen lip*—it appears swollen and indurated.

Diagnosis

- *Clinical diagnosis*—linear ulceration with granulomatous lesion with gastrointestinal symptoms may give clue to diagnosis.
- *Laboratory diagnosis*—biopsy shows non-necrotizing granulomatous inflammation.

Management

- *Sulfa drugs*—patient can respond to sulfasalazine. The metabolites of which are concentrated in the intestinal tissue.
- *Corticosteroids*—corticosteroids such as prednisolone can be use in combination with immunosuppressive drug azathioprine. Therapy is being used in increasing frequency in inflammatory bowel disease.
- *Management of oral lesion*—oral lesion are treated by topical and intralesional corticosteroids. Persistent lesions are treated with thalidomide.

Dental Considerations

- *Precaution*—it may necessitate alteration of dental therapy or special precautions on the part of dentist.

- *Corticosteroids therapy*—patients on corticosteroid therapy may develop both, hyperglycemia and osteoporosis, both of which have adverse effect on contemplated dental therapy.

Gastroesophageal Reflux Disease

Gastroesophageal reflux disease is a common condition. Regurgitation of gastric contents will reduce the pH of the oral cavity below 5.5. This acidic pH of oral cavity begins to dissolve enamel of teeth. It is most commonly seen on the palatal surfaces. Erosion of the enamel exposes the underlying dentin, which is a softer, opaque material. The extent of erosion depends on the frequency and the quantity of exposure along with the duration of disease. Newly exposed dentin is smooth and shiny, while dentin from previous exposures may be stained.

Erosion differs from dental caries in that it is a hard, dished-out area where enamel has dissolved and the underlying dentin is exposed. On the other hand, caries reveals soft, discolored dentin and results from the bacterial breakdown of sugars on the surface of the teeth.

The prevalence of caries is not increased in persons with GERD, possibly because the acidic environment interferes with the formation of the dental biofilm. Good dental care and control of acid helps decrease the prevalence of erosion. However, once the erosion occurs, it is irreversible and can only be treated with surgical restorative procedures. Therefore, early recognition and patient education is the most effective treat.

Jaundice

It is a symptom rather than a disease, resulting from excess of bilirubin in circulation. Jaundice can be recognized by color of skin, oral mucous membrane and sclera of the eyes. There is yellowish discoloration of skin, muscle membrane and sclera of eyes due to increased level of bilirubin and deposition of bile pigment tissues. Jaundice appears when serum concentration exceeds 2 to 3 mg /dl.

Types

- *Hemolytic jaundice*—results from an excessive hemolysis or destruction of erythrocytes produced by an inherited abnormality in the cells, some acute diseases and certain drugs or poisonous agent or acquired immune disease.
- *Obstructive jaundice*—caused by gallstone and external pressure on biliary passage, associated with infection or neoplastic lesions.
- *Hepatocellular jaundice*—it can be caused by diseases such as hepatitis and alcoholic and postnecrotic cirrhosis.

Causes

- *Hemolysis*—there is increased destruction of red blood cells with excessive pigment production.
- *Gilbert's syndrome*—it is a common form of congenital hyperbilirubinemia.
- *Transport disease*—inability of the liver to transport bilirubin into the bile.
- *Others*—jaundice can occur due to primary biliary cirrhosis, cystic fibrosis and traumatic biliary strictures.

Clinical Features

- *Urine*—increased urobilinogen excretion causes the urine to turn dark.
- *Anemia*—pallor occurs due to anemia and thus can be noticed on nails.
- *Splenomegaly*—it occurs due to excessive reticuloendothelial activity.
- *Others*—pruritus, abdominal pain and pale stools can also occur in jaundice.
- *Icterus*—yellowish discoloration of sclera of eye is also present. This yellow discoloration is caused by hypercarotenemia (**Fig. 33-9**).

Oral Manifestations

- *Icterus of oral mucosa*—it can be seen on palate and in the sublingual area.
- *Spontaneous bleeding*—in cases of severe jaundice patient may present with spontaneous bleeding in the oral cavity or severe bleeding following oral surgical or periodontal operation.

Diagnosis

- *Clinical diagnosis*—icterus and yellow discoloration of skin can easily be noted
- *Laboratory diagnosis*—serum bilirubin level is increased

Fig. 33.9: Icterus seen in eyes of patient who is suffering from jaundice. Note also yellowish discoloration of facial skin (Courtesy Dr Milind Chandurkar).

Management

- *Consult the physician*—if dentist discovers the jaundice patient should be sent to physician for further treatment and consultation.

Diseases of Esophagus

- *Plummer-Vinson syndrome*—It is characterized by an esophageal web with resulting dysphagia, particularly in the upper segment of esophagus, as well as by atrophic changes in the mucous membrane of mouth and by a hypochromic microcytic anemia.
- *Dysphagia*—it is difficulty in swallowing which may result from mechanical obstruction in the esophagus or from disorders of the nervous system that prevent the coordinated reflex contraction of the appropriate muscles.
- *Esophageal ulcer*—it can be associated with tetracycline therapy. It occurs more often after dry swallow of tablet or capsule, especially at bedtime. The patient complains of severe retrosternal burning pain.
- *Dental consideration*—due to unique position in treating in the oral cavity, dentist may be the first to detect this condition and should promptly refer it to physician for early diagnosis and prompt treatment. Special precautions should be taken while treating these diseases, to avoid aspirations secondary to dental procedures. Patients who have been prescribed tetracycline should be warned to swallow the capsule or tablet with adequate amount of liquid.

Peptic Ulceration

Ulceration of the mucosa of gastrointestinal tract caused by the action of protein-digesting pepsin on mucosa is one of the most common disease affecting GIT and one of the most common disease to afflict man.

Predisposing Factors

- *Acid production*—the normal stimuli for acid secretion include the thought, sight, smell or taste of food, which is mediated by the anterior hypothalamus, acts by vagal stimulation directly on the mucosa of stomach to cause acid production.
- *Hypoglycemia and mental stress*—hypoglycemia and mental stress also act by the same mechanism to increase stomach acid production.
- *Gastrin production*—presence of food in the antrum of stomach wall, by the mechanism of distention, cause increased production of the hormone gastrin, which acts directly on the acid producing cells of stomach.

Clinical Features

- *Site*—it usually affects lower one third of esophagus, stomach and the duodenum in increasing order of frequency.
- *Symptoms*—the most common symptom is epigastric pain, usually occurring either just before eating or 1-3 hours after eating. The pain is burning in nature and associated with nausea and vomiting. It is characteristically relieved by food. If ulceration is large enough to erode an artery, bleeding may be a primary symptom.
- *Coffee ground vomitus*—it is manifested by black tarry stools or more rarely by vomiting of blood. The vomitus appears like 'coffee ground because of blood reaction with acid.

Oral Manifestations

- *Site*—vascular formation is more commonly seen at the inner surface of the labial commissure and is more common in males than females.
- *Vascular malformation*—it is rarely manifested in the oral cavity but in certain cases, vascular formations of lip are also found in peptic ulcer. The vascular formations are of three types:
 - *Microcherry*—it is small, sharply circumscribed, red dot type of lesion.
 - *Glomeruli*—a conglomeration of tortuous, thin walled vessels 1-2 mm or more in size.
 - *Venous lakes*—dilated submucosal vein resembling a miniature varix.
- *Complication*—massive bleeding, obstruction, perforation and intractability to medical treatment.

Diagnosis

- *Clinical diagnosis*—coffee ground vomitus with vascular malformation of lip may give clue to diagnosis.

Management

- *Sedatives*—it is given to reduce mental stress, when it is the etiological factors.
- *Antacids*—it is given to neutralize the excess acid present in stomach. When antacids are given they usually are prescribed 1-3 hours after meals and at bedtime. Most antacids are combination of calcium carbonates, magnesium hydroxide and aluminum hydroxide.
- *Anticholinergic drugs*—it is given to decrease production of acids by the gastric mucosa.
- *H₂ histamine-receptor blocker*—such as cimetidine, famotidine, nizatidine or ranitidine. It blocks the action of histamine on the gastric parietal cells, thus reducing food stimulated acid secretion.

- *Sucralfate*—it act by covering and protecting the ulcer, thus promoting the healing.
- *Omeprazole*—it suppress gastric acid secretion by inhibiting an enzyme system at the secretory surface of the gastric parietal cells.

Dental Considerations

- *Drugs used*—the dentist should avoid administration of drugs that exacerbate ulceration, the most common of which is aspirin or one of its related compound. Patients who are given oral penicillin should be given penicillin V, instead of penicillin G, because of resistance of the former to gastric acid. Patient with anticholinergic drugs often present with dry mouth, which may present problems because of increase in the viscosity of mucus and discomfort in wearing complete dentures. There is also increased incidence of cervical caries. Many antacids contain calcium, magnesium and aluminum salts that bind both, erythromycin and tetracycline. These antacids may decrease the absorption of antibiotics by as much as 75 to 85%, if administered within 1 hour of such antacid therapy.
- *Sedation before treatment*—a patient who reacts in a particular stressful way to dental procedure should be sedated before dental treatment.

Neuromuscular Disorders

Auriculotemporal Syndrome

It is also called as *Frey's syndrome* or *gustatory sweating*. It is characterized by flushing and sweating of facial skin along the region of distribution of auriculotemporal nerve. It is an unusual phenomenon which arises as a result of damage to the auriculotemporal nerve.

Pathogenesis

- *Auriculotemporal nerve*—it gives sensory supply to the preauricular and temporal region, carries parasympathetic fibers to parotid gland.
- *Scar formation*—after damage to nerve scar formation occur around the nerve.
- *Re-established innervations*—the fibers regenerate, become misdirected and become connected with sympathetic nerve fibers of sweat gland and blood vessels of the facial skin.
- *Sweating and vasodilation*—parasympathetic fibers would therefore induce salivation; inadvertently stimulate the preauricular-dermal sweat gland and arterioles, causing vasodilation.

Variation of Frey's Syndrome

- *Chorda tympani syndrome*—it occur when there is injury to the submandibular gland.
- *Gustatory lacrimation syndrome*—this occur when there is injury to facial nerve proximal to geniculate ganglion.

Etiology

- *Surgical operation*—it follows surgical operations such as removal of a parotid tumor or ramus of mandible. It may follow superficial parotidectomy.
- *Parotitis*—parotitis of some type may damage the auriculotemporal nerve.
- *Congenital*—it may be due to birth trauma.
- *Drainage of abscess*—it may caused by inadvertent incision for drainage of parotid abscess.
- *Transaxonal excitation*—some cases of gustatory sweating appear due to transaxonal excitation, rather than actual anatomic misdirection of fibers.
- *Radical neck dissection*—some cases may develop after radical neck dissection.

Clinical Features

- *Age and sex*—there is no age and sex predilection.
- *Symptoms*—the patient exhibits preauricular flushing and sweating of the involved side of face, following ingestion of food or visual stimulation by food. Patient may sometimes feel pain while eating. The severity of sweating is increased by tart food. Profuse sweating may be evoked by parenteral administration of pilocarpine or eliminated by the administration of atropine. Local skin temperature can increase up to 2 °C.
- *Crocodile tears*—in it patient exhibits profuse lacrimation when food is eaten particularly hot and spicy food.
- *Cutaneous hyperesthesia*—presence of cutaneous hyperaesthesia in front and above the ear, the area supplied by the auriculotemporal nerve.

Diagnosis

- *Minor starch iodine test*—this test is done for the diagnosis. The test is as follows:
 - *Coating with 1% iodine*—preauricular area is coated with 1% iodine.
 - *Application of starch*—area is dried after application of iodine. After drying starch is applied on the skin.
 - *Sweating stimulant*—patient is given chocolate to induce sweating.
 - *Positive minor test*—bluish black discoloration is seen in area of sweating.

Management

- *Nerve dissection*—intracranial division of auriculo-temporal nerve has been reported to be successful.

- *Inserting physical barrier*—to prevent re-innervations of the sweat gland, many clinicians prefer to insert a physical barrier at the time of surgery. Materials used are porcine dermal collagen, autogenous tissue like fascia lata, temporalis muscle.
- *Pharmacological agents*—pharmacological agents used are atropine, scopolamine, and glucopyrrolate. It can be used topical or in injection form. Most commonly given injection is 1% glucopyrrolate lotion or cream.
- *Botulinum toxin*—this is the recent advance in the management of Frey's syndrome. BTX is the neurotoxin that blocks the release of acetylcholine by irreversible binding to presynaptic cholinergic autonomic nerve terminals.
- *Antimuscarinic agent*—systemic antimuscarinic agent oxybutynin chloride can be useful in treatment of Frey's syndrome.
- *Diluted formalin soaks*—the use of local skin application of diluted formalin soaks is well documented. It prevents hyperhydrosis. It act by blocking the effect of acetylcholine on sweat receptor, thereby inhibiting sweating locally. It should be applied before function to prevent embarrassing symptoms.

Bell's Palsy

It is also called as 7th nerve paralysis or *idiopathic facial paralysis*.

Pathogenesis

- *Normal course*—the cortical tract communicating with the motor nucleus ambiguous of facial nerve crosses over to get innervated into the lower face musculature. Upper face fibers are ipsilateral proximal to the nucleus.
- *Lower face palsy*—a cortical lesion will cause contralateral lower face palsy.
- *Total hemifacial palsy*—lesions of brainstem, main trunk or peripheral fibers will result in total hemifacial paralysis.

Etiology

- *Cold*—it usually occurs after exposure to cold. But many workers believe that it is a chance finding.
- *Trauma*—it may be a causative factor as Bell's palsy occurs after extraction of teeth and after injection of local anesthesia. Extraction and injection may cause damage to the nerve and subsequent paralysis.
- *Surgical procedure*—surgical procedures such as removal of parotid gland tumor in which the facial nerve is sectioned can also cause facial paralysis.
- *Ischemia*—it may caused by ischemia of the nerve near the stylomastoid foramen, resulting in edema of the

nerve, its compression in the bony canal and finally, paralysis.

- *Familial*—familial and hereditary occurrence is also reported in cases of Bell's palsy.
- *Facial canal and middle ear neoplasm*—these are usually associated with sensorineural hearing loss where 7th nerve palsy is a feature.
- *Tumors*—tumors of cranial base, parapharyngeal space and infratemporal fossa often cause 7th nerve palsy.
- *Other causes*—other causes like multiple sclerosis, atmospheric pressure change, and pregnancy can be triggering factors of facial paralysis.

Clinical Features

- *Age and sex*—women are more commonly affected than men and usually, it occurs in the middle age group. It arises more frequently in spring and fall, than at any other time of the year.
- *Onset*—it begins abruptly as paralysis of the facial musculature, usually unilaterally.
- *Prodromal symptoms*—in some cases, it is preceded by pain on the side of the face which is ultimately involved, particularly within the ear, temple, and mastoid area or at the angle of the jaw.
- *Symptoms*—speech and eating is difficult and occasionally, taste sensation on the anterior portion of tongue is lost or altered. Food is retained in the upper and lower buccal and labial folds due to weakness of buccinator.
- *Eye*—on the affected side, eye cannot be closed and wrinkles are absent on that side. There is watering of eye, which leads to infection.
- *Facial features*—when the patient smiles, the paralysis becomes obvious since the corner of the mouth does not rise nor does the skin of the forehead wrinkles or the eyebrows raise (**Fig. 33-10**).

Fig. 33-10: 7th nerve paralysis showing paralysis on left side of patient (Courtesy Dr Datarkar).

- *Mask like face*—the patient has a typical mask-like or expressionless appearance.
- *Drooling of saliva*—the muscular paralysis manifests itself by dropping of the corner of mouth, from which saliva may dribble.
- *Syndrome associated*—it is associated with Melkersson-Rosenthal syndrome.

Diagnosis

- *Clinical diagnosis*—slurred speech, mask like face, drooling of saliva can diagnose this condition.

Management

- *Vasodilator*—the use of vasodilator drug like histamine has been proved beneficial in some cases.
- *Surgical decompression and anastomosis of nerve*—surgical anastomosis of nerves has been carried out, especially with facial and hypoglossal nerve; thus can restore partial function.
- *Nicotinic acid*—administration of physiologic flushing dose of nicotinic acid.
- *Other*—systemic steroids or ACTH injection have been successful in treating Bell's palsy.

Motor System Disease

Motor system disease is neurodegenerative disorder which is characterized by progressive weakness and wasting of muscles.

Etiopathogenesis

- *Degeneration of motor neuron cells*—the motor system disease results from degeneration of the motor neuron cells of cranial nerves, anterior horn of spinal cord and pyramidal tract.
- *Genetic*—it is transmitted as autosomal recessive disorders.

Types

- *Progressive muscular atrophy*—it is seen in childhood.
- *Progressive bulbar palsy*—it is seen in children and young adults.
- *Amyotrophic lateral sclerosis (Lou Gehrig disease)*—it is seen in middle age.

Clinical Features

Progressive muscular atrophy

- *Age and sex*—it usually occurs in childhood. It shows a strong hereditary pattern, affects males more frequently than females.
- *Symptoms*—the initial symptoms usually consist of difficulty in walking with leg pain and paresthesia.

- *Steppage gait or stork-leg appearance*—patient notices atrophy of foot, leg and hand muscles ultimately occurs with the appearance of a typical foot-drop, steppage gait and stork-legs.

Progressive bulbar palsy

- *Age and sex*—it generally occurs in the children and young adults. There is no gender predilection.
- *Symptoms*—It is characterized by difficulty in swallowing and phonation, hoarseness, facial weakness and weakness of mastication. Chewing is difficult as facial muscles becomes weakened.
- *Signs*—atrophy of facial, masseter, temporal muscles and tongue, with fasciculation of the face and tongue. There is also impairment of palate and vocal cords.

Amyotrophic lateral sclerosis

- *Age and sex*—it generally occurs between the ages of 40 and 50 years and affects males more frequently.
- *Precipitating factors*—precipitating factors include fatigue, alcohol intoxication and trauma. Infections like syphilis, influenza, typhus and epidemic encephalitis can also lead to amyotrophic lateral sclerosis.
- *Symptoms*—the initial symptoms consist of weakness and spasticity of limbs, difficulty in swallowing and talking with indistinct speech and hoarseness.
- *Signs*—atrophy, flaccidity, symmetric weakness, slowness of movements, and impairment or loss of palatal movements may also occur.
- *Fasciculation*—there is small, synchronous, subcutaneous muscle contraction of the shoulders and thighs.
- *Tongue*—in earlier stages, the tongue is slightly weakened, leaving articulation relatively unaffected. In the middle stages, a gradual and generalized weakening of tongue occurs, accompanied by spasticity which results in reduced rate, range and force of articulatory tongue movements. In the later stages, there is virtually unintelligible articulation.

Diagnosis

- *Clinical diagnosis*—dysphagia, steppage gait, stork-leg appearance, tongue weakness and fasciculation are diagnostic point of motor neuron disease.

Management

- *Antiglutamate agents*—antiglutamate agent riluzole shows some improvement in this disease. As such there is no specific treatment for this disease and it is usually fatal.

Multiple Sclerosis

It is also called as *disseminated sclerosis*. This disease affects central nervous system. It is autoimmune disease.

Etiology

- *Allergic*—the lesions are allergic hypersensitivity manifestations of the nervous tissue due to antigen-antibody reactions.
- *Altered coagulation of blood*—the lesions are due to scattered venous thromboses in the nervous system associated with altered coagulation of blood.
- *Transitory local vasoconstriction*—the lesions are due to repeated, transitory localized vasoconstriction in various portions of the nervous system, precipitated by emotional disturbances or fatigue.

Clinical Features

- *Age and sex*—it occurs chiefly in younger age group with an onset of symptoms between the ages of 20 and 40 years. There is slight female predilection with familial occurrences.
- *Symptoms*—fatigability, weakness and stiffness of the extremities with ataxia or gait difficulty, involving one or both legs. Superficial or deep paresthesia. Personality and mood deviation towards friendliness and cheerfulness.
- *Signs*—variety of ocular disturbances including visual impairment as a manifestation of retrobulbar neuritis, nystagmus and diplopia.
- *Staccato speech*—staccato (a series of short, detached sound or words) type of speech.
- *Charcot's triad*—it consist of intentional tremors, nystagmus, dysarthria and scanning speech.

Oral Manifestations

- *Jaw weakness*—facial and jaw weakness occur in some patients.
- *Reduced mouth opening*—this may occur due to stiffness and weakness of muscle (**Fig. 33-11**).
- *Trigeminal neuralgia*—this occurs in multiple sclerosis patients and it usually bilateral.
- *Facial palsy*—this can also be present in the multiple sclerosis.

Fig. 33-11: Multiple sclerosis patient showing reduce mouth opening due to stiffness of facial muscle.

Diagnosis

- *Clinical diagnosis*—bilateral trigeminal neuralgia with speech difficulty and vision problems will diagnose this condition.

Management

- *Drug treatment*—beta interferon, mitoxantrone, and glatiramer can be effective in this patient. Medication to reduce muscle fatigue can also be used.
- *Physical and occupational therapy*—this can be use to patient up to certain extent.

Cerebral Palsy

The term cerebral palsy refers to a group of disorders with motor manifestations due to nonprogressive brain damage, occurring before or after birth.

Causes

- *Anoxia and ischemia*—anoxia and ischemia during labor can cause cerebral palsy.
- *Congenital infection*—congenital infection like toxoplasmosis, rubella, cytomegalovirus disease, herpes simplex, syphilis and influenza can also cause cerebral palsy.

Clinical Features

- *Forms*—cerebral palsy can be manifested in spastic, dyskinetic, ataxic or a combination, affecting one or four limbs.
- *Spastic form*—legs are commonly involved. Speaking problems with dysarthria, chewing and swallowing difficulty. Sometime, there are seizures associated with mental retardation.
- *Dyskinetic form*—it is characterized by athetotic purposeless movement, involving both agonist and antagonist muscles, which is increased by voluntary activity. Head movement and facial grimacing are characteristic.
- *Lead pipe type movement*—this occur due to excessive muscle tone.

Oral Manifestations

- *Sialorrhea*—drooling of saliva, this can lead to both functional and esthetic inconvenience.
- *Enamel hypoplasia*—an increased incidence of enamel defects.
- *Malocclusion*—this is present due to abnormal muscle behavior. Upper teeth are inclined.
- *Maxilla*—maxillary arch is tapered and ovoid in shape with high arch palate.

Diagnosis

- *Clinical diagnosis*—lead pipe type of movement with hemiplegia will lead to the diagnosis. There is also delay in development of motor skill.

Management

- *Physiotherapy* should be instituted as early as possible, in order to prevent contractures.
- *Orthopedic surgery* can be helpful in some cases.
- *Drugs therapy*—in case of seizures, *drugs therapy* like dantrolene sodium diazepam or L-dopa may be used.
- *Anti-cholinergic drugs*—for drooling of saliva, *anticholinergic drugs* such as benzhexol, atropine and scopolamine are used.

Epilepsy

It is a disorder, which results due to a sudden discharge by cerebral neurons, resulting in convulsive movements. It can cause sensory and motor abnormalities as well as loss of consciousness. Convulsions can also be seen with high grade fever, brain tumor, head injury, hypoglycemia, hypocalcemia, and drug toxicity.

Types

- *Grand mal*—it is most common type of seizure which can occur alone or with other types of seizure.
- *Petit mal*—it is the second most common type and it occurs without aura and with little or no clonic or tonic movements.
- *Psychomotor*—the seizures are preceded by an aura, which is often a hallucination or a feeling of déjà vu.
- *Jacksonian*—in it, attack begins in one part and spreads gradually.
- *Simple partial seizure*—it originates from one localized area of the brain and does not feature loss of consciousness.
- *Complex partial seizure*—it is same as psychomotor, with impairment of consciousness.
- *Status epilepticus*—it is the period of recurrent seizure attacks, without recovery between each attack.

Clinical Features

- *Grand mal*—it begins in childhood. There is warning followed by loss of consciousness.
 - *Aura phase*—a grand mal seizure begins with aura in which patient experiences epigastric discomfort, an emotion or hallucination of hearing, vision or smell.
 - *Tonic phase*—the aura is followed, in seconds to minute, by unconsciousness, cry, and tonic muscle spasms. There is also breathlessness due to spasm of respiratory muscles and the patient becomes cyanotic.

- *Clonic phase*—the tonic phase is followed by clonic phase composed of convulsive jerky movements, incontinence and tongue biting. Jaw is clamped shut and there is foaming at the mouth. Patient may injure himself, if he is near hard or sharp object.
- *Postictal state*—a postictal state is characterized by headache, confusion, lethargy, occasional temporary neurological deficit and deep sleep.
- *Petit mal*—they are present exclusively in children and frequently disappear during second decades of life. The patient loses his consciousness and appears to stare into the space. He will continue his normal activity immediately after the seizure.
- *Psychomotor*—during the seizure, the patients exhibit purposeless movements and bizarre behavior. Patient may wander about aimlessly, may get undressed or exhibit violent behavior during the seizure.
- *Jacksonian*—the seizure begins with clonic movement of a distal portion of extremities or the face. The convulsive movement spread up to the affected limb, becomes generalized and causing loss of consciousness.

Diagnosis

- *Clinical diagnosis*—tonic muscle spasm, convulsive jerky movement with headache and confusion will diagnose this condition.

Management

- *Immediate care of seizures*—you should move person away from danger like fire, water, machinery and furniture. After convulsion ceases it turns into recovery position, i.e. semiprone position. Do not insert anything in the mouth as tongue biting occurs at the start of seizure, so it cannot be prevented. If convulsion continues for more than 5 minutes or recur without person regains consciousness, summon urgent medical attention. Give intravenous anticonvulsants, i.e. diazepam, if convulsion continues or repeated. Airway should be kept patent during the epileptic fits.
- *Anticonvulsive drug therapy*—the drug of choice for grand mal, psychomotor and Jacksonian seizure is phenytoin (Dilantin), often in combination with phenobarbital. Patient resistant to it are given primidone. Drug of choice for petit mal is ethosuximide because of few side effects associated with it. Other drugs used are trimethadione, paramethadione and acetazolamide.

Dental Considerations

- *Gingival enlargement*—patients taking anticonvulsant drug such as phenytoin, develop gingival hyperplasia which may exacerbate due to local inflammatory factors. You should also look for level of drug in the gingival tissues and the effect of drug on gingival mast cells.

- *Side effects of phenytoin*—other side effects of phenytoin are megaloblastic anemia, lymphadenopathy, connective tissue and bone changes. Phenytoin blocks the effect of parathyroid hormone on bone, resulting in bone and root changes.
- *Drug interference*—aspirin, azole and metronidazole can interfere with phenytoin. So this drug is contraindicated in epilepsy.

Parkinson's Disease

It is a major cause of chronic disability in patients over 50 years of age.

Causes

- *Depletion of neurotransmitter*—it is caused by depletion of neurotransmitters, dopamine and norepinephrine in the basal ganglion.
- *Other disease*—some are caused by encephalitis, trauma, carbon monoxide intoxication, atherosclerosis, metal poisoning and brain tumor.

Clinical Features

- *Triad*—the triad is rigidity, tremor and bradykinesia (slowness in the initiation of movements).
- *Onset*—the onset is insidious. Mild stiffness of muscle of the extremities and tremor of hand are early signs.
- *Pill-rolling movement*—the typical hand tremors are called as pill-rolling movements and are caused by movement of thumb and fingers rubbing against one another.
- *Gait*—walking becomes more difficult and patients develop a slow shuffling gait in a stooped position because of the inability to stand straight.
- *Speech*—speech becomes slow owing to lack of muscle control (dysarthria) and as the disease progresses there is a decrease in all voluntary movements and increase in tremor.

Oral Manifestations

- *Appearance of face*—rigidity of facial muscle is common. The loss of flexibility gives the patient an expressionless or masklike face.
- *Droping*—the muscle rigidity also causes difficulty in swallowing, resulting in drooling.
- *Tremors*—tremor of tongue and mandible are also common, making speech and eating difficult for the patient and dental procedures difficult for the dentist.
- *Complication of Levodopa therapy*—due to Levodopa therapy, patient exhibits purposeless chewing, grinding and sucking movements that are quite bizarre. The patient may thrust or shake his tongue and chew or suck vigorously when there is nothing in mouth.

Diagnosis

- *Clinical diagnosis*—triad of tremor, rigidity and bradykinesia can be seen.

Management

- *Levodopa*—levodopa can cause dramatic reversal of symptoms of Parkinson's disease.
- *Anticholinergic drugs*—mild form of Parkinson's disease can be managed by anticholinergic drugs such as trihexyphenidyl, like benzotropine or ethopropazine.
- *Propranolol*—propranolol an adrenergic antagonist may be used to reduce tremors.
- *Bromocriptine*—bromocriptine is one of the newer drugs which are an agonist at the dopamine receptors.

Dental Considerations

- *Pretreatment sedation*—anxiety will increase both, tremor and degree of muscle rigidity. Pretreatment sedation with diazepam is often recommended, as it will reduce anxiety.
- *Precaution while changing posture*—when the dental treatment has finished, the patient should be warned to take care while changing from a supine to standing position, since levodopa has a significant orthostatic hypotensive effect.

Orofacial Dyskinesia

It is caused by extrapyramidal disorders, complication of phenothiazine therapy and dentures in gross malocclusion. It is more commonly occurs above 60 years.

It is characterized by severe involuntary, dystonic movements of the facial, oral and cervical musculature. Irregular and involuntary movements such as lip-smacking and lip-licking, protrusion of lips -as in pouting, protrusion of tongue and mandible with uncoordinated movements are mostly observed.

Correction of the denture occlusion may be effective therapy. Anti-Parkinsonism drugs therapy can be effective in some of the cases.

Granulomatous Disorders

Wegener's Granulomatosis

It is a disease of unknown etiology which basically involves the vascular, renal and respiratory systems. It is a granulomatous involvement of blood vessels resulting in necrosis of tissue. It is generally thought that the disease is aberrant hypersensitivity reaction to an unknown antigen.

Types (Clinical)

- *Generalized or classic Wegener's granulomatosis*—it involve upper respiratory tract, pulmonary and renal lesions.
- *Localized or limited Wegener's granulomatosis*—it affects oral and nasal cavity and the lungs.
- *Superficial Wegener's granulomatosis*—it exhibits lesion of skin and mucosa.

Clinical Features

- *Age and sex*—it usually occurs in 4th or 5th decade of life, with slight predilection for males.
- *Symptoms*—the most common symptom of Wegner's granulomatosis is nasal stuffiness with chronic discharge, which is sometimes bloody. Patient soon develops cough, hemoptysis, fever and joint pains. There is also presence of rhinitis, sinusitis and otitis or ocular symptoms. There are also non-specific symptoms of malaise, arthralgia and weight loss.
- *Signs*—hemorrhagic or vesicular skin lesions are also commonly present.
- *Renal symptoms*—glomerulonephritis, which develops ultimately to uremia and terminal renal failure.
- *Prognosis*—the disease is usually fatal, with mean survival time of 5 months. Death occurs due to involvement of kidney.

Oral Manifestations

- *Onset*—the disease usually starts with tumor like vegetations in mouth and nose (**Fig. 33-12**). Then inflammatory process starts in the interdental papilla, spreading rapidly in to the periodontium.
- *Ulceration*—ulceration can occur on any surface. Ulceration is usually perforating in nature.

Fig. 33-12: Vegetative growth with ulceration in the palate in case of Wegener's granulomatosis (Courtesy Dr Parate).

- *Strawberry gingivitis*—involvement of gingiva is the most common manifestation; which is characterized by ulceration, friable granular lesions or simple enlargement of gingiva. Inflamed, hyperplastic appearing and hemorrhagic gingiva may be found. *Strawberry gingivitis* is the term used for this type of gingiva.
- *Palate*—oral lesions typically include ulceration of the palate by extension of nose lesions and destruction of nasal septum. This will lead to perforation of palate.
- *Teeth*—there may be loosening of teeth with in some cases spontaneous exfoliation. After extraction of teeth patient is usually noticed poor healing.
- *Other features*—cranial nerve palsies, jaw claudication, labial mucosal nodule, oroantral fistulae, and parotid swelling.

Radiological Features

- *Alveolar bone*—there are often signs of alveolar bone loss.

Diagnosis

- *Clinical diagnosis*—typical strawberry gingivitis with necrotic ulceration in the oral cavity.
- *Laboratory diagnosis*—cytoplasmic localization is present with Wegener's granulomatosis. Histopathologically chronic inflammatory cells and multinucleated giant cells are found.

Differential Diagnosis

Agranulocytosis, leukemia, lymphoma—diagnosis by blood picture, possibly histology.

Management

- *Cotrimoxazole*—it is combination of *trimethoprim* and *sulfamethoxazole*. It has proved to be effective as an adjuvant or sole therapy in both localized and generalized forms.
- *Corticosteroids*—regimen of cyclophosphamide 12 mg/kg body weight/day with prednisolone 1 mg/kg body weight have been utilized to obtain complete remission.
- *Others*—other treatment modalities includes cyclosporine, intravenous pooled immunoglobulin, and local irradiation.

Sarcoidosis

It is also called as *Boeck's sarcoid*, *Besnier-Boeck-Schaumann disease*. It is a disease of unknown etiology. It is a multi-system granulomatous disease. It is characterized by depression of delayed type of hypersensitivity, suggesting an impaired cell-mediated immunity and raised or abnormal serum immunoglobulin, suggesting lymphoproliferation.

Clinical Features

- *Age, sex and race distribution*—it commonly affects young adults with female predilection. It shows more prevalence in blacks.
- *Site*—lesions are most common in lungs, skin, lymph nodes, salivary glands, spleen and bones.
- *Symptoms*—mild malaise, fever, weight loss, fatigue and cough can be the chief features of the disease.
- *Signs*—there is presence of bilateral hilar lymphadenopathy, and pulmonary infiltration.
- *Lupus pernio*—these are the cutaneous lesions which appear as multiple, raised red violaceous patches. It occurs in group, grows slowly and does not ulcerate or crust.
- *Erythema nodosum*—it is nonspecific tender erythematous nodule seen on lower leg.
- *Eye lesion*—it includes anterior uveitis. In case of involvement of lacrimal gland patient may suffer from keratoconjunctivitis sicca.
- *Lofgren's syndrome*—it consist of erythema nodosum, bilateral hilar lymphadenopathy and arthralgia.

Oral Manifestations

- *Site*—it is rare in oral cavity, but cases are reported on salivary gland, lip, palate and buccal mucosa.
- *Salivary gland involvement*—it will lead to enlargement of salivary gland. This enlargement will lead to xerostomia patient. Due to xerostomia there is increased incidence of dental caries and ulceration of buccal mucosa.
- *Lip*—it appears as small papular nodules or plaques or resembles herpetic lesions or fever blisters.
- *Palate and buccal mucosa*—on the palate and buccal mucosa, it is described as bleb like, containing a clear yellowish fluid or as solid nodules.
- *Heerfordt's syndrome*—it consists of parotid enlargement, anterior uveitis, facial paralysis and fever.

Radiological Features

- *Jaw bone*—there is ill-defined radiolucencies which eroded the cortex. Expansion is absent in this case.
- *Chest radiograph*—radiological changes in lungs are of paramount importance. Based on chest radiograph, four stages of sarcoidosis can be distinguish:
 - *Stage 0*—characterized by a normal radiograph of the thorax.
 - *Stage 1*—bilateral enlargement of the hilar nodes, without pathologic changes in the lung fields. It represents an early stage of the disease.
 - *Stage 2*—bilateral enlargement of the hilar lymph nodes with pathologic changes in the lung fields around the hili.

- *Stage 3*—no enlargement of the lymph nodes, but extended and sometimes patchy or striped changes in both lung fields. The patches may be confluent and bullae may be formed.

Diagnosis

- *Clinical diagnosis*—salivary gland involvement with lymph nodes involvement with non-specific ulcer in the oral cavity, aids in clinical diagnosis.
- *Kveim-Siltzbach test*—is an intracutaneous test for the diagnosis of sarcoidosis—Kveim-Siltzbach test is positive in some cases. In this test, intradermal injection of a saline suspension of known human sarcoid tissue used as an antigen is given to a patient suspected to have sarcoidosis. One month after the injection, any palpable nodule is excised and examined histologically for evidence of a sarcoid reaction, or epithelial tubercle.
- *Laboratory diagnosis*—there is increased serum angiotensin converting level. Histopathologically *asteroid bodies* and *Schumann's bodies* are found.

Management

- *Corticosteroid*—asymptomatic patient requires no treatment as the lesion may resolve in 2 years of duration. In patient with symptoms corticosteroids can be given.
- *Refractory (does not respond to treatment) sarcoidosis*—in this case methotrexate, azathioprine, chlorambucil and cyclophosphamide is used.

Midline Lethal Granuloma

It is also called as *malignant granuloma*, *midline lethal granulomatous ulceration* and *midline nonhealing granuloma*. It is described as idiopathic progressive destruction of nose, palate, face and pharynx. Midline lethal granuloma is also associated with T cell lympho-proliferative disorders.

Etiology

- *Immune mechanism*—Lethal granuloma is due to a dysfunction of the immune mechanism normally responsible for granuloma formation.
- *Hypersensitive response*—Nowadays, it represents a fulminant hypersensitivity response to an unidentified antigen.
- *Vascular allergy*—vascular allergy like arthus phenomenon or periarteritis nodosa.

Clinical Features

- *Age*—it is more commonly seen in adults.
- *Site*—commonly involved sites are nose, palate, face and pharynx.

- **Onset**—it begins as superficial ulceration of the palate or nasal septum, often preceded by a feeling of stuffiness in the nose. This may persist for a month or two to several years. Pain may be present.
- **Progress**—eventually ulceration spreads from the palate to the inside of the nose and then to the outside.
- **Signs**—the palatal, nasal and malar bones may become involved, undergo necrosis and eventually sequester. Destruction is a prominent feature and loss of entire palate is common (**Fig. 33-13**). The patient may exhibit purulent discharge from the eyes and nose; perforating sinus tracts may develop and soft tissues of face may slough away leaving a direct opening into the nasopharynx and oral cavity.
- **Prognosis**—the patient ultimately dies of exhaustion or of hemorrhage if a large blood vessel is eroded. Death can also occur due to localized destruction of tissue in the midline of face.

Fig. 33-13: Destruction of palate seen in midline (Courtesy Dr Chole).

Diagnosis

- **Clinical diagnose**—destructive lesion in the midline of palate will diagnose this condition.
- **Laboratory diagnosis**—biopsy shows extensive necrosis with infiltration of some inflammatory cells and formation of occasional new capillaries.

Differential Diagnosis

- **Wegener's granulomatous**—in it there is presence of lung and renal diseases.
- **Noma**—in midline, lethal granuloma location is typical.

Management

- **Corticosteroids**—corticosteroid therapy has proven beneficial in some cases.
- **Radiation therapy**—radiation therapy of 5000 rad appears to be a treatment modality, in which remission of over 15 years is reported.

Chronic Granulomatous Disease

It is an uncommon hereditary disease with X-linked mode of transmission. It is characterized by severe recurrent infections as a result of defect of intracellular leukocytes enzymatic function, with decreased oxidative metabolism, in which there is failure to destroy certain catalase-positive microorganisms, including staphylococci.

Clinical Features

- **Age and sex**—majority of the patient are males, but females are also commonly affected. It is commonly found in children and infants.
- **Site**—there is widespread infection from infancy; usually affecting lymph nodes, lung, liver, spleen, bone and skin.
- **Skin lesion**—skin lesions occur on face, leading to tissue necrosis and granuloma formation.
- **Signs**—abscess, septicemia, pneumonia, pericarditis, meningitis and osteomyelitis are common features.

Oral Manifestations

- **Appearance**—granulomatous lesions of the oral and oropharyngeal mucosa usually present as sessile, lobulated, moderately firm and relatively nontender nodules and papules with normal coloration and with little or no surrounding inflammatory mucosal erythema.
- **Ulcerative lesion**—with time, some of the granulomas may ulcerate centrally and present as a deep, painless ulcer with a nonerythematous rolled border, reminiscent of squamous cell carcinoma.
- **Other features**—there is diffuse stomatitis, and benign migratory glossitis is also present.

Diagnosis

- **Clinical diagnosis**—granulomatous sessile lesion will give clue to diagnosis.
- **Laboratory diagnosis**—it is established by neutrophils function test.

Management

- **Conservative surgical excision**—localized lesions without systemic connection can be treated by conservative surgical removal and plastic surgical reconstruction.

- **Medication**—intralesional and systemic corticosteroids, low-dose radiotherapy, methotrexate, dapsone, salazosulfapyridine (sulfasalazine), hydroxychloroquine sulfate, among others. No therapy has proven to be universally effective in orofacial granulomatosis without systemic involvement.

Collagen Disorders

Scleroderma

It is also called as *systemic sclerosis*, or *Hidebound disease*. It is rare collagen disorder, which is characterized by hardening and tightening of the skin that can manifest as either localized or systemic form. It is a disease which involves connective tissue, blood vessels and lead to fibrosis. It is also called as progressive systemic sclerosis. Name is derived from sclero—hard derma—skin.

Types

- **Systemic or progressive systemic sclerosis**—it is diffuse and involves both skin and internal organ.
- **Localized form**—it involve the underlying muscle and bone along with skin and subcutaneous tissue. It is of two types:
 - **Morphea**—it is circumscribed form and is characterized by local changes limited to skin
 - **Linear**—it affects face, scalp and frontoparietal region.

Etiology

- **An endocrine dysfunction**—in some cases of endocrine dysfunction mainly thyroid and parathyroid disturbances can cause scleroderma.
- **Vascular disease**—basically an endarteritis obliterans, resulting in decreased vascular supply.
- **Nervous disorder**—since skin lesion often follows the distribution of nerves, nervous disorder may be causative factor.
- **Toxic or infectious agents**—shock or pneumonia, influenza, diphtheria and exanthematous disease.
- **Allergic reaction**—an antigen-antibody type of reaction is observed in scleroderma.
- **Environmental factors**—such as exposure to silica dust, vinyl chloride, benzene and tryptophan.

Clinical Features

Progressive systemic sclerosis

- **Age and sex**—it generally begins in childhood or young adult and greatest incidence is between 30 and 50 years of age. Females are more commonly affected with a ratio of 3:1.
- **Site**—it usually begins on face, hand or trunk.

- **Symptoms**—there is development of indurated edema of skin, neuralgia and paresthesia.
- **Signs**—Initial sign of PSS is frequently Raynaud's phenomenon, a paroxysm vasospasm of finger. In several months the edema is replaced by tightening and hardening of the skin, which results in difficulty in movements of the affected parts.
- **Involvement of internal organs**—hyperpigmentation, telangiectases and subcutaneous calcification may occur, leading to deformity and severe cosmetic problems along with involvement of internal organs.
- **Acro-steolysis**—resorption of terminal phalanges is also occur in scleroderma. Finger may also become clawlike.
- **Skin involvement**—skin area has thickened, hidebound cavity with lack of mobility of skin, limited mouth opening and renal involvement.
- **Syndrome associated**—it can be associated with progressive hemifacial atrophy (Parry-Romberg syndrome).

Localized form (circumscribed or morphea)

- **Site**—it usually occurs on the sides of the chest and thighs. They may be present for several months to many years.
- **Onset and progress**—it begins with violaceous patches on the skin. These lesions enlarge; become indurated and eventually loose hair and ability to sweat.
- **Hidebound character**—due to thickening patient assumes hidebound (constricted) character.
- **Signs**—progressively, these lesions turn into hypo or hyperpigmented areas depressed below the level of the skin. They may become stiff and hard. Affected skin appears rigid, inelastic, atrophic and shiny.

Localized form (linear)

- **Appearance**—a linear form of disease develops as a thin band of sclerosis that may run the entire length of extremities involving underlying muscle, bones and joints.
- **En coup de sabre**—a band made up of furrow with an elevated ridge on one side is often termed as 'coup de sabre' since it resembles the mark produced by the blow of saber (curved sword).

Oral Manifestations

- **Site**—the tongue, soft palate, lips and larynx are commonly involved.
- **Appearance**—these are characterized by mild edema, which is followed by atrophy and induration of mucosal and muscular tissue.
- **Mask like facies**—involvement of facial skin results in characteristic smooth, taut and masklike facies.
- **Mouse facies**—nasal alae may become atrophied resulting in pinched appearance to the nose resulting in mouse species.

- *Lips*—the lips become thin, rigid and partially fixed, producing microstomia.
- *Microstomia*—the oral aperture narrows considerably. Skin folds are lost around the mouth.
- *Tobacco pouch mouth or purse string appearance*—it can be seen periorally where furrow rows radiate from the atrophic vermilion borders, creating the so-called *tobacco pouch mouth or purse string appearance*.
- *Tongue*—tongue can become hard and rigid, losing its mobility and papillary pattern, making speaking and swallowing difficult. The color of tongue changes to a livid appearance. In the end stages, the tongue lays as a stiff, reduced body in the floor of mouth.
- *Lingual frenum*—the lingual frenum, which usually reflects the first oral change, shortens, becomes tendinous and finally disappears.
- *Neuropathy*—resorption of mandible may lead to pressure of the inferior alveolar nerve. This will result in neuropathy.
- *Dysphasia*—involvement of esophagus causes dysphagia.
- *Temporomandibular joint*—involvement of soft tissues around the TMJ leads to restricted movement of mandible, causing a pseudoankylosis.
- *Mandible*—when the facial tissues and muscles of mastication are involved the pressure exerted will cause resorption of mandible at the attachment of masseter muscle.
- *Salivary hypofunction*—in some cases salivary hypofunction can also be present.
- *Gingiva*—gingival hyperplasia may result from calcium channel blocker.

Radiographic Features

- *Periodontal ligament*—extreme widening of the periodontal ligament, two to four times the normal thickness, which is more prominent around posterior teeth with intact lamina dura. The periodontal changes are the direct result of changes within the membrane due to the underlying disease.
- *Margins*—borders of the lesions are smooth and sharply defined.
- *Bone resorption*—bone resorption occurs usually at the angle of mandible. It is bilateral and symmetrical.
- *Condylar involvement*—partial or complete resorption of condyle and coronoid process of the mandible, as a result of abnormal muscle pull or pressure from soft tissues is reported.

Diagnosis

- *Clinical diagnosis*—claw like finger, ulceration in finger, Raynaud's phenomenon, shiny skin, tobacco pouch mouth are typical features of this disease.

- *Radiological features*—periodontal ligament widening with resorption of bone at angle of mandible.
- *Laboratory diagnosis*—anticentromere antibodies or anti-Scl 70 are detected.

Management

- *D-penicillamine*—a drug has shown promise in the management by decreasing both, the skin thickening and organ involvement by interference with cross-linking of collagen and immunosuppression.
- *Extracorporeal photochemotherapy*—it is beneficial in skin lesion.
- *Other therapy*—other therapy like angiotensin converting enzyme inhibitor and calcium channel blocking agents may control hypertension in the patient.
- *Dental management*—the mouth opening may be increased by use of stretching exercises. Effective treatment of it is to use an increasing number of tongue blades between posterior teeth. If this is insufficient, bilateral removal of commissure may be necessary. Patient with extensive resorption of the angle of mandible is at risk of fracture and should therefore avoid trauma.

Kawasaki Disease

Kawasaki disease, or mucocutaneous lymph node syndrome, is a vasculitis that affects medium and large arteries with a corresponding cutaneous lymph node syndrome.

Clinical Features

- *Age*—it most commonly occurs in children between 3 months and 12 years of age.
- *Symptoms*—patients present acutely with edema, erythema of the hands and feet, fever and rash. The associated temperature must exceed 38.5°C (101.3°F) for 5 days to meet diagnostic criteria.
- *Signs*—bilateral congestion of ocular conjunctiva, indurative edema, erythema of palms, soles and membranous desquamation of fingers and toes. There is also polymorphous exanthema of torso without vesicles or crusts.
- *Lymphadenopathy*—acute nonpurulent swelling of cervical lymph nodes.
- *Cardiac sequelae*—cardiac sequelae to the vasculitis may result in aneurysm and myocardial infarction. Myocarditis commonly occurs within a week after the fever. Within 2-3 weeks, the previously edematous palms and soles peel and slough.

Oral Manifestations

- *Strawberry tongue*—strawberry like reddening and swelling of tongue papillae and diffuse reddening of

oral and pharyngeal mucosa, sometimes with gingival ulceration.

- *Lip*—the labia are cracked, cherry red, swollen, and hemorrhagic. The last of these may be due to the long-standing high-grade fever.
- *Facial palsy*—it is also some time seen in Kawasaki disease.

Diagnosis

- *Clinical diagnosis*—for diagnosis, 4 of the 5 following criteria must also be met: (1) peripheral extremity edema, erythema, or desquamation; (2) polymorphous exanthem; (3) bilateral conjunctival injection; (4) erythema and strawberry tongue in the oral cavity; and (5) acute cervical adenopathy.
- *Laboratory diagnosis*—there is proteinuria, leukocytosis, increased sedimentation rate and positive C-reactive protein.

Management

- *Intravenous gammaglobulin*—it is the most effective treatment in case of Kawasaki's disease.
- *Other drugs*—aspirin or systemic steroids can also be given in some cases.

Skin Disorders

Pityriasis Rosea

It is an acute skin eruption of unknown etiology.

Clinical Features

- *Age and sex*—it is more common in spring and autumn and it involves young adults chiefly, with no sex predilection.
- *Symptoms*—the lesion often manifests mild headache and low grade fever and cervical lymphadenopathy.
- *Primary lesions*—the generalized outbreak is frequently preceded by the appearance of a 'primary lesion' or 'herald spot' seven to ten days previously.
- *Appearance*—it is characterized by the appearance of superficial, light red macules or papules, generalized over most of the skin surface (**Fig. 33-14**).
- *Size*—the spot is bright-red and larger (3 to 4 cm in diameter) than the multiple eruptions which follow its appearance.
- *Shape*—the individual exanthematous lesion is commonly ovoid, with long axis parallel to the natural lines of cleavage of skin and are covered by a thin silvery scales.

Fig. 33-14: Superficial red macule seen over the skin in case of Pityriasis rosea (Courtesy Dr Pincha).

Oral Manifestations

- *Incidence*—the oral lesion occurs either concomitantly with, or subsequent to the skin manifestations.
- *Site*—it can occur on buccal mucosa, although tongue and palatal lesions have been reported.
- *Appearance*—oral lesion appears as erythematous macule, with or without central area of grayish desquamation.
- *Size and margins*—the lesion may be single or multiple, irregular in shape, occasionally showing raised borders and vary in size from few mm to 1-2 cm in diameter.

Diagnosis

- *Clinical diagnosis*—herald spot on the skin will give clue to diagnosis.
- *Laboratory diagnosis*—biopsy shows acanthosis and focal parakeratosis with microvesiculation or simply sprinkling of leukocytes within the epithelium.

Management

It requires no treatment since the disease is self limiting and generally undergoes rapid spontaneous regression.

Incontinentia Pigmenti

It is also called as *Bloch-Sulzberger syndrome*. It is transmitted as sex-linked dominant trait.

Clinical Features

- *Age and sex*—it appears shortly after birth and exclusively seen in females.
- *Appearance*—it is characterized by the appearance of erythematous and vesiculobullous lesions on the trunk and extremities which frequently disappear and

reappear. Then, they are gradually replaced by white keratotic, lichenoid, papillary or verrucous lesions, which then persist for some months.

- *Infant lesion*—some of the lesions in infants are brownish gray macules in a streaked, patchy distribution over the trunk and extremities, occurring subsequent to the verrucous keratotic lesions.
- *Melanin pigmentation*—there is heavy melanin pigmentation of epithelium, dropping down into cluster of chromatophores in the upper dermis (incontinence), which gives the disease its name.
- *Associated defect*—other defects can be seen like cataract, optic atrophy, strabismus, retrolental fibroplasia, central nervous system involvement and lesions of skeletal system.

Clinical Staging

- *Vesicular stage*—vesiculobullous lesion seen in trunk and limbs. Resolution within 4 months.
- *Verrucous stage*—verrucous cutaneous plaques develop. Resolution by 6 months.
- *Hyperpigmentation stage*—brown skin lesion with swirling (twisting) pattern.
- *Atrophy and depigmentation stage*—atrophy and depigmentation of skin can occur (Fig. 33-15).

Oral Manifestations

- *Site*—both the deciduous and permanent dentitions may be affected.
- *Teeth*—there is delayed tooth eruption, peg and cone shaped crowns, congenitally missing teeth, malformed teeth and additional cusps.

Fig. 33-15: Depigmented lesion seen on leg of patient in Incontinentia pigmenti (Courtesy Dr Pincha).

Diagnosis

- *Clinical diagnosis*—depigmented or vesicular lesion on trunk with cone shaped crown may suspect this disease.
- *Laboratory diagnosis*—biopsy shows intraepithelial clefts filled with eosinophils. It may show melanin containing macrophages.

Management

Dental management—dental defects can be corrected with the assistance of orthodontics and prosthetic dentistry.

Acanthosis Nigricans

It is acquired dermatological disorders characterized by velvety brownish discoloration of the skin.

Types

- *Benign*—it may be present at birth or occur later in childhood; appears to be genetic in origin inherited as a dominant characteristic.
- *Malignant*—it is associated with internal malignancy like adenocarcinoma of stomach and occurs in older age group.
- *Pseudoacanthosis nigricans*—it is most common and is associated with endocrinopathy.

Clinical Features

- *Site*—the most common areas involved are axilla, palms and soles and face and neck.
- *Appearance*—skin lesions are symmetric with mild hyperpigmentation and mild papillary hypertrophy of only small patchy areas. In some cases, it is heavily pigmented, aggressively verrucous lesion involving much of the skin.
- *Symptoms*—the verrucous lesions are often pigmented and generalized pruritis is also a common finding.

Oral Manifestations

- *Site*—the tongue and lips are most commonly involved, followed by buccal mucosa.
- *Incidence*—oral manifestations are most common with malignant form.
- *Tongue*—there is hypertrophy of the filiform papillae producing a shaggy, papillomatous surface on the dorsal tongue.
- *Lips*—the lips may be enlarged and covered by papillomatous growths, particularly at the angle of mouth.
- *Buccal mucosa*—the buccal mucosa may show a velvety white appearance with occasional papillary lesion.

- *Gingival hyperplasia*—gingival hyperplasia may also occur. Interdental gingiva may become so hyperplastic that it interferes with eating as it covers the teeth.

Diagnosis

- *Clinical diagnosis*—brownish alteration of skin velvety white appearance of buccal mucosa may be diagnostic features of scleroderma.
- *Laboratory diagnosis*—there is marked acanthosis, coupled with peculiar parakeratosis.

Management

Keratolytic lesion—this may improve appearance of benign form.

Ehlers-Danlos Syndrome

It is also called as *cutis hyperelastica* and it is a group of hereditary disorders of connective tissue. There is production of abnormal collagen, resulting in selective defect in collagen synthesis.

Clinical Features

- *Hyperelasticity*—there is hyperelasticity of skin, hyperextensibility of the joints and fragility of skin and blood vessels, resulting in excessive bruising as well as defective healing of skin wounds.
- *Rupture of large arteries*—rupture of large arteries as well as of intestine often occurs, producing a life threatening situation.
- *Rubber man*—in some patients, skin extensibility is pronounced, so that he can stretch the skin significantly. It is called as 'rubber man'.
- *Signs*—hypertelorism, a wide nasal bridge, epicanthic folds, protruding ears and frontal bossing are often present.
- *Subcutaneous nodules*—freely movable subcutaneous nodules are frequently found, which represent fibrosed lobules of fat.
- *Papyraceous scarring*—the scarring of skin following wound healing in these patients is unusual, as the scars tend to spread rather than contract in time. It resembles crumpled cigarette paper.

Oral Manifestations

- *Oral mucosa*—oral mucosa is of normal color but is excessively fragile and bruises easily.
- *Gingiva*—the gingival tissue appears fragile and bleeds after toothbrushing.
- *Gorlin sign*—it is positive in this patient. Patient can touch its nose with the tip of tongue.

- *Temporomandibular joint*—hypermobility of temporomandibular joint resulting in repeated dislocations of the jaw have been reported.
- *Teeth*—there may be lack of normal scalloping of the dentinoenamel junction, formation of irregular dentin and increased tendency to form pulp stones with hypoplastic changes in enamel.

Diagnosis

- *Clinical diagnosis*—hyperelasticity, hyperextensibility of joint and Gorlin's sign can give clue to diagnosis.
- *Laboratory diagnosis*—clotting time is normal, but capillary fragility test is usually positive.

Management

Not specific—there is no specific treatment for this disease, but surgical procedures should be carried out carefully as healing problems can exist.

Tuberous Sclerosis

It is also called as *Epiloia-Bourneville syndrome*. It is inherited as autosomal dominant trait.

Clinical Features

- *Facial angiofibroma*—it is also called as adenoma sebaceum. These are smooth surface papules (**Fig. 33-16**) which occur on nasolabial fold. Some lesions are also found under margins of nails.
- *Shagreen patches*—these are seen on skin and they resemble sharkskin-derived shagreen cloth.
- *Ash-leaf spots*—it appear on cutaneous surface.
- *CNS features*—it includes seizure, mental retardation. Potato like growth (tuber) can be seen at autopsy in CNS.
- *Cardiac rhabdomyoma*—it is tumor of heart. Myocardial function may hamper due to this tumor.

Fig. 33-16: Multiple papular facial lesions seen on face in case of tuberous sclerosis (Courtesy Dr Pincha).

- *Angiomyolipoma*—it can also occur in this syndrome and it is vascular smooth muscle adipose tissue tumor.

Oral Manifestations

- *Enamel defect*—there is developmental pitting defect on facial aspect of permanent dentition.
- *Fibrous papule*—it can also be present in this syndrome. These are most commonly occur in anterior gingival mucosa. In some cases diffuse gingival enlargement can also occur.

Diagnosis

- *Clinical diagnosis*—presence of facial angiofibroma, shagreen patch, mental retardation, and cardiac angiolipoma may diagnosis this disease. Gingival fibroma and enamel pit can also occur.
- *Laboratory diagnosis*—biopsy shows nonspecific fibrous hyperplasia in gingival fibroma.

Management

- *Anticonvulsant agents*—these are given to manage seizure.
- *Maintenance of oral hygiene*—as phenytoin is given in these cases, maintenance of oral hygiene is very important.

Seborrheic Keratosis

It is skin lesion which is characterized by benign proliferation of epidermal basal cells.

Clinical Features

- *Age*—it is common in older age group and seen in fourth decade of life.
- *Site*—it is seen on face, trunk, and extremities.
- *Appearance*—these are multiple, small tan to brown macule which enlarge gradually. They appear as stuck onto the skin.
- *Surface*—surface of lesion is fissured, pitted and verrucous.
- *Size*—size is less than 2 cm in diameter.
- *Dermatosis papulosa nigra*—it is seen in black people and is characterized by multiple, small dark brown papule scattered in zygomatic and periorbital region.
- *Leser-Trelat sign*—sudden appearance of seborrheic keratosis with pruritis has been associated with internal malignancy. This is called as Laser-Trelat sign.

Diagnosis

- *Clinical diagnosis*—small brown papular lesion seen on face and trunk will diagnose this condition.
- *Laboratory diagnosis*—there is exophytic proliferation of basilar epithelial cells with surface keratinization, acanthosis and papillomatosis.

Management

- *Cryotherapy*—cryotherapy with liquid nitrogen is used to remove the lesion.

Sebaceous Hyperplasia

It is localized proliferation of sebaceous gland of skin.

Clinical Features

- *Age*—it is common in older age group and seen in fourth decade of life.
- *Site*—it is seen most commonly on facial skin in the region of cheeks and forehead.
- *Symptoms*—it is usually painless.
- *Signs*—it is soft, nontender with yellow and white discoloration. There is small central depression which represents area where duct of sebaceous gland terminated.
- *Compression test*—after compression of lesion sebum (thick yellow product) is expressed from sebaceous gland.

Diagnosis

- *Clinical diagnosis*—compression test showing sebum from the lesion.
- *Laboratory diagnosis*—biopsy shows collection of enlarged sebaceous gland around the centrally located sebaceous ducts.

Management

- *Excisional biopsy*—this is done to differentiate it with basal cell carcinoma.

Actinic Lentigo

Lesion which occurs due to ultraviolet light damage to skin. It is also called as *lentigo solaris*, *solar lentigo*, *age spot*, *liver spot* and *senile lentigo*.

Clinical Features

- *Age*—it is common in older age group, in the age group of 40 to 70 years.
- *Site*—it is common on dorsal surface of hand, face and arms. Commonly seen in white people.
- *Appearance*—it is multiple with individual lesion appear as uniformly pigmented brown to tan macule with well demarcated and irregular border.
- *Size*—size is less than 5 mm.

Diagnosis

- *Clinical diagnosis*—brown to tan pigmented macule on face may give clue to diagnosis

- *Laboratory diagnosis*—elongated and club-shaped rete pegs are present.

Management

- *Topical retinoic acid*—this can reduce the color intensity of lesion.
- *Laser*—Q shaped ruby laser can be use for the treatment of this lesion.

Melasma

It is symmetric hyperpigmentation of sun exposed skin, face and neck. This is usually associated with pregnancy so it is also called as mask of pregnancy.

Clinical Features

- *Age*—it is seen in adult women.
- *Site*—it is seen in midface, forehead, upper lip, and chin.
- *Appearance*—it is bilateral, light to dark brown cutaneous macule. Pigmentation may darken with time.
- *Size*—size range from few millimeter to 2 cm in diameter.

Diagnosis

- *Clinical diagnosis*—bilateral symmetric pigmentation in pregnancy patient will diagnose this condition
- *Laboratory diagnosis*—there is increase melanin deposition in epidermis.

Management

- *Three percent hydroquinone and tretinoin*—it is effective in many cases.

Xeroderma Pigmentosum

It is genodermatoses in which multiple cutaneous malignancies develop. It is inherited as autosomal recessive trait and caused by defect in the excision repair mechanism of DNA.

Clinical Features

- *Age*—it occurs in early age group.
- *Symptoms*—there is increased tendency to sunburn. Patient also notices freckled pigmentation and patchy depigmentation of skin. Patient also notices neurological manifestation like below normal intelligence.
- *Actinic keratosis*—it is evident in early age group. These lesions will change into basal cell carcinoma or squamous cell carcinoma.
- *Oral features*—squamous cell carcinoma develops on lower lip and tongue.

Diagnosis

- *Clinical diagnosis*—skin cancer in young individual will give strong clue to diagnosis of Xeroderma pigmentosum.
- *Laboratory diagnosis*—biopsy shows features of cutaneous malignancies.

Management

- *Topical chemotherapeutic agents*—topical chemotherapeutic agent's 5-fluorouracil is used to treat actinic keratosis.
- *Genetic counseling*—it should be done before marriage.
- *Prevention*—patient is ask to avoid sun exposure, wear protective clothing

Muscle Disorders

Muscular Dystrophy

It is genetically determined disease characterized by degeneration of muscle leading to progressive weakness.

Types

- *Severe generalized familial muscular dystrophy*—it is described as a rapidly progressive muscle disease, usually beginning in early childhood and presenting a strong familial transmission.
- *Mild restricted muscular dystrophy*—it is a slowly progressive proximal myopathy which primarily involves the muscles of shoulder and face and has a weak familial incidence. It is transmitted as an autosomal dominant trait.

Clinical Features

- *Age and sex*—it predominately affects males. It begins in childhood, usually before the age of 6 years and rarely after 15 years.
- *Symptoms*—the earliest symptom is inability to walk or run due to which, the children fall readily and is associated with muscular enlargement and weakness. In case of mild restricted dystrophy, patient is unable to raise arms above the head and inability to close eyes.
- *Waddling gait*—the muscular enlargement ultimately proceeds to atrophy and the limbs appear flaccid. It is the atrophy which is responsible for the postural and ambulatory defects, such as *waddling gait*.
- *Signs*—scapular muscles become atrophic and weak with subsequent alteration in the posture.
- *Cardiac abnormalities*—cardiac abnormalities including cardiomegaly and tachycardia are often present and many patients die of sudden cardiac failure.

Oral Manifestations

- *Location*—the muscles of mastication, facial ocular, laryngeal and the pharyngeal muscles are usually involved, only in the late course of disease.
- *Teeth*—due to lack of muscle tension, teeth cannot be kept properly aligned in the arch.
- *Tapir-lips*—the lips develop a characteristic looseness and protrusion, which have been described as ‘tapir-lips’. The patient is unable to whistle or smile.
- *Open bite and diastema*—there may be severe open bite and development of diastema.
- *Temporomandibular joint*—locking and clicking of the jaw.

Diagnosis

- *Clinical diagnosis*—there is muscular weakness, waddling gait, tapir-lip will give clue to diagnosis.
- *Laboratory diagnosis*—there is gradual disappearance of muscle fibers, as the disease progresses no fibers may be recognized. Serum creatinine phosphokinase levels are elevated in all males.

Management

There is no treatment for this disease. Physical therapy may help prolong the use of specific muscle group.

Myotonias

Myotonias are the disorders characterized by abnormally slow relaxation after muscle contraction.

Types

- *Dystrophic myotonia*—it is also called as *myotonic dystrophy* or *dystrophic myotonia*. It is inherited as an autosomal dominant trait.
- *Myotonia congenita (Thomsen’s disease)*—it is transmitted as an autosomal dominant trait with incomplete penetrance in some families. It is generalized myotonia without weakness.
- *Myotonia congenita (Becker type)*—it appears late in childhood and characterized by muscle hypertrophy.

Clinical Features

- *Location*—atrophy of the muscles is seen usually in the hands and forearms. It can be seen in muscles of face, jaws, neck and levator of eyelids.
- *Symptoms*—there is associated weakness of the muscles. Muscular contraction induces a severe, painless muscular spasm, and an actually delay in relaxation.
- *Facial muscle*—alteration in the facial muscles, which consist of ptosis of the eyelids and atrophy of the masseter and sternocleidomastoid muscles.

- *Myopathic facies and swan neck*—the masseteric atrophy produces narrowing of the lower half of the face which, with ptosis and generalized weakness of the facial musculature gives the patient a characteristic ‘myopathic facies’ and ‘swan neck’.
- *Percussion contraction*—electrical and physical stimulation of a muscle produces the characteristic prolonged contraction or ‘percussion contraction’.
- *Dysphagia*—pharyngeal and laryngeal myotonia also exhibit weakness manifested by a weak, monotonous nasal type of voice and subsequent dysphagia.
- *TMJ*—recurrent dislocations of the jaw is also reported in this disease.
- *Eye*—blinking with strong closure of the eyes will sometimes produce a prolonged contraction of the lids.
- *Other*—other features are testicular atrophy, cataract, hypothyroidism with cold extremities, slow pulse, loss of hair and functional cardiac changes.

Diagnosis

- *Clinical diagnosis*—swan neck, muscular weakness, myopathic facies and atrophy of muscles of mastication.
- *Laboratory diagnosis*—there is enlargement of scattered muscle fibers and the presence of centrally placed muscle nuclei in long rows. True hypertrophy in some fibers, is found, as well as in isolated fibers which show extreme degenerative changes including nuclear proliferation, intense basophilic cytoplasmic staining and phagocytosis.

Management

There is no specific treatment for this disease.

Hemifacial Spasm

It is a disease characterized by a repeated, rapid, painless, irregular, nonrhythmic, uncontrollable, unilateral contraction of the facial muscles. It may occur due to compression of the facial nerve, in the facial canal, adjacent to the stylomastoid foramen.

Clinical Features

- *Location*—it usually begins in the periorbital muscles, but soon spreads to the entire half of the face.
- *Precipitating factors*—these spasms are often triggered by fatigue, tension or facial activity and are of brief duration, usually lasting for only a few seconds.
- *Symptoms*—it is first manifested as a brief transitory twitching, but may progress to sustain a spasm.
- *Signs*—in cases of long standing hemifacial spasms, mild facial contracture may occur with lid closure and lip pursing.

Diagnosis

- *Clinical diagnosis*—muscular spasms which is triggered by fatigue and twitching.

Management

- *Decompression of the nerve*—decompression of the nerve in its canal has offered relief in some cases. Prognosis is good, remission and recurrence may occur over a period of years.

Paramyotonia

It is a nonprogressive myotonia, inherited as an autosomal dominant characteristic that is not associated with muscular wasting. Characteristically, the cramping attacks are precipitated on exposure to cold.

Clinical Features

- *Symptoms*—it is manifested by cramping, stiffness and weakness of the muscles of the face and neck, fingers and hands, upon exposure to cold. Muscles cramping may disappear within an hour; the weakness may persist for several days.
- *Mask-like appearance*—the eyelids are closed and the face assumes a *mask-like* appearance.
- *Tongue*—the tongue may exhibit a similar cramping after drinking cold liquids and the speech becomes blurred. In many cases, myotonia of the tongue may be induced by percussion.

Diagnosis

- *Clinical diagnosis*—masklike appearance seen in face. Muscle cramping will disappear within hour after exposure to cold.

Management

There is no specific treatment for it, but the prognosis is excellent with frequent improvement during adult life.

Myasthenia Gravis

It is an autoimmune chronic disease characterized by progressive weakness of the skeletal muscles, particularly those innervated by the cranial nerves. It is characterized by easy fatigability of the striated muscles secondary to disorders at the neuromuscular junction. It affects acetylcholine receptors of muscle fibers resulting in fatigability of skeletal muscle.

Etiology

- *Defective neuromuscular transmission*—there is a defect in the neuromuscular transmission, which occurs due to

coating of acetylcholine receptors by circulating antibodies. This will result in the fault acetylcholine mechanism.

- *Hyperplasia of thymus*—it may occur in the endocrine system due to thymus hyperplasia or tumors of the thymus.
- *Other factors*—it may be related to pregnancy, menstruation and hyperthyroidism.

Clinical Features

- *Age and sex*—it occurs in adults in the middle age group with a predilection for women.
- *Symptoms*—there is rapidly developing weakness in voluntary muscles, following even minute activities. Patient may suffer from diplopia (double vision) and ptosis (drooping eyelids) and extraocular muscular paresis (an inability to focus the eyes) and dysarthria (slurring of word).
- *Sorrowful appearance of face*—there is dropping of the face, leads to sorrowful appearance of the patient.
- *Signs*—the neck muscles may be so weak that the head can not be held up without support.
- *Progress*—patients become exhausted, loses weight becomes further weakened and may eventually become bedridden. Death frequently occurs from respiratory failure.

Oral Manifestations

- *Symptoms*—the patient's chief complaints may be difficulty in mastication, deglutition and dropping of the jaw. Speech is often slow and slurred and disturbance in taste sensation occurs. Dysphagia and regurgitation of food are common.
- *Tongue*—there may be weakness of the tongue and palatal muscles. Protrusive movements of the tongue may become weak leading, at times to posterior collapse of the organ with airway obstruction.

Diagnosis

- *Clinical diagnosis*—ptosis, diplopia, dysphagia, sorrowful appearance of face.
- *Laboratory diagnosis*—elevated serum AChR (acetylcholine) level. Biopsy shows focal collection of small lymphocytes or *lymphorrhages* around small blood vessels in the interstitial tissue of the affected muscles.

Management

- *Anticholinesterases*—pyridostigmine, edrophonium, and neostigmine, administered intra-muscularly improve the strength of the affected muscles few minutes.
- *Corticosteroids*—these can be used in combination with cholinesterase inhibitors.

- *Thymectomy*—this is done in condition when myasthenia gravis is associated with thymoma.
- *Plasmapheresis* has been temporary valued in patient with severe exacerbation.

Dermatomyositis

It is also called as '*polymyositis*'. It is an acute or a chronic disease of unknown etiology and is characterized by gradual onset with vague and indefinite prodromata, followed by edema, dermatitis, myositis and sometimes neuritis and mucositis.

Clinical Features

- *Age and sex*—it may occur in patients of any age ranging from very young children to elderly, but majority occurs in the 5th decade of life. There is no sex predilection.
- *Onset*—it begins with erythematous skin eruptions, edema, tenderness, swelling and weakness of the proximal muscles of limbs. Fever may be associated with it.
- *Progress*—the weakness of muscle is progressive and characteristically spreads to face, neck, larynx, pharynx and heart.
- *Skin*—the skin becomes the seat of violaceous erythema and edema with a predilection for the eyelids, malar area and dorsa of hands. The typical skin lesions include *heliotrope* (liac-colored) changes around the face and fingers.
- *Signs*—the edema which gives the skin a puffy consistency including the face, leaves a reticulated telangiectatic erythema when it subsides.
- *Calcinosis cutis*—the skin lesions frequently calcify and form calcium carbonate nodules with a foreign body reaction which is known as calcinosis cutis.
- *Calcinosis universalis*—the term calcinosis universalis is applied when these calcified masses are found generalized throughout the soft tissues.
- *Prognosis*—muscle involvement may become severe enough to confine the patient to bed or cause death owing to failure of respiratory muscle.

Oral Manifestations

- *Diffuse stomatitis and pharyngitis*—the oral lesions consist of diffuse stomatitis and pharyngitis and are extremely common.
- *Symptoms*—involvement of the muscles of jaw, tongue and pharynx may pose problems in eating and phonation.
- *Oral mucosa*—the oral mucosa may show dark red or bluish erythema.
- *Tongue*—in the early stages, tongue is swollen and later becomes harder and gradually it becomes atrophic. The tongue may become rigid owing to severe calcinosis.

- *Lips*—telangiectatic lesions of vermillion border of lips and cheeks may also occur.
- *Teeth*—there is purplish black intrinsic staining of teeth.

Radiographic Features

- *Pulp calcification*—there is severe calcification and obliteration of pulp chambers of deciduous and permanent teeth.

Diagnosis

- *Clinical diagnosis*—heliotrope lesion with dark red oral mucosa, calcinosis cutis will give clue to the diagnosis.
- *Radiological diagnosis*—pulp calcification and obliteration is present.
- *Laboratory diagnosis*—the muscle fibers in dermatomyositis exhibit widespread degeneration and hyalinization. Many fibers show vacuolization, granulation and fragmentation with phagocytosis of disintegrating fibers. There is also mild anemia or leukocytosis. In addition, creatinuria is a constant finding as well as elevated levels of serum transaminase and aldolase.

Management

- *Corticosteroids*—corticosteroid should be given but its effectiveness is doubted.

Immunological Disorders

Primary Immune Deficiency

These are hereditary abnormalities characterized by an inborn defect of the immune system. These diseases may involve the B-cell system, T-cell system or a defect in both.

Types

- *Sex linked agammaglobulinemia*—it is caused by a defect in B-cell function with the T-cell function remaining intact. Due to this, these patients lack the ability to synthesize all classes of antibodies including the secretory immunoglobulin, making them more susceptible to bacterial infection. The symptoms begin at 6 months of age.
- *Primary adult immunoglobulin deficiency*—it is characterized by an abnormality of the B-cell or humoral antibody system that does not become clinically apparent until adulthood. Usually one or two Ig classes are deficient. The selective deficiency accounts for the relatively asymptomatic nature of the disease throughout childhood.
- *Thymic hypoplasia*—it consists of *DiGeorge's syndrome* and *Nezelof's syndrome*. These patients have normal

levels a serum immunoglobulin but lack cell mediated immunity. It consists of both, abnormalities of thymus and parathyroid glands. The lack of parathyroid hormone will lead to hypocalcemia and tetany; lack of thymus function causes absent T-lymphocyte response.

- *Secondary combined immunodeficiency*—it can be inherited as either sex-linked or an autosomal recessive trait. In these diseases, there is both T-cell as well as B-cell deficiency. The patients have low peripheral lymphocytes count severe deficiency of immunoglobulin and complete lack of cellular immunity.
- *Immunodeficiency with ataxia telangiectasia*—it is inherited as an autosomal recessive trait. There is combined T-cell and B-cell deficiency. Progressive neurologic disease form severe degenerative changes on the cerebellum, leading to cerebellar ataxia. It becomes apparent when the child begins to walk.

Clinical Features

- *Sex-linked agammaglobulinemia*—patients experience severe recurrent bacterial infections of lungs, meninges, skin and sinuses. There is hypoplasia of lymph nodes, adenoid and tonsils. There is increased incidence of rheumatoid arthritis, dermatomyositis, lymphoma and leukemia.
- *Primary adult's immunoglobulin deficiency*—the most common symptoms include recurrent gram-positive bacterial infections of upper and lower respiratory tracts.
- *Thymic hypoplasia*—there is increased susceptibility to infections with virus and fungi. Infection with *Candida albicans* is especially prominent.
- *Severe combine immunodeficiency*—symptoms begin in first few week of life and include bacterial, viral and fungal infections. Localized and systemic candidiasis is common. The patient dies of overwhelming infections during the first year of life, unless a histocompatible relative is found for a bone marrow transplant.
- *Immunodeficiency with ataxia telangiectasia*—telangiectasia of the skin and eyes becomes apparent at about 3 years of age. The lesion becomes more extensive with age and mainly occurs on conjunctiva, ears and malar eminences. These are also associated with Gonadal dysgenesis and increased incidence of malignancies of lymphoreticular system.

Oral Manifestations

- *Infection*—in T-cell deficiency, there may be chronic oral candidiasis and herpes simplex infection. In B-cell deficiency, there are recurrent bacterial infections and chronic maxillary sinusitis.

- *Congenital defects*—congenital defects like cleft palate, micrognathia, bifid uvula and short philtrum of upper lip.
- *Oral ulcerations*—occasionally, oral ulceration is seen in these patients but it is not the diagnostic of these disorders.

Diagnosis

- *Clinical diagnosis*—increase susceptibility to infection and severe recurrent infection will suspect immune deficiency.

Management

- *Control of local infection*—minimize the chances of local infection or septicemia and oral candidiasis, treated with antifungal therapy, prior to dental treatment.
- *Concentrated human gamma globulin*—patient with symptomatic B-cell abnormalities are usually given continuous therapy with concentrated human gamma globulin. When oral surgery is necessary, an extra dose of gamma globulin should be administered the day before surgery.
- *Blood replacement therapy*—patients with B cell deficiency resulting in the absence of particular immunoglobulin may experience severe transfusion reaction when receiving blood from a patient who has normal immunoglobulin levels. The immunoglobulin acts as a foreign protein and causes an allergic response. For these reasons, patient with selective IgA deficiency must be given IgA depleted blood in blood replacement therapy.

Miscellaneous Conditions

Drug Allergy

Allergy or hypersensitivity is an unwanted response of the body to the complete dose of drug.

Mechanism

- *Formation of antibody*—a patient previously exposed to a drug or other antigen has antibody, primarily IgE, fixed to basophils and mast cells.
- *Releasing of active mediators*—when the antigen in the form of a drug, food or airborne substance is reintroduced into the body it will react with the fixed antibody, bind complement and open the mast cells releasing active mediators such as histamine and slow reactive substance of anaphylaxis.
- *Vasodilation and increases capillary permeability*—these substances cause vasodilation and increased capillary

permeability resulting in fluid and leukocytes leaving the blood vessels and accumulating in the tissue forming areas of edema.

- *Constriction of bronchial smooth muscle*—constriction of bronchial smooth muscle also may result, when IgE is bound in the pulmonary region.

Clinical Features

Localized anaphylaxis

- *Urticaria*—when it involves the superficial blood vessels, urticaria (hives). It begins with pruritus in the area of release of histamine and other active substances.
- *Skin*—wheals (welts) then appear on the skin as an area of localized edema on an erythematous base.
- *Edema*—there is also macular papular or nodular rash with edema of skin and subcutaneous tissue.

Angioneurotic edema

- *Causes*—it can be caused by contact with an allergen or can be idiopathic. A recurrent form is inherited as an autosomal dominant trait. There is deficiency of an alpha-2 globulin, which normally acts as an inhibitor of the first component of complement and kallikrein.
- *Locations*—Angioneurotic edema of lips, tongue, eyelids, larynx and bronchi may occur.
- *Appearance*—in angioneurotic edema, when deeper blood vessels in the subcutaneous tissue are affected, a large diffuse area of subcutaneous swelling is produced under the normal overlying skin.
- *Respiration*—it is temporarily disfiguring, but not serious, unless the posterior portion of the tongue or larynx compromise respiration.

Serum sickness

- *Causes*—it frequently occurs after administration of foreign serum, which before antibiotics, was given for the treatment of infectious disease. It occurs from tetanus antitoxin, rabies antiserum and drugs that combine with body proteins to form allergens.
- *Mechanism*—in it, antibodies form immune complexes in blood vessels with administered antigens. The complexes fix complement, which attract the leukocytes to the area causing direct tissue injury.
- *Symptoms*—major symptoms consist of fever, swelling, lymphadenopathy, joint and muscle pain and rash.
- *Signs*—less common manifestation include peripheral neuritis, kidney disease and myocardial ischemia.

Generalized anaphylaxis

- *Mechanism*—it is an allergic emergency with no time to call consultants. It is reaction of IgE antibodies with an allergen, causing the release of histamine, bradykinin and SRS-A (slow reacting substance of anaphylaxis). These chemical mediators cause contraction of smooth

muscles of the respiratory and intestinal tracts as well as increase vascular permeability.

- *Precipitating factors*—the risk of anaphylaxis is increased if the drugs are given parenterally, family history of allergy, history of asthma and administration of high risk allergens such as penicillin.
- *Onset*—anaphylactic reaction may occur within seconds of drug administration or occur 30 to 40 minutes later. The generalized reaction occurs in four systems cardiovascular, intestinal, respiratory and skin.
- *Skin*—the first sign occurs on skin and it includes urticaria, angioedema, erythema and pruritus.
- *Pulmonary symptoms*—pulmonary symptoms include dyspnea, wheezing and asthma.
- *Gastrointestinal tract*—gastrointestinal tract symptoms like vomiting, cramps and diarrhea occur.
- *Cardiovascular system*—if these are untreated, symptoms of hypotension appear that result from the loss of intravascular fluid. If left untreated, this leads to shock.
- *Prognosis*—the patients with generalized anaphylactic reaction may die from respiratory failure, hypotensive shock or laryngeal edema.

Management

- *Cutaneous rashes*—oral administration or injection of chlorpheniramine, intramuscularly.
- *Angioneurotic edema*—the patient's respiratory distress should be treated immediately with 0.5 ml epinephrine, 1:1000 subcutaneously or 0.2 ml injected slowly intravenously. When immediate danger is passed, then 50 mg of diphenhydramine hydrochloride should be given 4 times daily, until the swelling is diminished.
- *Severe symptoms*—injection hydrocortisone sodium succinate or injection epinephrine.
- *Serum sickness*—It is self-limiting with spontaneous recovery within 1 to 3 weeks. Other treatment is symptomatic with aspirin, for arthralgia and antihistamines, for skin rashes.
- *Anaphylactic reaction* with sudden cardiovascular and respiratory collapse can be treated by following method:-
 - Make the patient to lie down in supine position.
 - Patent airway is to be maintained.
 - Administer 100% O₂.
 - Injection epinephrine 1.1000 IM. It should be given if the blood pressure falls below 60 mm of Hg.
 - For bronchospasm, slowly inject aminophylline 250 mg IV over a period of 10 minutes. Too rapid administration can lead to fatal cardiac arrhythmias.
 - Start IV infusion stat.
 - Monitor pulse, blood pressure and respiration.
 - Hydrocortisone 100 mg IV.

- Antihistaminic should be given.
- Refer to physician and arrange for hospitalization.

Syncope

It is also called as 'simple faint', 'swoon', 'psychogenic syncope', and 'vasodepressor syncope'. It is a transient loss of consciousness due to cerebral anoxia.

Causes

- *Young and poor health person*—it is commonly seen in younger individuals and people having poor health.
- *Precipitating factors*—the other factors are anxiety, fear, and sight of blood, pain, exhaustion, fasting and hot environment. These emotional stresses induce release of increased amount of catecholamine.
- *Cerebral anoxia*—the chief cause is cerebral anoxia or anemia. A blood loss of one liter will cause fainting.

Clinical Features

- *Presyncope*—victim falls gently to the floor, regains consciousness almost immediately or within a short period of time, appears to recover completely.
- *Early signs and symptoms*—the patient complains for warmth in the neck and face. He bathes in beads of cold sweat. He also complains of nausea and feeling vague. Blood pressure at this time is at baseline or slightly lower than baseline. There is also rapid heart rate. Face is pale or has ashen gray skin tone.
- *Late signs and symptoms*—as the process continues papillary dilation, yawning, hyperpnea, coldness in hand and feet, hypotension, bradycardia, visual disturbances, dizziness and loss of consciousness occur.
- *Syncope*—with loss of consciousness, breathing may become irregular, jerky and gasping. The pupils of eye dilate and patient has deathlike appearance. Convulsive movements or muscular twitching of hands, legs or facial muscle. Blood pressure is low and pulse rate is also decrease.
- *Post syncope*—with proper positioning, recovery usually appears rapidly. Patient exhibits pallor, nausea, weakness and sweating, which may persist for few minutes to few hours.

Management

- *Supine position*—when there are signs of fainting he/she should be made to lie down in supine position with legs raised to improve venous return to the heart (**Fig. 33-17**). In case of patient being on the dental chair the back of the chair should be immediately lowered so that the head of the patient is at a lower level than the feet.

Fig. 33-17: Supine position to be maintained in the syncope.

- *Loosening of tight clothing and belt*—tight clothing and belt should be loosened.
- *Maintenance of patent airway*—a patent airway should be maintained. Inhalation of aromatic spirit or application of cold sponge to the face helps in securing reflex stimulation.
- *Oxygen administration*—if cyanosis is developing, 100% oxygen is administered and vital signs are recorded.
- *Ammonia ampule*—an ammonia ampule is crushed and held under the patient's nose for speed recovery.
- *After recovery*—after complete recovery, patient should be slowly brought to semi-reclining, rather than sitting, position.
- *Prevention*—it is usually advisable to treat patients in supine or semi-reclining position. The role of pre-medication before surgery should be considered. Patient who is fasting is more prone to vasovagal attack.

Shock

If the primary shock or syncope is not tackled and allowed to persist, the secondary or true shock appears. Shock can be hemorrhagic, hypovolemic, septic, anaphylactic shock.

Clinical Features

- *Symptoms*—the patient is unconscious with ashen gray face and cold clammy skin.
- *Signs*—mucous membrane is pale, whereas lips, nails, fingertips and lobules of ear are grayish blue. Pulse is weak and thready.
- *Face*—face is expressionless with sunken eyes.
- *Pupil*—pupils are dilated, but react feebly to light.

Management

- *Establishing the cause*—establish the cause of shock like loss of blood, extremely painful stimulus, emotional reasons, toxemia or anaphylaxis and the treatment should be given.
- *Patient position*—put the patient in position with head at lower level than feet.
- *Maintenance of body heat*—maintain the body heat by covering the patient with blanket and keeping a hot water bottle between the thighs.
- *Airway management*—check the patency of airway and control the loss of blood by pressure packs, ligation of vessels or crushing of bone.
- *Restoration of body fluids*—restore the lost body fluids; Ringer's lactate solution should be used to maintain the intravenous line and to restore the volume loss. If hemoglobin is fallen due to toxemia, packed cells are given.
- *Oxygen*—administer 100% of oxygen to the patient for adequate oxygenation of the body tissue.
- *Monitoring of vital signs*—the blood pressure, pulse rate and respiration rate should be constantly monitored to assess signs.
- *Steroids injection*—injection hydrocortisone sodium hemisuccinate 100 mg, dissolved in 5 ml of sterile water is given.
- *Mephentermine injection*—injection mephentermine is given for hypotension.
- *Injection atropine*—if pulse is weak injection atropine is diluted with 5 ml of distilled water and is injected slowly till the radial pulse becomes palpable.
- *Antibiotics*—broad spectrum antibiotics through IV route are given.
- *Adrenaline*—one ampule of 1:1000 dilution of adrenaline in 10 ml of sterile water is given intravenously.
- *Painkiller*—a potent painkiller like narcotic analgesic to gain relief from pain.

Diseases of Bone Manifested in Jaw

4

Introduction

Bone is a dense calcified tissue which is specifically affected by a variety of disease that often causes it to react in a dynamic fashion. These diseases of bone may arise at any age; some are congenital and present at birth, while other develop in early childhood or in young adulthood.

Fibro-osseous Lesions

In it, normal bone is replaced by benign fibrous tissue showing varying amounts of mineralization. The subject of benign fibro-osseous enlargement of the jaws has many facets, the most sinister of which is the possibility that a healthy good looking person may take on a monstrous appearance.

Classification

First Classification

- *Fibro-osseous lesions of medullary bone origin*
 - Fibrous dysplasia
 - Fibro-osteoma
 - Cherubism
 - Juvenile ossifying fibroma
 - Giant cell tumor
 - Jaw lesions in hyperparathyroidism
 - Paget's disease
- *Fibro-osseous lesions of periodontal origin*
 - Periapical cemental dysplasia
 - Florid osseous dysplasia
 - Cemento-ossifying fibroma
 - Cementifying fibroma
 - Ossifying fibroma

Second Classification

Second classification given in 1993 by Waldron reclassified these lesions as follows:

- *Fibrous dysplasia*
- *Reactive (dysplastic) lesions arising in the tooth bearing area*—These are presumably of periodontal ligament origin. Depending on their reference they are divided into three types although they seem to represent the same pathologic process:
 - Periapical cemental dysplasia
 - Focal cemento-osseous dysplasia
 - Florid cemento-osseous dysplasia
- *Fibro-osseous neoplasms*—These are widely designated as cementifying fibroma, ossifying fibroma, or cemento-ossifying fibroma.

Fibro-osseous Lesions of Medullary Bone Origin

Fibrous Dysplasia

It arises from the bone forming mesenchyme in the spongiosa and develops by proliferation of fibrous tissue. Lichtenstein in 1938 coined the term 'fibrous dysplasia'. It is also called as 'fibrocystic disease', 'osteitis fibrosa localisata', 'focal osteitis fibrosa' and 'fibro-osteodystrophy'.

There is no general agreement as to the etiology of lesion. It appears to have no familial, hereditary or congenital basis.

Etiopathogenesis

- *Developmental*—Jaffe and Lichtenstein considered it as a developmental anomaly caused by aberrant activity in the bone forming mesenchymal tissue. Most theories

favor a developmental anomaly because the disease begins in early life and is active during the growth period.

- *Endocrine disturbances*—Sternberg and Joseph considered complex endocrine disturbances with local tissue susceptibility as the cause.
- *Genetic*—fibrous dysplasia results from postzygotic mutation in GNAS I (guanine nucleotide binding protein) gene. If mutation occurs in early embryonic period, the polyostotic type of fibrous dysplasia will occur. If mutation occurs during postnatal life, monostotic type of fibrous dysplasia occurs.

Classification

First classification

- *Monostotic fibrous dysplasia*—in it, only one bone is involved.
- *Polyostotic fibrous dysplasia*—in it, more than one bone is involved
 - *Jaffe type*—fibrous dysplasia involving variable number of bone, accompanied by pigmented lesions of the skin or 'Café-au-Lait' spots.
 - *Albright's syndrome*—a severe form of fibrous dysplasia involving nearly all the bones in the body, accompanied by pigmented lesions of the skin plus endocrine disturbances of various types.

Second according to Stewart

- *Monostotic*—indicates involvement of a single bone.
- *Monomelic*—it refers to the involvement of one extremity and is rarely found.
- *Polyostotic*—many bones involved.
- *Albright's syndrome*

Subclinical fibrous dysplasia

Many a times, an unsuspected lesion of fibrous dysplasia comes to light accidentally on routine radiographic examination, without any clinical evidence of the suspected disease. Such examples are termed as subclinical fibrous dysplasia.

Clinical Features

Monostotic fibrous dysplasia

- *Age and sex*—fibrous dysplasia discovered in young patients, usually in children younger than 10 years affecting both the sexes equally.
- *Sites*—monostotic fibrous dysplasia involves only one bone and presents no extra-skeletal effects, other than occasional pigmented skin lesions. Most frequent sites are ribs, femur, maxilla and mandible.
- *Appearance*—swelling is seen on affected site (**Fig. 34-1**).

Polyostotic fibrous dysplasia (Jaffe's type)

- *Sex*—polyostotic fibrous dysplasia involves multiple bones, with female to male ratio of 3:1.
- *Sites*—the most common site for these are the back, buttocks, thighs, shoulders, chest, neck and face in the mentioned order.
- *Skin lesions*—the skin lesions consist of irregularly pigmented, light brown melanotic spots, described as 'café-au-lait spot'.
- *Symptoms*—recurrent bone pain is the most common presenting skeletal symptom.
- *Skeletal lesions*—skeletal lesions may be unilateral in distribution or may involve nearly all bones of the body. Skeletal lesions become static with the cessation of growth but proliferation may continue, particularly in the polyostotic form.
- *Complication*—spontaneous fracture is a common complication.
- *Signs*—in rare cases, continuous and inexorable extension result in great deformity and blindness.

Fig. 34-1: Monostotic fibrous dysplasia showing swelling on face (Courtesy Dr Parate).

McCune-Albright's syndrome

- *Sex*—Albright's syndrome is exclusively found in females.
- *Features*—Albright's syndrome, in addition show, endocrinal disturbances like precocious puberty, goiter, hyperthyroidism, hyperparathyroidism, Cushing's syndrome and acromegaly.
- *Café au lait spot*—these are coffee with milk color spot. There is irregular flat area of increased skin pigmentation.
- *Symptoms*—vaginal bleeding has been noted.
- *Signs*—secondary sexual characteristics such as pubic and axillary hair and development of breasts are evident by the age of 5 years. It may result in crippling deformities or fracture

- *Precocious puberty*—it is rare in boys and is manifested as gynecomastia.
- *Sites*—long bones are frequently affected.
- *Prognosis*—generally, the active period ceases in adult life. If growth continues the rate of activity is markedly reduced. However, calcification of the fibrous tissue may continue for years. Occasionally, the lesions may remain inactive for several years. For some unknown reasons they may renew the activity.

Oral Manifestations

Monostotic

- *Sites*—maxilla (**Fig. 34-2**) is more commonly affected than mandible, with most changes occurring in the posterior region. Most common area involved is premolar-molar area.
- *Symptoms*—swelling is usually painless but patients may feel discomfort in some cases and while others complain of frank pain.
- *Cortical plates*—enlarging deformities of alveolar process mainly buccal and labial cortical plates.
- *Mandible*—in mandible, it causes protuberant excrescence of the inferior border of mandible.
- *Teeth*—the teeth present in the affected area are either malaligned (**Fig. 34-4**) and tipped or displaced. Dental anomalies such as supernumerary teeth have been reported in connection with the monostotic fibrous dysplasia. The most commonly affected site is maxillary midline and mandibular premolar region. These supernumerary teeth often remain impacted and may affect the eruption of normal teeth.

Fig. 34-2: Swelling seen on right side in maxillary region in case of fibrous dysplasia.

- *Appearance*—there may be unilateral facial swelling, which is slow growing with intact overlying mucosa (**Fig. 34-3**).

Fig. 34-3: Unilateral swelling seen on right side with intact overlying mucosa (Courtesy Dr Bande).

Fig. 34-4: Malalignment of teeth seen in upper arch on right side due to fibrous dysplasia (Courtesy Dr Ashok L).

Craniofacial fibrous dysplasia

- *Sites*—if fibrous dysplasia extends to involve the maxillary sinus, the zygomatic process, floor of orbit and sometimes, it extends toward the base of the skull, known as craniofacial fibrous dysplasia.
- *Symptoms*—it results in severe malocclusion and marked facial deformity. Craniofacial lesions may lead to anosmia (loss of sense of smell), deafness and blindness.
- *Signs*—there may be proptosis of the affected eye.

Polyostotic

- *Appearance*—expansion and deformities of jaws. Asymmetry of facial bones. There is ballooning of jaws, so there is gross enlargement and deformity.
- *Teeth*—the eruption pattern of teeth is disturbed because of loss of support of the developing teeth.
- *Pigmentation*—in some cases, intraoral pigmentation can be seen.

Radiographic Features

Lesions showing predominance of fibrous tissue

- *Early*—radiolucent with ill defined borders. The bony defect may be often unilocular but occasionally bony septa may be apparent creating an impression of multilocular cavity.
- *Margins*—margins may be well defined with a tendency to blend imperceptibly with surrounding normal bone.
- *Granular appearance*—surrounding the margins of the radiolucent area, there may be wider band of increased density, but granular in appearance (**Fig. 34-5**).
- *Lamina dura*—when the lesion involves the apices of teeth there is loss of lamina dura or if retained, it has less density than normal.
- *Teeth*—resorption of roots and destruction of developing teeth.
- *Jaws*—when the lesion comes to the surface, there may be expansion of the jaws.

Fig. 34-5: Granular type appearance seen in fibrous dysplasia patient.

Lesions showing mixed radiolucent and radiopaque appearance

- *Appearance*—radiographic appearance of lesions with heterogeneous distribution of fibrous and osseous tissue shows a mixed radiolucent and radiopaque appearance, depending on the maturity of the lesions (**Fig. 34-6**).
- *Granular appearance*—the new bone takes the form of very small opacities of poor density. When they become larger they appear as granular.
- *Maxillary lesion*—it may spread to involve the adjacent bone such as zygoma, sphenoid, occiput and base of skull.

Fig. 34-6: Mixed type lesion seen in fibrous dysplasia,

Mature radiopaque lesions where bone is predominant

- *Stippled*
 - *Orange peel*—the radiograph shows bone of increased density. The normal structure of bone is replaced by a stippled appearance which resembles the ring of orange which is called as 'orange peel'.
 - *Teeth*—tilting and bodily displacement of teeth in the affected area.
 - *Maxillary sinus*—it may obliterate the maxillary sinus.
 - *Thumb print appearance*—when mandible is affected, the vertical depth of mandible is increased. The inferior border of mandible appears as a ribbon like cortex. In some cases, the localized area over the cortex is lost and instead, there is a smooth curved downward projection of the inferior margins of the bone. The appearance resembles a 'thumb print' (**Fig. 34-7**), as if the bone had been soft and pressed upon by the thumb.
 - *Expansion*—bony expansion usually extends to the buccal and distal aspect.
 - *Smoky mottled appearance*—as the lesions mature, dysplastic bony trabeculae increase in size and number and appear like smoky mottled radiopacities.
- *Granular appearance*
 - *Ground glass appearance*—another characteristic appearance of fibrous dysplasia is ground glass appearance, also termed as granular. Apart from the appearance everything else is similar as in stippled type. It may demonstrate areas of whorled amorphous partially calcified materials that are well circumscribed.

Fig. 34-7: Thumb print appearance seen in fibrous dysplasia.

- *Dense structureless, homogeneous*—in this, the lesion shows a dense structureless, homogeneous appearance (Fig. 34-8). Any part of the joint may be affected. The commonest site is the base of the skull with involvement of the maxilla and nasal bones. Encroachment or obliteration of the antrum and spread into the adjacent bone including the base of skull take place.
- *CT features*—CT is useful to evaluate the extent of facial lesions; especially orbital involvement. The CT characteristics of the fibrous dysplasia include expansion of the involved bones in a heterogeneous pattern with scattered or confluent islands of bone formation (Fig. 34-9). CT attenuation (density) values can reach 34 to 513 Hounsfield units or more particularly in dense lesions. The variation in the values reflects the complex, and often non-uniform, distribution of primitive bony trabeculae.

Fig. 34-8: Homogeneous pattern of fibrous dysplasia seen on computed tomography (Courtesy Dr Iswar).

Fig. 34-9: Confluent pattern seen on CT scan on right side in case of fibrous dysplasia.

Obisesan et al classified the lesions of fibrous dysplasia radiographically into 6 types.

- *'Peau d' orange' or orange peel*—in this type, there are alternating areas of granular density and lucency giving a radiographic appearance resembling the ring of orange.
- *Whorled plaque like type*—in this type, the matrix of the well circumscribed lesion is composed of plaques of amorphous material of intermediate radiodensity, which on close examination are seen to be arranged in whorled onion peel appearance.
- *Diffuse sclerotic type*—the lesions of this show as homogeneous dense area, which gradually merges with the normal bone.
- *Cyst like type*—in this type, the lesions are radiolucent. It is unilocular or multilocular, more often multilocular with well defined margins.
- *Pagetoid type*—in this type of lesions, the affected area of bone markedly expands and shows alternating areas of radiopacities and lucency, as those seen in Paget's disease of bone.
- *Chalky type*—it manifests itself as a well circumscribed lesion consisting of an amorphous dense radiopaque material.

Craniofacial fibrous dysplasia

- *Density*—radiograph reveals the presence of a marked density which encroaches to a variable degree upon the orbit and antral cavity.
- *Granular type*—changes in the base of the skull is of granular type and structureless, so that affected portion of the bone is thickened and of greater density.

- *Frontal bone*—the frontal bone is also thickened with homogeneous or variegated type of density.
- *Nasal septum*—the nasal septum is grossly thickened, dense and curved, so that it represents the gross caricature of the letter S.

Diagnosis

- *Clinical diagnosis*—painless swelling seen in the maxillary region with intact mucosa. Café au lait spots are seen.
- *Radiological features*—ground glass appearance, granular appearance is seen.
- *Laboratory diagnosis*—when the polyostotic lesions are numerous and active, the serum alkaline phosphatase levels may be elevated in 50% of the cases. Biopsy shows bone made up of proliferating fibroblast in a compact stroma of interlacing collagen fibers. Irregular trabeculae of bone are scattered throughout the lesion, with no definite pattern of arrangement. Some of these trabeculae are C-shaped and described as Chinese character shaped.

Differential Diagnosis

Lesions are likely to be confused in the osteolytic stage of fibrous dysplasia

- *Central giant cell granuloma*—it has got faint wispy trabeculae coursing through it whereas internal calcifications may occur in fibrous dysplasia and appear to be stippled and granular appearance.
- *Traumatic bone cyst*—there is no cortical bulging and displacement of teeth.
- *Dental cyst*—it has a thin, well defined cortex which is smooth, while in fibrous dysplasia, cortex tends to be wider and more granular in appearance.
- *Aneurysmal bone cyst*—there is hemorrhagic aspirate.
- *Chronic osteitis*—it is always associated with the roots of pulp less teeth.
- *Chronic osteomyelitis*—it manifests itself in older age group (30-80 years) as compared to fibrous dysplasia (10-20 years). In addition, patients with osteomyelitis will give a history of trauma, fracture or any debilitating systemic disease.
- *Peripheral and central squamous cell carcinoma*—it also occurs in older age group and shows a predilection for mandible. Fibrous dysplasia grows by slow expansion whereas central and peripheral squamous carcinoma spreads rapidly.
- *Metastatic tumor*—seen in older age groups and shows a predilection for premolar-molar region of mandible.
- *Reticular cell sarcoma and Ewing's sarcoma* are rarely seen in maxilla.

The mottle type of fibrous dysplasia

- *Lymphoma of bone*—is rare and is poorly defined. The radiographic pattern is irregular and bizarre. In fibrous dysplasia smooth, well contoured external bony borders are always maintained.
- *Chondrosarcoma*—is an uncommon malignant tumor of the jaws which is often painful and affects a much older age group than fibrous dysplasia.
- *Osteoblastic metastatic carcinoma*—seldom shows a monotonous pattern as in fibrous dysplasia. A history of either symptoms or treatment for a primary tumor elsewhere will be elicited during history taking. Osteoblastic metastatic carcinoma is found in older age group.
- *Osteosarcoma*—its appearance is disorderly with sunburst pattern, codmans triangle and asymmetrical band like widening of the periodontal ligament.
- *Paget's disease*—classically, Paget's disease simultaneously affects several bone of the skeleton. It is a disease of the later age group; the serum alkaline phosphatase level is elevated in Paget's disease whereas in fibrous dysplasia, it is within normal limit. Rare in adolescents and young adults. Bilateral involvement.
- *Cementifying and ossifying fibroma*—it exhibits a similar mottled appearance to that seen in fibrous dysplasia. The following differences are recognized.
 - *Shape*—cementifying and ossifying fibroma as predominantly rounded while those of fibrous dysplasia are more rectangular.
 - *Jaw expansion*—jaw expansion caused by cementifying and ossifying fibroma is usually nodular or dome shaped whereas in fibrous dysplasia it is usually the elongated fusiform type.
 - *Margins* of fibrous dysplasia are indistinct, blending imperceptibly with normal bone while in cementifying and ossifying fibroma, the margins are sharply defined.
 - *Predominance in jaws*—approximately 70% of cementifying and ossifying fibroma occur in mandible while fibrous dysplasia shows a slight predilection for maxilla.
 - *Predominant age*—the age range for cementifying and ossifying fibroma is from 7-58 years. The majority of active cases of fibrous dysplasia are found in patients under the age of 20 years.
- *Chronic osteomyelitis*—in it, radiolucent-radiopaque appearance can mimic the mottled appearance of fibrous dysplasia. Generally, when purulent discharge is present, the diagnosis is of chronic osteomyelitis.

Mature phase

- *Paget's disease and giant cell lesion of hyperparathyroidism*—a solitary painless fusiform enlargement, which is firm smooth, covered by normal mucosa and has a

radiopaque ground glass appearance, occur in the jaw bones of relatively young person is almost certainly fibrous dysplasia. Paget's disease and giant cell lesions of hyperthyroidism can produce ground glass appearance but the overall effect is rarefaction and not radiopacities.

Management

- *Surgical*—surgical removal of the lesion should be carried out.
- *Osseous contouring*—it is necessary for correcting the deformity for esthetics or pre-esthetic purposes.

Juvenile Ossifying Fibroma

It is also called as 'young ossifying fibroma', 'juvenile aggressive ossifying fibroma', and 'trabecular desmoosteoblastoma'. This name has been given as this occurs in younger age group.

Classification

Slootweg and colleagues have separated the lesions into two distinct groups:

- *Juvenile ossifying fibroma WHO type*—it occurs predominantly in the maxilla and mandible. Here, the designation of juvenile ossifying fibroma should be restricted exclusively to those lesions whose histomorphology is consistent with that described in the 1992 WHO monograph on jaw lesions. This trabecular variant has strands of immature cellular osteoid within the lesion and usually occurs in childhood with a slight maxillary predilection.
- *Juvenile ossifying fibroma with psammoma like ossicles*—it occurs in the paranasal sinuses and extragnathic bones. The psammomatoid variant has small spherical ossicles surrounded by osteoid rims within the lesion. It occurs over a wider age range than the trabecular variant and usually affects the orbit or paranasal sinuses.

Clinical Features

- *Age*—it is seen under the age of 15 years.
- *Site*—no site predilection and with equal frequency in both the jaws. Although there is report that this is more commonly found in maxillary region.
- *Symptoms*—the presenting clinical symptom is of swelling (Fig. 34-10).
- *Effect on surrounding structure*—neoplasm can impinge on neighboring structure. Due to impingement, patient may noticed nasal obstruction, exophthalmos and proptosis. In some cases, permanent blindness may occur.
- *Intracranial extension*—in some cases, meningitis may arise due to intracranial extension.

Fig. 34-10: Swelling seen in maxillary region due to ossifying fibroma.

Radiographic Features

- *Internal structure*—it may appear as unilocular or multilocular lesion.
- *Appearance*—it may be radiolucent or show mixed appearance containing radiopaque foci (Fig. 34-11).
- *Margin*—it has got distinct radiopaque border.

Fig. 34-11: Juvenile ossifying fibroma showing mixed radiopaque radiolucent lesion (Courtesy Dr Bande).

Diagnosis

- *Clinical diagnosis*—it is not possible to make clinical diagnosis.
- *Radiological diagnosis*—mixed lesion in young patient will give clue to the diagnosis.
- *Laboratory diagnosis*—biopsy shows non-encapsulated lesion. There are also myxomatous foci, nuclear crowding, and multinucleated osteoclasts.

Differential Diagnosis

- *Ossifying fibroma*—juvenile ossifying fibroma occurs at a far lower mean age (8.5 years) than ossifying fibroma (26.4 years). Ossifying fibroma contains lamellar bone and cementicles as well as smoothly contoured cells, poor curvilinear trabeculae, features that are absent in juvenile ossifying fibroma.

Management

- *Excision*—complete local excision of tumor is the treatment of choice.

Cherubism

It is also known as 'familial fibrous dysplasia of the jaws', 'disseminated juvenile fibrous dysplasia', 'familial multilocular cystic disease of the jaws' and 'Hereditary fibrous dysplasia of the jaws'. Above terms of cherubism are related to fibrous dysplasia but there is no similarity between fibrous dysplasia and cherubism so, this term should be avoided.

The clinical entity was first described by Jones in 1933 who coined the term 'Cherubism' reflecting the characteristic of chubby facial appearance similar to plump cheeked little angle (cherubs) seen in Renaissance painting. It is autosomal dominant inherited fibro-osseous disease that affects only the jaws causing bony expansion.

Classification

It depends on the severity and location of the lesion and the extent to which jaws are affected.

- *Grade I*—the fibro-osseous expansion tends to be bilateral and symmetrical. It is primarily in the ramus of the mandible.
- *Grade II*—in more severe cases, the ramus and the body of the mandible are involved resulting in congenital absence of the third and occasionally the second mandibular molar teeth. In this group, the tuberosity region of the maxillae is also affected.
- *Grade III*—in these cases, the lesions affect the mandible and maxilla entirely and may result in considerable facial deformities.

Etiology

- *Developmental defect*—anomalous development of dental structures with disturbance in the development of bone forming mesenchyme may lead to this condition.
- *Hormonal*—cherubism can be present in latent hyperparathyroidism and hormone dependent benign neoplasm.
- *Other*—other factors which are responsible for cherubism are trauma and an aberration in ossification.

Clinical Features

- *Age and sex*—early childhood between the ages of 2 to 4 years males are affected about twice as frequently as females.
- *Sites*—it shows predilection for angle of mandible bilaterally and occasionally posterior maxilla.
- *Appearance*—in the rapidly increasing stage, the child assumes a *chubby, cherubic facial appearance* (Fig. 34-12), especially if combined with involvement of the orbital floor with upward displacement of the globe and exposure of the scleral rims. This appearance results due to bilateral involvement of posterior mandible.

Fig. 34-12: Cherubic appearance of the child in cherubism.

- *Symptoms*—the patient may have difficulty in speech, deglutition, mastication, respiration and limited jaw movement.
- *Signs*—swelling is firm and hard on palpation (Fig. 34-13). Overlying mucosa is intact and non-painful.

Fig. 34-13: Firm swelling seen in the jaw of patient of cherubism.

- *Jaws*—bilateral enlargement of mandible in this condition produces full, round lower face. Bilateral enlargement of maxilla gradually follows.
- *Eye raised to heaven*—pulling or stretching of skin of the cheek, depresses the lower eyelid, exposing a thin line of sclera and resulting in the so called “eyes raised to heaven” look.
- *Orbital floor*—tumor encroachment on the orbital floor often causes partial obliteration of the palatal vault with resulting ‘V’ shaped cleft.
- *Alveolar process*—the alveolar process are so wide, as to occupy almost the whole of the roof of the mouth; the actual palate being reduced to a narrow fissure between the two approximating alveolar process.
- *Lymph nodes*—there may be enlargement of sub-mandibular lymph nodes.
- *Progress*—there is rapid increase in size up to 7-8 years of age, after which the lesions become static or progress very slowly until puberty. After puberty the maxillary lesions tend to regress. The mandibular lesions progress slowly up to the age of 20 years and then regress; the facial appearance almost returns to normal in the 4th and 5th decades of life.
- *Teeth*—the fibrous replacement of bone displaces the deciduous dentition. The primary teeth may be irregularly spaced and some may be absent. There is premature loss of primary teeth. The developing permanent teeth are affected, giving rise to displaced unerupted or absent teeth along with malocclusion.

Radiographic Features

- *Radiodensity*—cyst like radiolucency of mandible, bilaterally symmetrical which is up to several centimeters in diameter.
- *Progress*—initiation of bone destruction near the angle of the mandible with later expansion of lesions posteriorly into ramus and anteriorly into the mandibular body.
- *Appearance*—it appears as a classic multilocular cavity due to internal radiopaque septa, which tends to coalesce as they enlarge. On posteroanterior views, teeth are seen to be hanging in air.
- *Margins*—they are well defined, well corticated and smooth around most of the radiolucency.
- *Effect on surrounding structure*—there is also expansion of buccal and lingual cortical plates (Fig. 34-14). In mandible, the inferior alveolar canal may be displaced and the lesion may occupy alveolar process, the angle and the ramus. The thin cortex may eventually disappear. Maxillary lesions enlarge at the expense of maxillary sinus.
- *Effect on teeth*—displacement of numerous teeth but prior to enamel calcification. Erupted deciduous teeth in the

area of bone involvement shed prematurely. Few posterior teeth may be missing due to early developing expanding masses which destroy the buds and incipient follicle.

Fig. 34-14: CT scan of patient of cherubism showing bilateral swelling in mandibular posterior region (Courtesy Dr Iswar).

Diagnosis

- *Clinical diagnosis*—typical cherubic appearance of child with bilateral swelling in the jaw
- *Radiological diagnosis*—cyst like radiolucency present bilaterally in the mandible
- *Laboratory diagnosis*—in active cases, serum alkaline levels may be raised. Biopsy shows large multinucleated giant cell in a loose delicate fibrillar connective tissue stroma.

Differential Diagnosis

- *Fibrous dysplasia*—cherubism is bilateral.
- *Giant cell granuloma*—it occurs frequently in the anterior segment of mandible in contrast to cherubic lesions, which are seen in the posterior part of mandible.
- *ABC*—the lesions of ABC are tender, whereas cherubic lesions are painless.
- *Central hemangioma*—there is localized gingival bleeding and pumping tooth syndrome.
- *Giant cell lesions of hyperthyroidism*—are not bilateral and they can be differentiated on abnormal blood chemistry levels.
- *Metastatic tumors*—it is seen in older age group as compared to cherubism and also there will be signs and symptoms or history of primary tumor elsewhere in the body.
- *Ameloblastoma*—it is seen unilaterally and frequently in an older age group than that of cherubism
- *Odontogenic myxoma*—history of missing tooth, as it is of developmental origin.

- *Nevoid basal cell carcinoma*—no facial swelling is seen in cherubism. There are characteristic cutaneous abnormalities or rib anomalies seen on chest radiograph.
- *Multiple dentigerous cyst*—impacted teeth present.

Management

- *Surgical contouring*—surgical procedures should be delayed, as long as possible, as the cystic lesion defect usually becomes static and regresses during adulthood. Occasionally, surgical contouring of the lesions is necessary to improve esthetics and in case of active growth.
- *Homogeneous bone grafts*—in cases of extensive involvement, homogeneous bone grafts can be given to prevent pathological fractures of mandible.
- *Orthodontic care*—orthodontic care may be required to ensure proper alignment of the teeth.
- *Calcitonin*—this therapy is under trial nowadays, awaiting results of some study.

Central Giant Cell Granuloma

It is a non-neoplastic bone disease reactive to some unknown stimulus. It was first described in the jaws by Warren 1837. It has been called as *osteoclastoma*, *myeloid sarcoma*, *chronic hemorrhagic osteomyelitis* and *giant cell reparative granuloma* initially. But nowadays the term reparative is dropped and it is called as *giant cell granuloma* only.

Types

- *Non-aggressive*—it exhibits slow growing benign behavior.
- *Aggressive*—it shows typical features of rapidly growing, destructive lesion.

Clinical Features

- *Age*—lesion of adolescent and young adult with 60% cases in younger than 20 years and 74% cases in younger than 30 years.
- *Sites*—mandible is twice as frequently involved than maxilla, with anterior half showing greatest incidence with fairly high percentage crossing the symphysis. The commonest site being the anterior and bicuspid region in mandible and the canine fossa and ethmoid region in maxilla.
- *Symptoms*—the earliest sign of the lesion may be expansion of bone with premature loosening and shedding of deciduous teeth. There is jaw swelling associated with facial asymmetry. Usually painless, but local discomfort may be noted.

- *Signs*—palpation may elicit tenderness. Growth is slow.
- *Teeth*—teeth in the area may become mobile but maintain their vitality, until they are exfoliated.
- *Prognosis*—recurrence rate of 12% for lesions under 2 cm and 37% recurrence for lesions over 2cm in size.

Radiographic Features

- *Radiodensity*—solitary unilocular (**Fig. 34-15**) or multilocular radiolucency.

Fig. 34-15: Unilocular radiolucency seen in mandibular anterior region.

- *Location*—it may occupy whole of the mandibular body and may extend past the midline to the opposite side (**Fig. 34-16**).
- *Appearance*—as it grows, it causes bossing of buccal cortex i.e. uneven, variable bulging or undulation of the cortical contour.
- *Margins*—borders may be smooth, undulating, moderately well defined and moderately well corticated.
- *Honeycomb appearance*—it shows bony trabeculation within their contour and tends to be mildly wavy on close inspection. It may have wispy delicate quality. Sometimes, they may have honeycomb appearance.

Fig. 34-16: Radiolucency seen in mandible crossing the midline.

- *Effect on surrounding structures*—when they involve maxillary bone, they may erode or expand bone. Displacement of adjacent teeth, tooth buds and resorption may occur.

Diagnosis

- *Clinical diagnosis*—expansive swelling in the anterior region of mandible may suspect central giant cell granuloma.
- *Radiological diagnosis*—radiolucency crossing the midline is typical of central giant cell granuloma (**Fig. 34-17**).
- *Laboratory diagnosis*—biopsy shows loose fibrillar connective tissue stroma with many interspersed proliferating fibroblast and small capillaries. Multinucleated giant cells are prominent.

Fig. 34-17: CT scan of central giant cell granuloma showing destructive lesion in mandibular anterior region

Differential Diagnosis

- *Ameloblastoma*—it is uncommon in a younger age range, which is most susceptible to giant cell granuloma. Seen in posterior mandible in contrast to giant cell granuloma which occurs anterior to the first molar. Ameloblastoma demonstrates internal, hard curved arch like septa whereas giant cell granuloma has lighter wispy septa. Ameloblastoma is usually multiloculated.
- *Aneurysmal bone cyst*—it does not occur in anterior segment of mandible. Aspiration produces blood.
- *Odontogenic myxoma*—multiloculated and typical honey-comb appearance. Missing or impacted tooth is usually a finding.
- *Giant cell tumor*—it is described in **Table 34.1**
- *Traumatic bone cyst*—no bodily movement of teeth is present. No expansion of overlying bone cortex.
- *Fluid filled odontogenic cyst*—internal septa are not present. No bony spicules protrude from radiographic margins. Regular smooth bony expansion of cortical plates while scalloped, undulating bulging of cortex.
- *Brown tumors of hyperthyroidism*—serum calcium levels are elevated.
- *Cherubism*—it is bilateral in the posterior part of mandible and there is history of familial involvement. It does not cross the midline.
- *Metastatic tumors*—it is seen in older age groups and also predominant lesions are multilocular with history and symptoms of primary tumor in addition to local lesions.
- *Central hemangioma*—it shows localized bleeding around the necks of teeth and also the pumping tooth syndrome.
- *Post extraction socket, surgical defect and residual cyst*—it can mimic unilocular appearance of central giant cell granuloma. Patients with surgical defect will give a history of previous surgery and history of extraction in residual cyst and post extraction socket.

Table 34.1: Difference between giant cell tumor and giant cell granuloma

<i>Giant cell tumor</i>	<i>Central giant cell granuloma</i>
It is more common in 3rd and 4th decades and unusual in patient below 20 years of age common in males	It occurs mainly in children and young adults often in females
Common in long bone like femur, tibia and rare in jaw	Most common in mandible, appearing anterior to 1st molar tooth bearing area
Microscopically tumor giant cell contains more nuclei and has larger dimension	It contains fewer nuclei and smaller dimension
Even distribution of giant cells throughout the tumor, in every field	In it giant cells are unevenly distributed
It is not preceded by trauma	It is preceded by trauma
New bone formation is absent	Foci of osteoid and new bone are frequently present

Management

- **Curettage**—thorough curettage of the lesion should be carried out.
- **Corticosteroids**—weekly injection of corticosteroids directly into tumor with triamcinolone acetonide can give dramatic results. This should be given weekly.
- **Calcitonin**—systemic administration of salmon calcitonin can lead to resolution of lesion. It should be given daily for 12 months as intradermal injection or nasal spray.
- **Interferon alfa**—this is also given in some cases of central giant cell granuloma.
- **Surgical**—partial resection should be done in case of aggressive tumor.

Paget's Disease

It is also called as '*osteitis deformans*'. It was discovered in 1877 by Sir James Paget. It fondly refers to as '*collage of matrix madness*'. There is abnormal resorption and apposition of bone in one or more bones. The disease is initiated by an intense wave of osteolytic activity with resorption of normal bone resulting in irregularly shaped resorption cavity followed by vigorous osteoblastic activity forming woven bone after variable period.

Etiology

- **Inflammatory**—initially it is thought to be inflammatory disease, but later on this cause is ruled out.
- **Circulatory disturbance**—the bone in Paget's disease is excessively vascular and it has been suggested that vessels are similar to arteriovenous aneurysms.
- **Slow virus theory**—slow viruses are those viruses which take a long time for incubation. The possibility of an infective, viral Etiology for Paget's disease is suggested by ultra-structural demonstration of intra-nuclear inclusions in abnormal osteoclast.
- **Genetic and environmental factors**—genetic and environmental factors appear to be important. It is transmitted as autosomal dominant trait with genetic heterogeneity.
- **Connective tissue factors**—it may be a disorder of connective tissue biosynthesis.
- **Others**—vasculitis, trauma, hormonal imbalance, degenerative neurologic disorders.

Clinical Features

- **Geographical prevalence**—it is seen most frequently in Britain and less frequently in North America and Western Europe.
- **Age and sex**—predominantly in patients over 40 years of age with a slight predilection for men. Male to female ratio is 2:1.

- **Sites**—it is prone to occur in the axial skeleton especially the skull, femur, sacrum and pelvis. It is usually polyostotic.
- **Symptoms**
- **Skull enlargement**—first complaint is that patient needs to buy a hat of larger size because of skull enlargement.
- **Pain**—bone pain is a consistent symptom and most often directed towards weight bearing areas. The patients may have ill defined neuralgic pain as a result of restriction of foramina and canals, which occurs due to pressure created by mass on structures passing through the foramina.
- **Deafness**—deafness due to involvement of the petrous portion of temporal bone with compression of cochlear nerve in the foramen.
- **Neurological symptoms**—there may be mental disturbance, and dizziness.
- **Signs**—bowing of legs, curvature of spine and enlargement of skull. The involved bones are warm to touch because of increased vascularity and are prone to fracture.
- **Simian appearance (likes an apes or monkey)**—due to grotesque facial appearance along with waddling gait and short stature patient has got simian appearance.
- **Waddling (short step) gait**—broadening and flattening of the chest and spinal curvature. The patient assumes waddling gait.
- **Complication**—skeletal deformities, fracture of limbs, compression of spine, and occurrence of giant cell lesion. Another complication includes renal calculi, salivary calculi and hypercalcemia.

Oral Manifestations

- **Sites**—maxilla is involved three times more commonly than mandible. It is bilaterally symmetrical in the involved jaw.
- **Symptoms**—movement and migration of affected teeth occurs. Due to migration patient may noticed malocclusion. In case of edentulous patient as alveolar ridge becomes enlarged patient complaint of poor fit of denture.
- **Signs**—increase in alveolar width associated with flattening of palate when maxilla is involved (**Fig. 34-18**).
- **Appearance**—as the disease progresses, the mouth may remain open exposing the teeth as the lips are too small to cover the enlarged jaws.
- **Extraction sites**—extraction sites heal slowly and incidences of osteomyelitis are higher. Extraction may be further complicated by excessive bleeding from highly vascular abnormal bones in the lytic phase of disease.
- **Complications**—osteogenic sarcoma, osteomyelitis, pathological fracture and facial paralysis. Sarcoma is

Fig. 34-18: Patient of fibrous dysplasia showing increases width of alveolar ridge (Courtesy Dr Bande).

suspected in cases that experience a marked increase in intensity of bone pain or other symptoms and show marked increased in alkaline phosphatase.

- **Prognosis**—it is poor in patients showing development of osteogenic sarcoma in Paget's disease.

Radiographic Features

Early radiolucent stage

- **Appearance**—inferior cortex of mandible may appear osteoporotic and possess a laminated structure.
- **Trabecular arrangement**—bone pattern in which trabeculae though reduced in number, run linearly in the direction of length of bone and have few intersections between them. This appearance is most commonly seen posterior to bicuspid. In the anterior region, the bony trabeculae are coarse and relatively straighter than normal, but they intersect producing bone spaces that are larger than normal. Coarse and sparse trabeculae, sometimes, tend to converge towards the midline of mandible which is highly suggestive of Paget's disease. In this stage, inferior border of the mandible may appear osteoporotic and have a laminated structure.
- **Effect on root**—root resorption is common.
- **Osteoporosis circumscripta**—in the skull, early lytic lesion may be seen as discrete radiolucent areas termed as *osteoporosis circumscripta*. The margins are somewhat irregular. There is appearance of denser bone around the radiolucency.
- **Lincoln's sign or black beard**—this sign is present in bone Scintigraphy. Bone scan may demonstrate marked uptake throughout the entire mandible. This is called as Lincoln's sign or black beard.

Granular or ground glass appearance

- **Radiopaque patches**—there are rounded radiopaque patches of abnormal bone of greater density within the

radiolucent bone, within which it is not possible to see any actual bone structure.

- **Size**—these densities may be a centimeter large or only a few millimeters in diameter.

A dense, more radiopaque stage

- **Cotton wool appearance**—in later stages, rounded radiopaque patches of abnormal bone are often seen giving an impression of cotton wool. As the fully opacified area becomes more numerous and enlarged, they tend to coalesce. The bone is denser and appears whiter on the radiograph.
- **Enlargement of bone**—it enlarges the affected bone and it may be four times than their normal thickness on lateral radiographs. In some cases there is irregular enlargement of alveolar processes which become prominent and bulge.
- **Prognathism of mandible**—due to deposition of bone in mandible, it may appear prognathic.
- **Effect of maxillary sinus**—lesions in maxillary area may encroach the maxillary sinus and obliterate it.
- **Hypercementosis**—it may be produced on one or more teeth (**Fig. 34-19**).
- **Ankylosis of teeth**—it may obliterate the areas of lamina dura and periodontal ligament space around both, normal and hypercementosed roots resulting in ankylosis of teeth.
- **Osteogenic sarcoma**—development of osteogenic sarcoma may produce frank dissolution or destruction of bone. In it, there is loss of continuity of the margins on the one side of the lesion which is suggestive of the destruction. Also in some cases, soft tissue shadow is seen.

Diagnosis

- **Clinical diagnosis**—in this simian appearance, enlargement of skull, bowing of leg and bone pain may give clue to the diagnosis.

Fig. 34-19: Hypercementosis of teeth in the mandibular teeth (Courtesy Dr Bhaskar Patle).

- *Radiological diagnosis*—cotton wool appearance, Lincoln sign, and osteoporosis circumscripta are diagnostic features of Paget's disease.
- *Laboratory diagnosis*—serum alkaline phosphatase level is increased, occasionally, attaining the level of 200 or more KA units. Serum calcium and serum phosphorus levels are within normal limits. Urinary hydroxyproline levels increase from normal levels of 440 mg/24 hours to 1 gm/24 hours. Histologically there is appearance of mosaic bone.

Differential Diagnosis

Early stage—radiolucent appearance

- *Giant cell lesions of hyperparathyroidism*—in Paget's disease, there is an increase in serum alkaline phosphatase only whereas in Giant cell lesions of hyperparathyroidism there is elevation of serum alkaline phosphatase as well as serum calcium levels with decrease in serum phosphate levels. Also in case of hyperparathyroidism, there is overall radiolucency.
- *Osteoporosis*—in early stages, it may be confused with Paget's disease but if the bony area in question is pathologically enlarged and if straight linear trabeculae are seen in the affected bone parallel to the long axis, osteoporosis is ruled out. Blood chemistry is normal.
- *Osteomalacia*—pseudofractures are common in cases of osteomalacia. Serum calcium and serum phosphorus levels are decreased in osteomalacia whereas in Paget's disease, they are normal.
- *Multiple myeloma*—it causes painful enlargement of the jaws and shows typical radiolucent punched out lesions on the skull radiograph. Positive test for Bence Jones proteins.

Second stage—mixed radiolucent radiopaque appearance

- *Osteogenic sarcoma*—it occurs in a younger age group (10-40) than that of Paget's disease and it shows a variety of radiographic appearance i.e. sunburst and Codman's triangle.
- *Cementifying and ossifying fibroma*—it is predominately seen in the younger age group and they show well defined margins in contrast to that of Paget's disease which is diffuse.
- *Fibrous dysplasia*—age difference, Paget's disease spreads more diffusely, seen bilaterally, cotton wool appearance. Maxillary sinus is reduced in size in the case of fibrous dysplasia but in the case of Paget's disease, it fails to reduce the air space.
- *Osteoblastic metastatic carcinoma*—it will give a history of parent tumor or show signs and symptoms of primary tumor.
- *Ossifying sub-periosteal hematoma*—it can be excluded if the patient gives a recent history of trauma and in addition it is seen in patients less than 15 years of age.

- *Ossifying post surgical defect*—it will give a history of surgery.
- *Chronic osteomyelitis*—it is rare in maxilla.
- *Chondroma and chondrosarcoma*—it produces pain, which is not a feature of Paget's disease.

Advanced stage—purely radiopaque

- *Florid osseous dysplasia*—it is confined to jaw bone and hypercementosis is present.
- *Osteosclerosis*—small and confined to jaw bone.
- *Tori*—same as above.
- *Osteoma*—same as above.

Management

- *Medical*
 - *Calcitonin*—a parathyroid hormone antagonist produced by the thyroid gland, suppresses bone resorption and also relieves pain and decrease serum alkaline.
 - *Sodium phosphate*—it retards bone resorption.
 - *Bisphosphonates*—they have also been used, since they inhibit bone resorption as well as mineralization. Bisphosphonates which are used are etidronate, pamidronate, alendronate, tiludronate or risedronate.
 - *Mithramycin*—it is considered as a second line agent due to its toxicity; is cytotoxic to osteoclasts.
 - *Plicamycin*—it inhibits osteoclastic activity
- *Surgery*—surgical approach for esthetics correction should be carried out.
- *Radiation*—in some cases radiation therapy can be useful.

Giant Cell Lesions of Hyperparathyroidism

It is discussed in the Chapter 36: Endocrine Disorders.

Fibro-osseous Lesions of Periodontal Origin

Periapical Cemental Dysplasia

It is described in Chapter 14: Odontogenic Tumor of Jaw.

Florid Osseous Dysplasia

It is also called as 'chronic sclerosing osteomyelitis', 'sclerosing osteitis', 'multiple enostosis' and 'sclerotic cemental masses'. It is considered to be a widespread form of periapical dysplasia. It is derived from the cells in or near the periodontal ligament space.

Robinson defined it as an abnormal reaction of bone to irritation or stimulation and the term florid osseous dysplasia includes chronic diffuse sclerosing osteomyelitis

and sclerotic cemental masses. It is inherited as an autosomal dominant trait.

In florid osseous dysplasia, the normal bone is replaced by fibrous tissue and mineralized structure like cementum, bone or both.

Clinical Features

- **Age and sex**—females are exclusively affected. Most common age is middle age, with a mean age 42 years with predilection for blacks.
- **Sites**—the lesion is restricted to the jaw bone with mandible being most commonly affected.
- **Symptoms**—there is a painless expansion of the alveolar process of mandible. Patients may complain of intermittent poorly localized pain in the affected bone area, with or without an associated bony swelling.
- **Signs**—if the lesion secondarily infected features of osteomyelitis may develop. Mucosal ulceration with fistulous tract may be present. Teeth in the involved bone are vital.

Radiographic Features

- **Location**—lesions of florid osseous dysplasia present bilaterally in both the jaws. Lesions occur above the inferior alveolar nerve canal. It involves all four quadrants.
- **Radiodensity**—it varies from an equal mixture of radiolucent and radiopaque region to almost complete radiopaque.
- **Size**—individual lesions do not exceed 2-3 cm in diameter. The lesions may extend into the mandibular ramus or into the maxillary sinus.
- **Margins**—margins are fairly regular and well defined. Each lesion is surrounded by a radiolucent capsule and a cortical rim.
- **Radiolucent stage**—in this stage, well defined radiolucent area are superimposed over the apical area of adjacent tooth.
- **Mixed stage**—in this stage radiolucent cavity, partially filled with one or more dense radiopaque masses. As lesions mature, the radiopacities increase. This stage also shows *target appearance* with central calcified masses in the radiolucent lesion.
- **Radiopaque stage**—this shows multiple radiopacity continuous with the surrounding bone, but they were separated from adjacent teeth periodontal ligament space. In this stage *cotton wool appearance* (lobular or lump shaped and soft radiopaque characters like that of cotton wool) is seen.
- **Active hypercementosis**—hypercementosis of tooth in the affected area is seen. There is an also wide periodontal ligament space.

Differential Diagnosis

- **Paget's disease**—no radiolucent capsule and increased serum alkaline phosphatase levels. Paget's disease affects entire mandible while florid osseous dysplasia occur above the inferior alveolar canal.
- **Chronic sclerosing osteomyelitis**—signs of infection is present in osteomyelitis.
- **Osteopetrosis**—profuse thickening of the skull base or calvarium and diffuse bony radiopacities. It will cause enlargement of bone, which is not a feature of florid osseous dysplasia.

Diagnosis

- **Clinical diagnosis**—painless expansion in four quadrant of jaw will give clue to diagnosis.
- **Radiological diagnosis**—radiopaque, mixed lesion in all four quadrants with active hypercementosis will diagnose this condition.

Management

- **Effective oral hygiene**—if teeth present effective oral hygiene should be maintained since with this disease, patients exhibit poor healing and osteomyelitis may develop after tooth loss.
- **Recontouring**—patients with more severe form of the disease has superficial lesions which are located near the crest of alveolar ridge, these may require recontouring to accommodate the denture or to prevent ulceration.

Cemento-ossifying Fibroma

This is the terminology used for *cementifying fibroma* and *ossifying fibroma*. Cemento-ossifying fibroma is a benign fibro-osseous neoplasm. The description of the ossifying fibroma of the jaws was first given by Montgomery in 1927. It is a benign neoplasm that is osteogenic (non-odontogenic), well defined and rarely encapsulated, consisting of fibrous tissue with variable amounts of mineralized material similar to bone and/ or cementum. Chromosomal abnormalities have been identified in the ossifying fibroma; however, the molecular mechanisms that causes the development of this tumor remain unknown.

Nomenclature

The previous nomenclature of ossifying fibroma or cementifying fibroma was based upon the histopathology which displayed predominantly bone like or cementum like tissue, characterized by osteoblasts and cementoblasts respectively. This terminology was first used by Hamner, but is of little practical value because of the range of the behavior of these lesions with identical histopathological appearance. Furthermore many of them contained both bone and cementum like elements. Therefore these lesions

appear to represent points on a spectrum of histological appearances extending from bone to cementum. This indicates that they probably originated from the same progenitor cell, which Waldron suggested is to be found within the periodontium.

Taking account of the wide range of histological manifestation, the WHO in 1992 revised its nomenclature to refer to the separate lesions of the cementifying fibroma and ossifying fibroma as a single entity termed 'cemento-ossifying fibroma'.

Clinical Features

- *Age and sex distribution*—it predominantly occurs in females in third or fourth decades of life.
- *Bones affected*—it can arise from any part of the facial skeleton and skull with over 70% of cases arising in the head and neck region. Cemento-ossifying fibromas ostensibly do not occur outside the craniofacial complex. Although it has been principally found in the jaws, it has also been reported in the orbitofrontal bone, nasopharynx, paranasal sinuses and skull base. Most lesions arise in the tooth bearing areas of the mandible and maxilla (**Fig. 34-20**). It mostly occurs in molar and premolar mandibular area above the inferior alveolar canal. In the maxilla, it occurs most often in the canine fossa and zygomatic arch area.
- *Symptoms*—there is occasional facial asymmetry is seen in some of the cases. When in maxilla, symptoms may include nasal stuffiness and epiphora on the affected side.
- *Signs*—there may be associated exophthalmos, with visual disturbances, depending on the extent of compression of its orbital content by the tumor.
- *Giant ossifying fibroma*—large lesions increasing in size to over 80 mm in their greatest diameter have been termed 'giant ossifying fibroma' (**Fig. 34-21**).
- *Teeth*—the lesion is slow growing and in some cases, there is displacement of teeth.
- *Cortex*—bony cortex and covering mucosa remain intact.

Fig. 34-20: Cemento-ossifying fibroma involving maxillary lesion (Courtesy Dr Bhaskar Patle).

Fig. 34-21: Giant ossifying fibroma showing lesion over 80 mm in diameter.

- *Progress*—the lesion may be slow growing initially, with a rapid increase in size in a relatively short time.
- *Maxillary sinus*—if sinus is affected it may fill the sinus completely and expands the sinus wall.

Radiographic Features

- *Periphery*—the borders of cemento-ossifying fibroma lesions usually are well defined. A thin radiolucent line, representing a fibrous capsule, may separate it from surrounding bone. Sometimes, the bone next to the lesion develops a sclerotic border.
- *Internal structure*—it is a mixed radiolucent/ radiopaque density with a pattern that depends on the amount and form of the manufactured calcified material. In the early stages solitary cyst-like osteolytic lesions without periosteal reaction are seen. In some instances, the internal structure may appear almost totally radiolucent with just a tint of calcified material. In the type that mainly contains abnormal bone, the pattern may be similar to that seen in fibrous dysplasia, or a wispy (similar to stretched tufts of cotton) or flocculent pattern (similar to large, heavy snowflakes) may be seen (**Fig. 34-22**). Lesions that produce more cementum like material may contain solid, amorphous radiopacities (cementicles) similar to those seen in cemental dysplasia.
- *Effect on surrounding structure*—cemento-ossifying fibroma can be distinguished from the previously mentioned bone dysplasia by its tumor like behavior. This is reflected in growth of the lesion, which tends to be concentric within medullary part of bone with outward expansion approximately equal in all directions. These neoplasms have propensity for osseous cortical expansion and encroachment on contiguous structures. A significant point is that the outer cortical plate, although displaced and thinned remains intact. In the mandible, bowing or erosion of the inferior cortex is seen. It results in displacement of the inferior alveolar canal. The cemento-ossifying fibroma lesion can grow into and occupy the entire maxillary sinus, expanding its walls outward; however, a bony partition always

Fig. 34-22: Cemento-ossifying fibroma presenting a flocculent pattern.

exists between the internal aspect of the remaining sinus and the tumor. In the orbit they may displace the globe. Expanding lesion can cause displacement of the teeth. The lamina dura of involved teeth usually is missing and resorption of teeth may occur.

Diagnosis

- *Clinical diagnosis*—not so specific. Facial asymmetry is seen.
- *Radiological diagnosis*—mixed radiopaque radiolucent lesion seen with sclerotic border. Displacement of teeth can also be seen
- *Laboratory diagnosis*—large number of fibroblasts, with flat elongated nuclei is present within the network of interlacing collagen fibers. Chinese letter shaped islands of bone or calcification is also seen.

Differential Diagnosis

Early radiolucent stage

- *Post extraction socket and residual cyst*—history of extraction and history of surgery
- *Primordial cyst*—it is always associated with a missing permanent tooth which is not a case with cementifying/ossifying/cemento-ossifying fibroma.
- *Ameloblastoma*—it occurs in posterior most part of the mandible and is accompanied by paresthesia of the lip. It often shows a multilocular appearance.
- *Periapical cemental dysplasia*—it occurs at the apices of vital teeth. However, they affect an older age group than cementifying/ossifying/cemento-ossifying fibroma and have a predilection for the lower incisor region whereas cementifying/ossifying/cemento-ossifying fibroma often occurs in premolar-molar region.

- *Adenomatoid odontogenic tumor*—usually associated with impacted maxillary canines in a younger patient and borders are regular.

Mixed radiopaque radiolucent lesion

- *Calcifying epithelial odontogenic tumor*—it occurs in posterior body and ramus of mandible.
- *Osteoid osteoma*—it is more common in males under 30 years of age and is not frequently seen in jaws, whereas, cemento-ossifying fibromas are tumors predominantly of jaws and are common in females in their third or fourth decade of life. It causes pain that predominantly occurs in night time, which is a distinguishing feature as cemento-ossifying fibroma is mostly an asymptomatic lesion. Radiographically, it appears as a well-circumscribed radiolucent area with sclerotic halo in initial lesions. In more mature lesions, the central radiolucency may have a radiopaque foci representing abnormal bone.
- *Osteoblastoma*—it is rare lesion in the head and neck. Histologically, it exhibits bone to stroma ratio of one to one, with frequent fibroblastic atypia and occasional mitotic figures, features which help in differentiation from cemento-ossifying fibroma when radiographic features are confusing.
- *Osteosarcoma*—it should be differentiated on the basis of malignant characteristics of the tumor such as aggressive growth, destruction of cortical bone, invasion into surrounding soft tissues and along the periodontal ligament, whereas, cemento-ossifying fibromas has a benign behavior.
- *Benign cementoblastoma*—it occurs in second and third decades of life in posterior mandibular region. It is characteristically attached to the part of the root with frequent root resorption. Cemento-ossifying fibroma is not attached to the root although it may resorb the roots. Radiographically it is an opaque lesion with a radiolucent halo. Histological study reveals agglomerates of material similar to cementum and connective tissue stroma. Many of the cemental trabeculae are surrounded by cementoblasts. Clinically, it may sometimes manifest as a pain and swelling unlike cemento-ossifying fibroma, which is usually not associated with pain.
- *Juvenile ossifying fibroma*—Contrary to cemento-ossifying fibroma, which occurs mostly in third and fourth decades of life, juvenile ossifying fibroma appears in patients under 15 years of age. Cemento-ossifying fibroma most commonly affects mandible predominantly premolar-molar region, whereas, juvenile ossifying fibroma affects predominantly maxilla. It has a rapid growth that frequently erodes the surrounding bones. Though the radiographic appearance of this entity has similarities to cemento-ossifying fibromas, it shows differences histopathologically. Histological picture is characterized

by a cellular vascular stroma with variable amount of giant cells, scarce collagen and small ossicles surrounded by an osteoid halo. They do not have fibrous capsule.

- *Metastatic osteoblastic carcinoma and chondrosarcoma*—ill-defined borders with periosteal bone formation. It is rapidly growing, as compared to cementifying/ossifying/cemento-ossifying fibroma which has well defined margins and separated from normal adjacent bone by a radiolucent fibrous capsule.
- *Periapical cemental dysplasia*—as described in differential diagnosis of periapical cemental dysplasia.
- *Paget's disease*—cotton wool appearance and enlargement of affected bone.
- *Fibrous dysplasia*—homogeneous radiopaque area with an internal architecture that is evenly granular and obliterates normal bone marrow space. Borders are ill defined and gradually blend into surrounding normal bone. Root resorption is rare. It is more commonly found in mandible, with an equal sex distribution.

Mature stage

- *Periapical spherical type of hypercementosis*—it is attached to a part of root and is separated from the periapical bone by a radiolucent periodontal ligament space which surrounds the entire root.
- *Condensing osteitis*—it can be ruled out because it occurs at the periapex of a non-vital tooth. It does not have a radiolucent rim which is seen in fibro-osseous lesions.
- *Periapical idiopathic osteosclerosis*—it occurs in the periapical region of vital teeth. Cementifying/ossifying/cemento-ossifying fibroma however is smoothly contoured and almost round and ovoid, whereas periapical idiopathic osteosclerosis is usually quite irregular in shape and also there is absence of a radiolucent rim.
- *Complex odontoma*—density is not uniform and also it seldom occur periapically.

Management

- *Enucleation*—small, clinical encapsulated lesions are treated by conservatively enucleation.
- *Resection*—it is recommended if there is involvement of inferior border, extension into maxillary sinus occurs.

Peripheral Ossifying Fibroma

It presents as a tumor like growth of the oral soft tissues and is often associated with sharp teeth, rough restoration, and ill-fitting dentures.

Clinical Features

- Even though cemento-ossifying fibroma is considered as an intraosseous lesion, affects the gum and soft tissue have also been described.

- An excrescent, ulcerated, painful, friable lesion that bleeds when touched could be observed.
- Clinically, they usually present as reddish brown, firm, pedunculated or sessile masses at the site of trauma (Fig. 34-23).
- The overlying mucosa may be ulcerated and this may draw the patient's attention to the lesion. If the patient is dentate, the adjacent teeth may be mobile.

Fig. 34-23: Peripheral ossifying fibroma (Courtesy Dr Soni).

Radiographic Features

- In edentulous patients, there may appear to be some superficial erosion of the underlying bone on radiographs.
- Intra-oral films taken with low penetration may show varying amounts of calcification within the lesion.

Diagnosis

- *Clinical diagnosis*—not so specific.
- *Radiological diagnosis*—erosion of underlying bone below the lesion with calcification will give clue to diagnosis.

Other Lesions of Bone

Osteoporosis

There is reduction in the inorganic constituent of bone. There is abnormal persistence of calcified cartilage. Spongy portion of affected bone ultimately becomes a solid block of calcified cartilage leaving inadequate space for hemopoiesis. It is characterized by low bone mass and micro-architectural bone fragility. It is usually rarefaction of bone resulting from deficiency of bone matrix rather than deficit mineral.

Types

- *Primary* (associated with aging).
- *Secondary* (reduction of histologically normal bone that has been accelerated by abnormal or iatrogenic circumstance such as corticosteroid or heparin therapy or condition such as malnutrition and scurvy).

Mechanism of Bone Loss

- *Imbalance between bone resorption and bone formation*—it is caused by imbalance between bone resorption and bone formation with an exaggeration of resorption, reduction in bone formation or combination of both.
- *Postmenopausal and senile*—it occurs due to overall decrease in anabolic hormones (estrogen) in postmenopausal women. There may be lag in formation of bone and since bone resorption is continued, it results in osteoporosis. After the age of 60 years, generalized atrophy of bone occur (senile osteoporosis). Senile osteoporosis is caused by decrease in calcium absorption, vitamin D absorption and metabolism with age, which in turn decreases the anabolic hormones, muscular proteins and flow of blood to bone. By virtue of this condition, bone resorption occurs. Another cause of bone resorption in adults is that, in elderly person altered hormonal function lead to formation of small thrombi which plug small vessels in bone and cause loss of bone vitality and hence resorption.
- *Cushing's syndrome*—the symptoms are caused by an increased output of glucocorticosteroids, especially cortisol. The excess cortisol acts to produce osteoporosis by two ways:
 - It contributes to the degradation of proteins and severely limits the formation of bone matrix by reducing the amount that each osteoblast synthesizes.
 - It promotes the formation of osteoclasts from the osteogenic undifferentiated cells and thus enhances bone resorption.
- *Drug-induced osteoporosis*—prolonged administration of cortisol and cortisone show Cushing's like syndrome and cause osteoporosis in the same way as that in Cushing's syndrome. Contraceptive drug can also cause osteoporosis; as after administration of contraceptive drug, there is increase in level of cortisol. Combination of these two compounds leads to production of abnormal megakaryocytes, which in turn leads to formation of abnormal sticky platelets. These sticky platelets fuse to form thrombi which occlude small vessels in the tissue due to which the bone dies and get resorbed.
- *Malnutrition state*—sufficient protein must be absorbed from intestine to supply constant need for matrix formation. Deficiency causes osteoporosis and may result from protein poor diet or from GIT disturbances

such as colitis, regional arteritis. Vitamin C deficiency may weaken sinusoidal vessel walls in medullary bone which tend to dilate and rupture, resulting in pooling of blood and hypoxia, which leads to loss of vitality and removal of bone by physiologic osteoclast.

- *Stress*—there is interaction between the progesterone compounds and increased level of cortisol by stress, leading to formation of multiple small thrombi. The thrombi occlude small vessels of osseous tissue, which results in death and resorption of bone, leading to osteoporosis.
- *Thyrotoxic osteoporosis*—it is usually seen in children with hyperthyroidism. Thyroxin mediates the action of cortisol on bone and an excess of thyroxin results in a more efficient utilization of steroids. Thus there is increased resorption.
- *Osteoporosis and oral bone loss*—a decrease in bone mass from unbalanced system in which there is decreased bone formation or increased bone resorption, is designated as skeletal osteopenia. The designation of osteoporosis being given when the changes in bones are accompanied by pain, deformity or fracture. It is also defined as too little calcified bone and as a condition when the concentration of bone (mineral) lies more than two standard deviation below the corresponding values for the age, when matched with normal value.

Clinical Features

- *Age*—either present at birth (congenital) or developed in early life (infantile).
- *Fracture*—bones are fragile and susceptible to fracture. These fractures typically affect the forearm (Colle's fracture), spine (vertebral fracture) and hip (femur fracture).
- *Congenita form* inherited as an autosomal recessive disorder is invariably fatal in early life due to massive hemorrhage, anemia and rampant bone infections occurring due to progressive loss of bone marrow and their cellular products.
- *Percussion*—percussion over the affected vertebrae is painful.
- *Symptoms*—osteoporotic patient may notice gradual loss of height due to shortening of trunk. In advanced cases, clinical onset is often characterized by attack of severe pain which is aggravated by movements and occurs after trauma.
- *Osteomyelitis*—it may occur due to relatively avascular and there may be bone pain.

Oral Manifestations

- *Osteomyelitis*—marked predilection for development of osteomyelitis.

- *Jaws*—fracture of jaws during tooth extraction.
- *Enamel hypoplasia*—enamel hypoplasia. Microscopic dentinal defect.
- *Teeth*—arrested root development, retardation of tooth eruption. Delayed eruption and early loss of teeth missing teeth and malformed teeth. Teeth are poorly calcified and are prone to caries.

Radiographic Features

- *Appearance*—typical wedge appearance of affected vertebrae, on a lateral radiograph.
- *Internal structure*—reduction in number of trabeculae is least evident in the alveolar process. Persistent trabeculae tend to occur along planes of bone stress. Trabeculae may be arranged in a radial manner, with wide spaces in between.
- *Cortex*—reduced density and thinning of cortical boundaries, such as inferior mandibular cortex (**Figs 34-24 and 34-25**).
- *Lamina dura*—the lamina dura surrounding the teeth may appear thinner than normal
- Anatomic shadows such as the nasal fossa and maxillary sinus are less distinct.

Fig. 34-24: Osteoporosis presenting as decrease in density of bone (Courtesy Dr Parate).

Fig. 34-25: Senile osteoporosis showing reduce density of the bone.

Diagnosis

- *Clinical diagnosis*—osteomyelitis of the jaw with fragile bone and fracture of bone will give clue to the diagnosis.
- *Radiological diagnosis*—wedge shaped appearance of the vertebrae with reduce density of bone in the jaw.
- *Laboratory diagnosis*—there is anemia, hepatomegaly, decrease RBC count and increase serum phosphatase levels. Biopsy shows lack of physiologic bone resorption. Osteoblasts are prominent but osteoclasts are seldom found. Trabeculae are in disorder arrangement.

Differential Diagnosis

- *Infantile cortical hyperostosis*—positive history of highly specific soft tissue and bony abnormalities are found. Sites of involvement limited to few bones. New bone is subperiosteal and continuous to inferior border.

Management

- *Life style changes*—good nutrition and regular exercise helps to prevent osteoporosis. Person should be asked to stop smoking and alcohol.
- *Calcium supplement*—they are widely used as an adjunct to other treatment in the prevention and treatment of osteoporosis. Recommended dose is 1000 mg/day.
- *Anabolic steroids* such as stanozolol, vitamin D and vitamin D active metabolites are also used.
- *Bisphosphonates*—new drug for systemic osteophonates are under evaluation and this includes bisphosphonates. These are synthetics analogue of pyrophosphate that absorb on to bone surface and become incorporated into the bone matrix. When the bone contains bisphosphonates is ingested by resorbing osteoclasts, the drug released within cell in high concentration and thus exerts a toxic effect, leading to cell death and inhibits the bone resorption.
- *Hormone replacement therapy*—hormone replacement therapy with estrogen is the treatment of choice of prevention of osteoporosis. Progesterone should be added to estrogen in women with intact uterus, to reduce the risk of endometrial carcinoma.
- *Alendronate* 110 mg daily with calcium supplement is also effective. Etidronate 400 mg daily for 2 weeks followed by 13 weeks calcium supplement is also useful.
- *Calcitonin injection*—injection of *calcitonin* to reduce bone resorption can be given. But it is rarely used due to side effects as hot flushes and nausea.
- *Grafting procedures* to rebuild the residual ridge and implants to stabilize dentures are being used in advanced cases of bone loss.
- *Prevention of bone loss*—oral bone loss can be prevented by plaque control, removal of local etiologic factors and use of antibiotics in case of early onset periodontitis.

Infantile Cortical Hyperostosis

It is also called as 'Caffey's disease', 'Caffey-Silverman syndrome'. It was first described in detail in 1945. It is characterized by unusual cortical thickening of certain bones and it occurs in two forms i.e. autosomal dominant form and sporadic form.

Etiology

- *Embryonic osteodysgenesis*—it may be an embryonic osteodysgenesis consequent to local defect in blood supply to the area.
- *Inherited defect*—Inherited defects of arterioles supplying the affected part results in hypoxia producing focal necrosis of overlying soft tissue and periosteal proliferation.
- *Allergy* as the basis of disease, edema and inflammation producing periosteal elevation and subsequent deposition of calcium.
- *Hereditary* being an autosomal dominant trait.

Clinical Features

- *Age and sex*—it is equal in males and females, with average onset at 9 weeks of age, with most of the cases arising before 6 months.
- *Sites*—bones commonly affected are mandible, clavicle, scapula, frontal bone and ulna. There is bilateral involvement in every case. Of all these bone clavicle and mandible are the most common sites.
- *Symptoms*—infants will develop fever and become hyper-irritable.
- *Signs*—soft tissue swellings have a sudden onset, especially in the facial area and early in disease, they may be warm and tender. Swelling is devoid of clinical signs of inflammation on the overlying skin. Swelling disappears slowly, but may suddenly recur at the same place or new site may be involved.
- *Others feature*—other features are pseudo-paralysis, pleurisy and dysphasia.

Oral Manifestations

- *Sites*—mandible is one of the commonest bones affected in infantile cortical hyperostosis.
- *Symptoms*—patient may have malocclusion and enamel hypoplasia may be present.
- *Signs*—residual asymmetric deformity of mandible, usually in the angle and ramus area.

Radiographic Features

- *Incidence*—only after swelling have subsided and ceased to be tender, many bone changes occur.

- *Cortex*—thickening of inferior cortex caused by new bone formation deep to the periosteum takes place.
- *Mandible*—overall enlargement of body of mandible with homogeneously increased density throughout.
- *Laminated appearance*—occasionally, the new bone may be laid down in layers giving the inferior cortex a laminated appearance.
- *Surface*—the surface of new bone may be smooth in some cases, while irregular in some cases.
- *Lamina dura*—the lamina dura and cortices of tooth follicle are normal.

Diagnosis

- *Clinical diagnosis*—infant with fever, soft tissue swelling, with swelling in the jaw will give clue to the diagnosis.
- *Radiological diagnosis*—thickening of cortex with laminated appearance.
- *Laboratory diagnosis*—anemia, leukocytosis, elevated erythrocyte sedimentation rate, monocytosis and increased serum alkaline phosphatase levels.

Differential Diagnosis

- *Callus formation*—unilateral or at least asymmetrical, when seen bilaterally.
- *Osteoma*—rarely discovered in a younger age.
- *Cherubism*—multilocular expansile radiolucency with no cortical thickening.
- *Osteoporosis*—in infantile cortical hyperostosis, abnormal bone production is subperiosteal while in osteoporosis, it is cancellous.
- *Osteomyelitis*—osteomyelitis of jaw may be associated with laying down of much subperiosteal new bone. But infantile cortical hyperostosis occurs within 6 months of life, as compared to osteomyelitis which occurs very unusually below 6 months of life. In osteomyelitis, whole of the mandible is not involved.
- *Periostitis of jaw*—it is apparently unilaterally involved and is localized. It is possible to see underlying cause of the condition. Laminated structure in periostitis is visible only at the inferior margins as compared to infantile cortical hyperostosis which is visible all over the bony surface of jaw.
- *Fibrous dysplasia*—Caffey's disease represent the changes added to be the bone, while fibrous dysplasia is an abnormality within the bone.
- *Hypovitaminosis A*—it produce the condition called as cortical hyperostosis. But it usually affects metacarpal bone and occurs over the age of 1 year, while infantile cortical hyperostosis occurs below 6 months and mandible is commonly affected.

Management

- There is no specific treatment for this disease.

Osteopetrosis

It is also called as 'Marble bone disease', 'Albers-Schonberg disease', 'osteosclerosis fragilis generalisata'.

It is a rare disorders characterized by an increase in density of bones, which becomes hard and brittle. This is a result of endosteal bone production with a lack of concomitant bone resorption and remodeling. The reason for this is that there is lack of normal osteoclast formation.

Types

- *Infantile osteopetrosis or malignant osteopetrosis*—it is a malignant childhood condition with a severe form showing severe skeletal and neurological signs. Those affected rarely live beyond the age of 2 years. It is autosomal recessive.
- *Intermediate osteopetrosis*—this is less severe form of osteopetrosis with fracture occurring at the end of first decade. It is autosomal recessive.
- *Transient osteopetrosis*—it shows radiographic evidence of diffuse sclerosis and it resolves without therapy. It is autosomal recessive.
- *Adult's osteopetrosis or benign osteopetrosis*—it is an autosomal dominant form. The adult form is characterized by predominantly skeletal signs with long having little or no defect.

Clinical Features

- *Age*—it can occur in infant and some cases are diagnosed later in life.
- *Skeletal features*—almost every one has a varying degree of poor skeletal development, if the disease appears early in life. Subsequent skeletal deformities occur later due to bending of the long bones and improper healing after pathological fractures.
- *Symptoms*—as a result of continuous bone deposition and lack of bone resorption, the foramina of cranial nerves are constricted, hence there is loss of hearing, disturbed vision, which diminish progressively.
- *Facial palsy*—facial nerve palsy is also seen.
- *Signs*—due to displacement of hematopoietic bone marrow, anemia ensues and the hematopoietic function is assumed by the liver, spleen and the lymph nodes resulting in hyperplasia of lymphoid tissues and hepatosplenomegaly. There is also frontal bossing, obliteration of maxillary sinus and possible hydrocephalus and mental retardation.
- *Prognosis*—prognosis of infantile osteopetrosis is very poor as compared to adult's osteopetrosis.

Oral Manifestations

- *Sites*—it is most common in mandible and occasionally, in maxilla.
- *Osteomyelitis*—osteomyelitis of jaws associated with osteopetrosis probably follows the obliteration and fibrosis of marrow is caused by reduced osseous circulation.
- *Paranasal sinus*—paranasal sinus may become readily obliterated.
- *Teeth*—there may be enamel hypoplasia, defective dentin, disturbed tooth development, small pulp and tendency towards caries.

Radiographic Features

- *Radiodensity*—there is diffuse homogeneous sclerotic appearance of all bones, within distinction between the cortex and the marrow. This type of appearance is called as marble bone appearance (Fig. 34-26).

Fig. 34-26: Homogeneous sclerotic appearance seen in marble bone disease (Courtesy Dr Ganju).

- *Skull changes*—the changes in the skull are often striking. The base of skull becomes grossly thickened and of great radiographic density. Loss of normal skull marking and structures. The dipoles are effaced, the head of patient resembles bladder of lard. There is gross thickening and increased opacity of the cranial base, with narrowing of foramina.
- *Fracture*—due to increased calcification there is increased fragility, so fractures are common.
- *Bones*—bones are shorter than normal, heavy, thick and deformed. The ends of long bone spay out.

- *Cortex*—the cortices are thickened and differentiation between them and adjacent bone is greatly lessened.
- *Internal structure*—less marked changes may produced are the increase in overall density but trabeculation may be apparent. The trabeculae may get thickened and the marrow spaces are correspondingly small.
- *Lamina dura*—the lamina dura is almost lost in the general density. Some time density is such that the roots are nearly invisible on dental radiographs.
- *Teeth*—the roots of the teeth may be obscured, partially or totally, depending upon the bone density.
- *Cortex*—the medullary cavity is replaced by bone and cortex is thickened.

Diagnosis

- *Clinical diagnosis*—hearing deformity, fracture of bone with skeletal deformity will give clue to the clinical diagnosis.
- *Radiological diagnosis*—marble bone appearance is seen which is typical of this disease.
- *Laboratory diagnosis*—red blood cell count below 1,000,000 cells per cu mm. Elevated serum acid phosphate levels have been reported in patients with benign dominant osteopetrosis. Biopsy shows prominent osteoblasts, but osteoclasts are seldom found.

Differential Diagnosis

- *Polyostotic fibrous dysplasia*—fibrous dysplasia usually involves a part of bone, rather than the complete bone. Hence, involved bone generally exhibits asymmetric enlargement.
- *Paget's disease*—it can be differentiated from osteopetrosis by its classic bones. It most often involves the skull, pelvis, vertebrae, femur, maxilla and mandible. Also, serum chemistry measurements show markedly elevated alkaline phosphate levels.
- *Sclerotic cemental masses*—have a stronger predilection for black women over 30 years of age. The most common salient feature of this disease is that only jaws are affected, radiograph of the jaws reveal radiopaque masses frequently rimmed by radiolucent borders.
- *Infantile cortical hyperostosis*—skeletal changes are subperiosteal and not endosteal. Mandible is more commonly involved.

Management

- *Bone marrow transplantation*—this is the treatment of choice in osteopetrosis patient. But to find matched donor is a difficult process.
- *Interferon gamma 1b*—if interferon gamma 1-b is given in combination with calcitrol will reduce the bone mass.

- *Other modalities*—corticosteroid, parathormone, macrophage colony stimulating factor and erythropoietin can also be given.
- *Supportive treatment*—this is given to combat infection, osteomyelitis. Antibiotics which are given in infection are fluoroquinolones and lincomycin. Hyperbaric oxygen therapy can also be given.
- *Precaution*—avoid major surgery in patients with osteopetrosis. Performing dental extraction osteopetrosis patient has a risk of osteomyelitis and jaw fracture.

Osteogenesis Imperfecta

It is also called as 'brittle bone', 'Lobstein disease'. It is a serious disease of unknown etiology. It represents a hereditary autosomal dominant trait.

Pathogenesis

There impairment of collagen maturation. Collagen is main part of bone, dentin, sclera, ligament and skin. So collagen impairment will result in change in this structure.

Types

- *Congenital or Vrolik's type*—it is present at birth.
- *Tarda or Lobstein's type*—it is recognized later in life. It is also called as osteopsathyrosis.

Clinical Features

- *Age*—many infants with this disease are stillborn or die shortly after birth.
- *Bone deformity*—patient is having bone deformity and hyper extensibility of the joint. There is also bowing of the bone (**Figs 34.27A and B**).
- *Fracture of bone*—extreme fragility and porosity of bones with an attendant proneness of fracture. Fracture heals readily but new bone is of similar imperfection. It is common for fracture to occur while the infant is walking or crawling. Hyperplastic callus formation, which may mimic osteosarcoma, take place.
- *Blue sclera*—there is occurrence of pale blue sclera which is thin; pigmented choroids show and produce the blue color (**Fig. 34-28**).
- *Signs*—there is deafness due to osteosclerosis; laxity of ligament and peculiar shape of the skull. There is also abnormal electrical reaction of muscle. Increased tendency for capillary bleeding.

Oral Manifestations

- *Dentinogenesis imperfecta*—most of the times, osteogenesis imperfecta is associated with dentinogenesis imperfecta.

A

B

Figs 34-27A and B: Patient of osteogenesis imperfecta showing bone deformity (Courtesy Dr Lambade).

- *Enamel hypoplasia*—sometimes, there is also hypoplasia of teeth. Sometimes there is class I malocclusion and greater incidence of impacted 1st and 2nd molars.
- *Deciduous teeth*—deciduous teeth are poorly calcified and semi-translucent or waxy. Appearance of teeth is faint dirty pink, half normal size, with globular crowns and relatively short roots in proportion to other dimension.
- *Malocclusion*—there is increased prevalence of malocclusion which is caused by maxillary hypoplasia.

Fig. 34-28: Blue sclera seen in patient of osteogenesis imperfecta.

Clinical Types

- *Neonatal lethal type*—it is characterized by multiple fractures in infants and the child seldom survives.
- *Severe non-lethal type*—disease is not evident until late childhood and patient shows fracture of bone with minimum trauma. Although the fractured bone heals up rapidly, considerable skeletal deformity and dwarfed stature often develop.
- *Moderate and deforming type*—it is associated with dentinogenesis imperfecta and blue sclera.
- *Mild and non-deformity type*—the patients are clinically normal, but they have increased tendency for bone fracture, due to trauma.

Radiological Features

- *Wormian bones*—patient may show wormian bone (bones in skull sutures) (Fig. 34-29).

Fig. 34-29: Wormian bone seen in osteogenesis imperfecta (Courtesy Dr Lambade).

- **Bone deformity**—there is skeletal deformities manifested by bowing of bone and fracture of bone (**Fig. 34-30**).
- **Internal structure**—the bone is osteoporotic, there is less density and trabeculae are fewer in number.
- **Appearance**—the chin is sharply pointed, as a result of softening of bone, leading to flattening of sides of the mandible.

Fig. 34-30: Bowing of bone seen in radiograph of patient with osteogenesis imperfecta (Courtesy Dr Lambade).

Diagnosis

- **Clinical diagnosis**—severe bone deformity with blue sclera are diagnostic features of osteogenesis imperfecta.
- **Radiological diagnosis**—multiple wormian bones with osteopenia will diagnose this condition.
- **Laboratory diagnosis**—bone is composed of immature spongy bone. Osteoblastic activity retarded and there is failure of fetal collagen to be transformed into mature collagen.

Management

- **Management of fracture**—management of fracture should be done in patient.
- **Management of teeth**—teeth management should be same as that is carried out in dentinogenesis imperfecta.

Pierre Robin Syndrome

It is also called as '*Robin anomalad*'. It results arrested development.

Clinical Features

- **Triad**—it is triad of cleft palate, mandibular micrognathia and glossoptosis (causes airway obstruction).

- **Bird facies**—arrested development and ensuing hypoplasia of mandible ultimately produce the characteristic bird facies (**Fig. 34-31**). Mandibular hypoplasia yields a retrognathic appearance.

Fig. 34-31: Mandibular retrognathism resulting in characteristic bird face appearance.

- **Tongue**—the retruded mandible results in posterior displacement of the tongue.
- **Cleft palate formation**—abnormal descent of tongue occurs between the palatal shelves resulting in cleft palate (**Fig. 34-32**).

Fig. 34-32: Cleft palate formation seen in patient with Pierre Robin syndrome.

- **Respiration**—there is respiratory difficulty due to failure of support of tongue musculature because of micrognathia, allowing the tongue to fall down and backwards, partially obstructing the epiglottis. Difficulty in respiration is noted from birth and it can cause asphyxiation.

- *Others*—there may be congenital heart defects, other skeletal abnormalities and ocular lesions. Mental retardation is also a common finding.

Diagnosis

- *Clinical diagnosis*—triad of cleft palate, micrognathia and glossoptosis will diagnose this condition.

Management

- *Breathing support*—breathing support and feeding assistance are necessary during infancy.
- *Surgical*—surgical closure and orthodontic treatment are indicated.

Marfan's Syndrome

It is also called as 'Marfan-Achard syndrome', 'arachnodactyly'. It is hereditary disease transmitted as autosomal dominant trait. It is basically a disease of connective tissue related to defective organization of collagen which is abnormally soluble.

Clinical Features

- *Spider finger*—excessive length of the tubular bones resulting in disproportionately long, thin extremities, the finger and toes are long, thin and tapering so that the name 'spider finger' has been applied.
- *Shape*—the shape of face and skull is characteristically long and narrow.
- *Joint*—hyperextensibility of joint with habitual dislocations, kyphosis or scoliosis and flatfoot.
- *Bilateral ectopia lentis*—it is caused by weakening or rupture of the suspensory ligaments.
- *Cardiovascular complications*—cardiovascular complications like aortic aneurysm and aortic regurgitation, valvular defects and enlargement of the heart are common.

Oral Manifestations

- *Palate*—high arched palatal vault is very prevalent.
- *Maxilla and mandible*—bifid uvula, malocclusion and multiple odontogenic cysts of maxilla and mandible.
- *Temporomandibular joint*—there may be temporomandibular dysarthrosis.

Diagnosis

- *Clinical diagnosis*—spider finger, with high arched palate, hyperextensibility of joints.

Management

There is no specific treatment for this syndrome and prognosis is good.

Down's Syndrome

It is also called as 'Trisomy 21 syndrome' and 'mongolism'. It is associated with subnormal mentality in which an extremely wide variety of anomalies and functional disorders may occur. It results from excessive chromosomal material involving all or a portion of chromosome 21. It is caused by advanced maternal age, uterine and placental abnormalities and chromosomal aberration.

Type

- *Typical type*—trisomy-21 with 47 chromosomes (95 percent of cases).
- *Translocation type*—46 chromosomes.
- *Chromosomal mosaicism*.

Clinical Features

- *Skull*—flat face, large anterior fontanelle, open sutures. There is also brachycephalic skull shaped with frontal prominence and occipital flattening (**Figs 34-33A and B**).
- *Palpebral fissures*—they are almond shaped with superior-lateral or Mongolian obliquity.
- *Eyes*—small slanting eyes with epicanthal folds. Eyes are widely spaced. There is also ocular hypertelorism.
- *Nose*—there is flattened nasal bridge (**Fig. 34-33**).
- *Others*—sexual underdevelopment, cardiac abnormalities and hypermobility of the joints.

Figs 34-33A and B: Brachycephalic skull shaped with widely shaped eyes. Nose has flattened bridge.

Oral Manifestations

- **Tongue**—macroglossia with protrusion of tongue (**Fig. 34-34**), fissured tongue or pebbly tongue from enlargement of papilla.
- **Others**—open mouth, frequent prognathism and high arched palate.
- **Maxillary sinus**—there is hypoplasia or aplasia of maxillary sinus.
- **Teeth**—teeth are malformed, enamel hypoplasia and microdontia.
- **Malocclusion**—it attributable to small maxillary arch relative to the mandibular arch.
- **Periodontal disease**—universal severe destructive periodontal disease that do not appear to be local in origin.

Fig. 34-34: Malocclusion with macroglossia of tongue (Courtesy Dr Parate).

Radiological Features

- **Periodontal destruction**—periodontal destruction of bone can be observed on the radiograph (**Fig. 34-35**).

Fig. 34-35: Periodontal destruction of bone seen in the OPG (Courtesy Dr Parate).

Diagnosis

- **Clinical diagnosis**—wide open eyes with brachycephalic shaped with malocclusion will give clue to the diagnosis.
- **Radiological diagnosis**—it is not specific.

Management

There is no specific treatment for this syndrome and many patient died during first year of life.

Achondroplasia

It is also called as '*chondrodystrophia fetalis*'. It is a disturbance of endochondral bone formation, which results in a characteristic form of dwarfism. It is a hereditary condition, which is transmitted as an autosomal dominant trait.

Clinical Features

- **Appearance**—patient is quite short, usually less than 14 meters in height and thickened muscular extremities, brachycephalic skull and bowed legs.
- **Hands**—hands are usually small and fingers are stubby.
- **Skull**—the base of the skull is small and constricted as a result of retarded growth of the cartilaginous portions. The calvarium is large and bulges frontally and laterally.
- **Nose**—there is also depression of the bridge of nose.
- **Lumbar lordosis**—lumbar lordosis with prominent buttocks and protruding abdomen is often present.
- **Joints**—joints exhibit limitation of motion.
- **Others**—arms do not hang freely at the sides and the elbows can not be straightened.

Oral Manifestations

- **Prognathism**—maxilla is often retruded because of restriction of growth at the base of skull which may produce relative mandibular prognathism.
- **Teeth**—congenital missing teeth with disturbances in shape of teeth may also occur.

Radiographic Features

- **Shorter bone and bone clubbing**—long bones are shorter than normal and there is thickening or mild clubbing at the ends.
- **Epiphysis**—epiphysis may close, either early or late.
- **Narrow foramen magnum**—bones at the base of the skull fuse prematurely, producing shortening as well as a narrow foramen magnum.

Diagnosis

- **Clinical diagnosis**—short bone, depression of nose, malocclusion of teeth and prognathism will give clue to diagnosis.

- *Radiological diagnosis*—narrow foramina magnum and short bone
- *Laboratory diagnosis*—there is retardation or even aplasia of zone of provisional calcification of endochondral growth. Cartilage columns lack orderly arrangement, fail to calcify properly and are not resorbed and replaced by bone in the usual fashion.

Management

There is no specific treatment for this disease.

Skeletal Fluorosis (Fluoride Toxicity)

Fluoride toxicity can be manifested in two forms i.e. acute and chronic. It can be caused by mutation and other genetic disorders.

Clinical Features

- *Symptoms*—nausea, vomiting and epigastric distress. Excess salivation, diarrhea and mucus discharge with headache and sweating. There is pain in joints of hand, feet and spine.
- *Signs*—barely detectable pulse, hypotension, cardiac arrhythmias and disturbance in electrolyte balance. There is also stiffness of gait, limitation of movement occurs.
- *Severe cases*—in most severe cases, there is almost crippling of movement and extreme pain because the spine and joints become rigid and virtually, immobilization of the individual occurs.
- *Complication*—respiratory and metabolic acidosis and coma.

Radiographic Features

- *Bone density*—density of bone is increased.
- *Thickening of bone*—bones of extremities show thickening and osteophytes.
- *Calcification*—calcification occurs in tendons and ligaments.

Diagnosis

- *Clinical diagnosis*—excess salivation, headache, sweating and joint pain will give clue to diagnosis.
- *Radiological diagnosis*—calcification and thickening of bone.

Management

- *Elimination of fluoride from body*—all attempts should be to eliminate the toxic dose of fluoride from the body.
- *Maintenance of vital signs*—support all the vital signs.

- *Emetics*—administer emetics if the patient possesses a gag reflex i.e. if he is not vomiting.
- *Glucose*—glucose, to reverse hyperkalemia and calcium gluconate to maintain sodium and calcium levels must be given.
- *Sodium bicarbonate*—sodium bicarbonate or Ringer lactate must also be given to increase salivary flow, decrease acidosis, to increase pH and to increase excretion of fluoride.

Generalized Cortical Hyperostosis

It is also called as 'Von Buchem disease' and it represents an excessive deposition of endosteal bone throughout the skeleton in a pattern suggestive of a hereditary condition, with an autosomal recessive characteristic.

Clinical Features

- *Appearance*—facial appearance of this patient may be swollen, particularly with widening of the angles of mandible and at the bridge of nose.
- *Symptoms*—in some patients, there is loss of visual activity and loss of facial sensation; some degree of facial paralysis and deafness occurs and all this is due to cranial nerve involvement through closure of foramina.
- *Alveolar process*—intraorally, there is sometimes overgrowth of alveolar process.

Radiological Features

- *Increase density*—a skeletal radiograph reveals increased density of many bones of body.
- *Skull sclerosis*—the skull exhibits diffuse sclerosis which may be present in the jaws.

Diagnosis

- *Clinical diagnosis*—overgrowth of alveolar process, facial paralysis and deafness.
- *Radiological diagnosis*—skull sclerosis, and increases density of bone
- *Laboratory diagnosis*—the bone is normal dense bone, but without evidence of remodeling.

Management

There is no treatment although patient may live his normal life.

Massive Osteolysis

It is also called as 'vanishing bone', 'disappearing bone', 'phantom bone', 'progressive osteolysis' or 'Gorham syndrome'. It is characterized by spontaneous, progressive resorption of bone with ultimate total disappearance of bone.

Pathogenesis

In this condition, there is progressive destruction of bone. The bone is replaced by fibro-vascular tissue. It occurs due to proliferative vascular and connective tissue response to unknown mechanism.

Clinical Features

- *Age and sex distribution*—it is most common in older children, young and middle age adults. There is no sex predilection.
- *Sites*—the most commonly affected bones are the clavicle, scapula, humerus, ribs, ilium, ischium and sacrum.
- *Symptoms and progress*—the disease may or may not be painful, begins suddenly and advance rapidly, until the involved bone is replaced by a thin layer of fibrous tissue surrounding a cavity.

Oral Manifestations

- *Site*—intraorally mandible is more commonly affected as compared to maxilla.
- *Symptoms*—the patients may present with pain or facial asymmetry. In some cases there is history of gradual progressive recession of the lower jaw.
- *Pathological fracture*—there is pathologic fracture of bone following even minor trauma.
- *Signs*—there may be complete destruction of mandible (**Fig. 34-36**). Deviation of mandible can also occur in the affected side. Ulceration of the lesion is usually absent.

Fig. 34-36: Destruction of mandible seen with no ulceration in buccal mucosa in mandibular posterior region (Courtesy Dr Chandrasekhar Kadam).

Radiological Features

- *Radiodensity*—it has got osteolytic pattern radiologically.
- *Appearance*—radiolucency is present in the mandible showing complete destruction. Margins of the lesion are indistinct (**Fig. 34-37**).

Fig. 34-37: Vanishing bone disease showing destruction of bone on left side of the mandible (Courtesy Dr Chandrasekhar Kadam).

- *Lamina dura*—there is absence of lamina dura and thinning of cortical plates.

Diagnosis

- *Clinical diagnosis*—pain, facial asymmetry and pathological fracture without any apparent cause may suspect massive osteolysis
- *Radiological diagnosis*—it will show complete destruction of bone in the jaws
- *Laboratory diagnosis*—biopsy shows vascular proliferation with osteoclastic reaction.

Management

- *Surgical*—it can be managed by intra-periosteal or extraperiosteal resection followed by autogenous grafts.
- *Radiation therapy*—some authors suggest that the role of moderate dose of radiation therapy. It is one of most successful treatment for the massive osteolysis.
- *Zeledronic acid*—it has got anti-angiogenic properties which inhibits osteoclasts can be useful in resorptive process of vanishing bone disease.
- *Nutritional treatment*—vitamin D-50000 units/week, calcium glycerophosphate 6 gm/day and fluoride.
- *Other treatment*—various other treatment modalities like chemotherapy, calcitonin, mithramycin disphosphonates also has been tried but with limited success.

Introduction

AIDS is a devastating fatal disease which is in epidemic form throughout the world. It is an incurable viral STD (sexually transmitted disease) which is caused by human immunodeficiency virus (HIV). It stands for:-

- *A*—Acquired, i.e. contagious not inherited.
- *I*—Immune, i.e. power to resist disease.
- *D*—Deficiency.
- *S*—Syndrome, i.e. number of signs and complaints indicative of a particular disease.

The case of AIDS was detected in *June 1981* when five young homosexual men came with the suffering from rare lung infection due to microorganism called *Pneumocystis carinii*. In India, the first description of AIDS came in Chennai where six women out of 125 who were screened were HIV positive in high risk group of prostitutes.

HIV attacks the immune system of the body. Due to that an individual is not able to protect himself from potentially harmful organism.

AIDS appears to be endemic in central and equatorial Africa and it may be old disease of Africa that has gone unrecognized. HIV infection has also become the primary emphasis of effort at controlling STDs. Moreover, the knowledge gain about sexual and other behavior associated with transmission of HIV, as well as strategies that have been effective in modifying those behaviors, is transferable to other sexually transmittable and blood-borne infections. These above factors have revolutionized standard approaches to the control of these infections.

Oral and perioral lesions are common in patients with human immunodeficiency virus, which are often the presenting feature and may have deterioration of general health and a poor prognosis.

Definition

WHO has given the following definition of AIDS.

- One or more opportunistic infections listed in clinical features that are at least moderately indicative of underlying cellular immune deficiency.
- Absence of all known underlying causes of cellular immune deficiency (other than HIV infection) and absence of all other causes of reduced resistance reported to be associated with at least one of those opportunistic diseases.

Prevalence

It is more common in African country and Western countries particularly in the United States. The largest population of AIDS occurs in homosexuals, intravenous drug users, and heterosexuals with sexual contact with AIDS patient. It can also occur in patients who received transfusion of blood or blood pigments donated by the person with risk factors. About 92% of victims are males, 6.5% females with 1% children. It is common in the age group of 25 to 49 years.

Transmission

- *Sexual transmission*—it is in 90% of cases. It depends upon number of sexual partners, receptive anal intercourse and presence of other STDs. All these are in high risk group. Prostitution is a major heterosexual factor associated with AIDS. Homosexuals have more risk of transmitting HIV than the heterosexual males.
- *Use of contaminated blood products*—intravenous drug users, HIV-contaminated blood transfusion, blood clotting concentrate and organ transplantation.
- *Perinatal transmission*—it occurs in 13% among children born to HIV seropositive mother.
- *Other nosocomal routes*—transmission from patient to patient due to reuse of contaminated and shared needles.

- *Professional hazards*—the risk of transmission from HIV-infected patient to health care workers is more than health care workers to patient.
- *Saliva transmission*—HIV has been found to be present in saliva. Saliva reduces the ability of HIV to infect its target cells. So transmission through saliva is rare possibility. But, there are some rare example which documented that HIV is transferred from the saliva of the patient.

History of Nomenclature of Virus

- *T lymphocytes*—there is quantitative and qualitative deficiency of T₄ helper cells in AIDS patients. This lead to certain investigators to focus their efforts on determining if etiologic agent was a virus that manifested a particular tropism for T₄ helper lymphocytes.
- *HTLV-III virus*—Dr Robert C Gallo determined that type C retrovirus was tropic for T₄ lymphocytes in adult T-cell leukemia/lymphoma. He named the virus, *Human T cell leukemia/lymphoma virus (HTLV-I)*. So, it is considered to be etiological agent for AIDS. It causes lymphoproliferation in T cell leukemia, whereas AIDS is a disease of lymphodepletion. The answer came in the discovery of type D retrovirus of HTLV family that has been termed as HTLV-III.
- *LAV virus*—on the other hand, virus called lymphadenopathy associated virus (LAV) was isolated from the AIDS patient in Europe.
- *Cytopathic human T lymphocytotropic virus*—HTLV III and LAV are closely related members of same class of virus. Finally it is proved that HTLV and LAV are cytopathic human T-lymphocytotropic viruses that manifested selective infectivity for the helper/inducer subset of T cells that as phenotypically designated reactivity with monoclonal antibody T₄ or Leu₃.
- *HIV*—in order to avoid different nomenclatures, retrovirus responsible for the AIDS are named 'Human immunodeficiency virus' which belong to family of retroviruses.

Characteristic of the HIV Virus

HIV virus is lymphotropic virus and its primary target is T₄ cell. HIV is a spherically enveloped virus, about 90-120 nm in size which is much smaller than bacteria. The nucleocapsid has an outer icosahedral shell and inner cone-shaped core, enclosing the ribonucleoproteins.

The genome is diploid, composed of two identical single stranded, positive sense RNA copies. Inside the envelops, there is a protein core, which contains enzymes reverse

transcriptase, integrase, protease etc. all essential for viral replication and maturation.

When the virus infects a cell, the viral RNA is transcribed by the enzymes, first into single-stranded DNA and then to double-stranded DNA (provirus) which is integrated into the host cell chromosomes. The virus is extremely sensitive to heat, thus boiling and autoclaving are very effective measures of inactivating the virus.

Mechanism of Action

- *Normal mechanism*—pathogenic viruses → identified by macrophage → it activates T lymphocytes → it gets differentiated into effector cell like T helper cell (T₄) and T suppresser cell (T₈) → T₄ cells secrete various lymphokines which induce lymphocyte to be differentiated into plasma cell → it secretes specific antibodies against viral antigen → it destroys the virus.
- *Mechanism in AIDS*
 - *Antigenic stimulation*—when the virus enters the blood stream, it evokes antigenic stimulation which activates CD4, T helper lymphocytes and macrophages.
 - *Secretion of TNF and interleukin 6*—lymphocytes and macrophages then secrete growth factors, tumor necrosis factor (TNF) and interleukin-6. This results in increase in CD4 cells thereby increasing number of cells vulnerable for HIV virus.
 - *Adherence of virus to CD4 cells*—HIV virus then adheres to CD4 surface via interaction between viral gp120 surface glycoprotein and CD4 cell surface membrane receptors. This surface interaction occurs with the help of transmembrane protein (chemokine receptor-5 or CCR-5).
 - *Replication of HIV virus*—after this, HIV virus will replicate in CD4 cell which also proliferates by antigenic stimulus.
 - *Incubation period*—once the viral genes are integrated into cells of own DNA, they can apparently remain dormant for an indefinite period of time, without causing any effects. This is called as 'incubation period'.
 - *Fate of CD4*—initially CD4 cells reduce the number of HIV virus by cellular and humoral attacks. But as continuous replication of virus occurs in lymph nodes, it will destroy the lymph nodes. This will lead into unchecked replication of virus which will lead to decrease in CD4 count of the human being. When the number of CD4 count is severely depleted below 200/mm³, the immune system collapses and variety of infections occur. At this stage, the patient is said to have AIDS.
- *Window period*—it is time between entry of virus into the body and the blood test becoming positive. This period

is about 1 to 3 month and person is infectious during that period.

Six Groups at Risk of Developing AIDS

- Homosexuals or bisexuals—71.4%
- Intravenous drug users—18.4%
- Hemophilia
- Recipient of multiple blood transfusion
- Infant born of parents belonging to first 3 high risk groups
- Heterosexual contacts of high risk group.

Classification

1993 Revised Classification System for HIV Infection

The Centers for Disease Control and Prevention (CDC) has revised the classification system for HIV infection to emphasize the clinical importance of the CD4+, T-lymphocyte count in the categorization of HIV-related clinical conditions. Consistent with the 1993 revised classification system, CDC has also expanded the *AIDS surveillance case definition* to include all HIV-infected persons who have less than 200 CD4+, T-lymphocytes/ μ L, or a CD4+, T-lymphocyte percentage of total lymphocytes of less than 14. This expansion includes the addition of three clinical conditions *pulmonary tuberculosis, recurrent pneumonia, and invasive cervical cancer*.

Measures of CD4+, T-lymphocytes are used to guide clinical and therapeutic management of HIV-infected persons. The revised CDC classification system for HIV-infected adolescents and adults categorizes persons on the basis of clinical conditions associated with HIV infection and CD4+, T-lymphocyte counts. The system is based on three ranges of CD4+, T-lymphocyte counts and three clinical categories.

CD ₄ + T cell categories	A Asymptomatic, acute HIV and PGL	B Symptomatic, not A or C conditions	C AIDS indicator condition
Category 1 > 500/ μ L (>28%)	A ₁	B ₁	C ₁
Category 2 : 200 to 499/ μ L (14-28%)	A ₂	B ₂	C ₂
Category 3 < 200/ μ L (<14%)	A ₃	B ₃	C ₃

Category A

It consists of one or more of the conditions listed below in an adolescent or adult (greater than or equal to 13 years)

with documented HIV infection. Conditions listed in Categories B and C must not have occurred.

- *Asymptomatic HIV infection*
- *Persistent generalized lymphadenopathy*
- *Acute (primary) HIV infection with accompanying illness or history of acute HIV infection*

Category B

It consists of symptomatic conditions in an HIV-infected adolescent or adult that are not included among conditions listed in clinical Category C and that meet at least one of the following criteria:

- The conditions are attributed to HIV infection or are indicative of a defect in cell-mediated immunity.
- The conditions are considered by physicians to have a clinical course or to require management that is complicated by HIV infection.

Examples of conditions in clinical category B include, but are not limited to:

- *Bacillary angiomatosis*
- *Candidiasis, oropharyngeal (thrush)*
- *Candidiasis, vulvovaginal; persistent, frequent, or poorly responsive to therapy*
- *Cervical dysplasia (moderate or severe)/cervical carcinoma in situ*
- *Constitutional symptoms, such as fever (38.5°C) or diarrhea lasting greater than 1 month*
- *Oral hairy leukoplakia*
- *Herpes zoster (shingles), involving at least two distinct episodes or more than one dermatome*
- *Idiopathic thrombocytopenic purpura*
- *Listeriosis*
- *Pelvic inflammatory disease, particularly if complicated by tubo-ovarian abscess*
- *Peripheral neuropathy*

For classification purposes, Category B conditions take precedence over those in Category A. For example, someone previously treated for oral or persistent vaginal candidiasis (and who has not developed a Category C disease) but who is now asymptomatic should be classified in clinical Category B.

Category C

Conditions included in the 1993 AIDS surveillance case definition

- *Candidiasis of bronchi, trachea, or lungs*
- *Candidiasis, esophageal*
- *Cervical cancer, invasive **
- *Coccidioidomycosis, disseminated or extrapulmonary*
- *Cryptococcosis, extrapulmonary*
- *Cryptosporidiosis, chronic intestinal (greater than 1 month's duration)*

- Cytomegalovirus disease (other than liver, spleen, or nodes)
- Cytomegalovirus retinitis (with loss of vision)
- Encephalopathy, HIV-related
- Herpes simplex: chronic ulcer(s) (greater than 1 month's duration); or bronchitis, pneumonitis, or esophagitis
- Histoplasmosis, disseminated or extrapulmonary
- Isopsoriasis, chronic intestinal (greater than 1 month's duration)
- Kaposi's sarcoma
- Lymphoma, Burkitt's (or equivalent term)
- Lymphoma, immunoblastic (or equivalent term)
- Lymphoma, primary, of brain
- Mycobacterium avium complex or *M. kansasii*, disseminated or extrapulmonary
- Mycobacterium tuberculosis, any site (pulmonary * or extrapulmonary)
- Mycobacterium, other species or unidentified species, disseminated or extrapulmonary
- Pneumocystis carinii pneumonia
- Pneumonia, recurrent *
- Progressive multifocal leuko-encephalopathy
- Salmonella septicemia, recurrent
- Toxoplasmosis of brain
- Wasting syndrome due to HIV

*Added in the 1993 expansion of the AIDS surveillance case definition. (This classification is in adapted form of CDC).

Walter Reed Staging System

The Walter Reed staging system of HIV infection classifies patients on the basis of CD4 counts, skin-test responsiveness, lymphadenopathy, oral candidiasis and opportunistic infections. It has limitations with respect to predictive value.

WHO Clinical Staging of HIV/AIDS and Case Definition

The clinical staging and case definition of HIV for resource-constrained settings were developed by the WHO in 1990 and revised in 2007. Staging is based on clinical findings that guide the diagnosis, evaluation, and management of HIV/AIDS, and does not require a CD4 cell count.

Primary HIV Infection

- Asymptomatic
- Acute retroviral syndrome

Clinical Stage 1

- Asymptomatic.
- Persistent generalized lymphadenopathy.

Clinical Stage 2

- Moderate unexplained weight loss (<10% of presumed or measured body weight).
- Recurrent respiratory infections (respiratory tract infections, upper respiratory infections, sinusitis, tonsillitis, bronchitis, otitis media, pharyngitis).
- Herpes zoster.
- Minor mucocutaneous manifestations (angular cheilitis, recurrent oral ulcerations, seborrheic dermatitis, prurigo, papular pruritic eruptions, fungal fingernail infections).

Clinical Stage 3

- Unexplained severe weight loss (>10% of presumed or measured body weight).
- Unexplained chronic diarrhea for >1 month.
- Unexplained persistent fever for >1 month (> 37.6°C intermittent or constant).
- Persistent oral candidiasis (thrush).
- Oral hairy leukoplakia.
- Pulmonary tuberculosis within the last 2 years.
- Severe presumed bacterial infections (e.g. pneumonia, empyema, pyomyositis, bone or joint infection, meningitis, bacteremia).
- Acute necrotizing ulcerative stomatitis, gingivitis or periodontitis.
- Conditions for which confirmatory diagnostic testing is necessary.
- Unexplained anemia (hemoglobin <8 g/dL).
- Neutropenia (neutrophils <500 cells/ μ L).
- Chronic thrombocytopenia (platelets <50,000 cells/ μ L).

Clinical Stage 4

- HIV wasting syndrome, as defined by the CDC.
- *Pneumocystis jiroveci* (formerly *carinii*) pneumonia.
- Recurrent severe or radiological bacterial pneumonia.
- Chronic herpes simplex infection (oral or genital, or anorectal site) for >1 month.
- Esophageal candidiasis.
- Extrapulmonary tuberculosis.
- Kaposi's sarcoma.
- Central nervous system toxoplasmosis.
- HIV encephalopathy.

Conditions for which a confirmatory diagnostic testing is necessary:

- Cryptococcosis, extrapulmonary
- Disseminated non-tuberculosis *Mycobacterium* infection.
- Progressive multifocal leukoencephalopathy
- Candidiasis of the trachea, bronchi, or lungs
- Chronic cryptosporidiosis
- Chronic isosporiasis

- Visceral herpes simplex infection, cytomegalovirus infection (retinitis or organ other than liver, spleen, or lymph node)
- Any disseminated mycosis (e.g. histoplasmosis, coccidioidomycosis, penicilliosis)
- Recurrent nontyphoidal *Salmonella* bacteremia
- Lymphoma (cerebral or B-cell non-Hodgkin's)
- Invasive cervical carcinoma
- Visceral leishmaniasis

USPHS–CDC Classification

This classification is given by United State Public Health Service Center of Disease Control

- *Group I*—acute infection
- *Group II*—asymptomatic infection
- *Group III*—persistence generalized lymphadenopathy.
- *Group IV*—other disease
 - *Subgroup A*—constitutional diseases
 - *Subgroup B*—neurological diseases
 - *Subgroup C*—secondary infectious diseases
- *C₁*—specified secondary infectious diseases listed in CDC surveillance definition for AIDS.
- *C₂*—other specified secondary infectious stages:
 - *Subgroup D*—secondary cancer
 - *Subgroup E*—Other conditions

AIDS-related Complex

In some persons before the development of obvious AIDS, some clinical and laboratory findings are present. This is called AIDS-related complex. For clinical and research studies, persons exhibiting complex clinical problems and immunological or hematological abnormalities on the laboratory tests, have been classified as having AIDS-related complex (ARC). **ARC** requires any two or more symptoms and two or more abnormal laboratory findings. It must be present for at least 3 months.

- *Clinical finding*—it includes lymphadenopathy, weight loss of 15 lbs or 10% of body weight, fever of 38.5°C which is intermittent or continuous, diarrhea, fatigue, malaise, night sweats and oral candidiasis.
- *Laboratory finding*—there is decreased number of T helper cell, decreased ratio of T helper cells to T suppressor cells. There is also anemia, leucopenia, thrombocytopenia, lymphopenia, increased serum globulin level, decreased blastogenic response of lymphocytes to mitogen and increased level of circulating immune complex.
- *Cutaneous anergy*—cutaneous anergy to multiple skin test antigens. Anergy is impaired or inability to react to skin antigens.

Clinical Features

- *Acute symptoms*—they are more or less like infectious mononucleosis. Patient complaint of sore throat, fever, headache, myalgia, arthralgia, diarrhea, photophobia, maculopapular rash and peripheral neuropathy.
- *Protozoa and helminthes infection*—the most common opportunistic infection is by *Pneumocystis carinii* which causes pneumonia, CNS infection or other disseminated infections and toxoplasmosis, cryptosporidiosis (intestinal) causing diarrhea for over one month
- *Fungal infection*—*Candida* organism may cause esophageal candidiasis, bronchial or pulmonary candidiasis. Cryptococcosis causing CNS infection. Patients may suffer from disseminated histoplasmosis.
- *Bacterial infections*—*Mycobacterium avium* intracellulare causing infection disseminated beyond lung and lymph node. *Mycobacterium tuberculosis* causing tuberculosis.
- *Viral infections*—cytomegalovirus, causing infection in the internal organs other than liver, spleen and lymph nodes. Herpes simplex virus, causing chronic mucocutaneous infection with ulcers persisting more than one month.
- *AIDS dementia complex*—this is most common manifestation of AIDS. It is progressive encephalopathy.
- *Persistent generalized lymphadenopathy*—in silent phase patients may have persistent generalized lymphadenopathy. Most frequent sites involved in PGL are cervical, occipital and axillary lymph nodes.
- *Malignancy*—Kaposi's sarcoma is the most common vascular malignancy seen in AIDS patient. Kaposi's sarcoma usually occurs in homosexuals. Another malignancy which may occur is non-Hodgkin's lymphoma which most commonly affects CNS.

Oral Manifestations

Oral manifestations of HIV disease are common and include oral lesions and novel presentations of previously known opportunistic diseases. Careful history taking and detailed examination of the patient's oral cavity are important parts of the physical examination and diagnosis requires appropriate investigative techniques. Early recognition, diagnosis and treatment of HIV-associated oral lesions may reduce morbidity. The presence of these lesions may be an early diagnostic indicator of immunodeficiency and HIV infection, may change the classification of the stage of HIV infection and is a predictor of the progression of HIV disease. About 95% of AIDS patients have head and neck lesion and about 55% have important oral manifestation. They are depicted in **Table 35-1**.

Table 35-1: Oral disorders in HIV disease

Fungal*More common*

- Candidiasis

Less common

- Aspergillosis
- Histoplasmosis
- *Cryptococcus neoformans*
- Geotrichosis

Bacterial*More common*

- HIV gingivitis
- HIV periodontitis
- Necrotizing gingivitis

Less common

- *Mycobacterium avium intracellulare*
- *Klebsiella pneumoniae*
- *Enterobacterium cloacae*
- *E. coli*
- *Salmonella enteritidis*
- Sinusitis
- Exacerbation of apical periodontitis
- Submandibular cellulitis

Viral*More common*

- Herpes simplex
- Varicella zoster
- Epstein-Barr including hairy leukoplakia

Less common

- HPV virus
- CMV virus
- Pox virus

Neoplasm*More common*

- Kaposi's sarcoma

Less common

- Non-Hodgkin's lymphoma
- Squamous cell carcinoma

Lymphadenopathy**Neurologic disorders***Less common*

- Paresthesia
- Facial palsy
- Hyperesthesia
- Dysphagia

*Miscellaneous**Less common*

- Recurrent aphthous ulceration
- Progressive necrotizing ulceration
- Toxic epidermolysis
- Delayed wound healing
- Thrombocytopenia
- Xerostomia and sicca type syndrome
- HIV embryopathy
- Hyperpigmentation
- Granuloma annulare
- Exfoliative cheilitis
- Lichenoid and other drug reaction.

Common Oral Manifestations in AIDS

Candidiasis

Candidiasis is a common finding in people with HIV infection. Reports describe oral candidiasis during the acute stage of HIV infection, but it occurs most commonly with falling CD4+ T-cell count in middle and late stages of HIV infection. Several reports indicate that most persons with HIV infection carry a single strain of *Candida* during clinically apparent candidiasis and when candidiasis is inactive.

Clinical Features

- *Site*—patient with HIV usually has lesion of hard palate, tongue and soft palate.
- *Clinical pattern*—there are mainly four clinical pattern of candidiasis seen in AIDS patient. They are pseudomembranous, hyperplastic, erythematous and angular cheilitis.
- *Symptoms*—these lesions may be associated with a variety of symptoms, including a burning mouth, problems in eating spicy food and changes in taste. All three of these common forms may appear in one individual.
- *Pseudomembranous candidiasis (thrush)*—characteristic creamy white, removable plaques on the oral mucosa are caused by overgrowth of fungal hyphae mixed with desquamated epithelium and inflammatory cells. The mucosa may appear red when the plaque is removed. This type of candidiasis may involve any part of the mouth or pharynx.
- *Erythematous candidiasis*—Erythematous candidiasis appears as flat, red patches of varying size. It commonly occurs on the palate and the dorsal surface of the tongue. Erythematous candidiasis is frequently subtle in appearance and clinicians may easily overlook lesions, which may persist for several weeks if untreated.
- *Angular cheilitis*—it appears clinically as redness, ulceration and fissuring, either unilaterally or bilaterally at the corners of the mouth. It can appear alone or in conjunction with another form of candidiasis.
- *Hyperplastic candidiasis*—in this, candidal lesion has got firm appearance. It usually does not scrape on pressure. (Fig. 35-1).

Management

- *Topical clotrimazole*—it is the treatment of choice. Patient improves a lot after applying topical clotrimazole application.
- *Topical itraconazole*—itraconazole in as a oral rinse is also effective in controlling oral candidiasis in HIV patient.

Fig. 35-1: Hyperplastic candidiasis seen in patient with AIDS (Courtesy Dr Chole).

- **Systemic azoles**—it is given when patient is not receiving effective retroviral therapy and CD4+ count below 50% most commonly azoles which are used are fluconazole, ketoconazole, and itraconazole. All these drugs should be given carefully as they are associated with a lot of drug interaction.

Atypical Periodontal Disease

Periodontal disease is a fairly common problem in both asymptomatic and symptomatic HIV-infected patients.

Types

- **Linear gingival erythema**—also called *HIV-related gingivitis*. There is distinctive linear band of erythema (Fig. 35-2).
- **Necrotizing ulcerative gingivitis**—ulceration and necrosis of interdental papillae occurs.

Fig. 35-2: Linear gingival erythema (Courtesy Dr Soni).

- **Necrotizing ulcerative periodontitis**—also called *HIV-associated periodontitis* in which rapid loss of periodontal attachment is seen.

Clinical Features

- **Linear gingival erythema**—it often occurs in clean mouths where there is very little plaque or calculus to account for the gingivitis. In linear gingival erythema, the gingiva may be reddened and edematous. In some cases, alveolar gingiva and mucosa may demonstrate punctate diffuse erythema.
- **Necrotizing ulcerative gingivitis**—Patients sometimes complain of spontaneous bleeding. In acute-onset ulcerative gingivitis, ulcers occur at the tip of the interdental papilla and along the gingival margins (Fig. 35-3). It often elicits severe pain. The ulcers heal, leaving the gingival papillae with a characteristic *cratered* appearance.

Fig. 35-3: Ulcerative gingivitis showing ulceration at the margin of gingiva.

- **Necrotizing ulcerative periodontitis**—necrotizing ulcerative periodontitis may present as rapid loss of supporting bone and soft tissue (Fig. 35-4). Typically, these bone/tissue loss occur simultaneously with no formation of gingival pockets, sometimes involving only isolated areas of the mouth. Teeth may loosen and eventually fall out, but uninvolved sites can appear healthy.
- **Necrotizing stomatitis**—it may develop and areas of necrotic bone may appear along the gingival margin. The bone may eventually sequestrate. This resembles noma.
- **Difference between HIV-related periodontitis and non-HIV-related periodontitis**—the patient's history and clinical appearance make the diagnosis. It is sometimes difficult to distinguish this type of periodontal disease from non-HIV-related periodontal disease. However, the comp-

laints of severe pain, rapid onset and rapid destruction in an often extremely clean mouth are unusual for non-HIV-related periodontal disease.

Fig. 35-4: HIV-associated periodontitis showing extensive loss of periodontal support.

Management

- **Debridement**—removal of necrotic tissue should be carried out. After necrotic tissue is removed, irrigation with povidone-iodine solution is done.
- **Maintenance**—patient should be done periodic scaling and root planning. Oral hygiene should be maintained with a chlorhexidine mouth rinse once or twice daily.
- **Antimicrobial therapy**—in cases of NUP, metronidazole (250-mg four times daily), amoxicillin/clavulanate (Augmentin 250-mg three times daily), or Clindamycin (300-mg three times daily) should be given.

Herpes Simplex Infection

- **Forms**—it mainly appears as herpes labialis and recurrent intraoral herpes.
- **Herpes labialis**—herpes labialis occurs as characteristic lip lesion consisting of vesicles on an erythematous base that heals within 7 to 10 days.
- **Recurrent intraoral herpes**—these lesions are more widespread as compared to lesion in the non-HIV patients.
- **Treatment**—antiviral drugs and symptomatic treatment should be given. Systemic Acyclovir 30 mg/kg/day should be given. In acyclovir resistance patient, Foscarnet should be given.

Herpes Zoster

- **Occurrence**—it occurs more frequently in HIV-infected patients and carries poor prognosis.

- **Appearance**—the occurrence of unilateral vesicles that break and scab is characteristic of this infection (Fig. 35-5). This lesion persists for longer period of time than the normal course.
- **Oral features**—these conditions when present intraorally will lead to bone sequestration and loss of teeth. Pain is very severe nature.
- **Management**—acyclovir 15-30 mg/kg/day intravenously should be given for 8 hourly for 10 to 15 days.

Fig. 35-5: Intact vesicle seen in case of herpes zoster (Courtesy Dr Chole).

Hairy Leukoplakia

Oral hairy leukoplakia, which presents as a non-movable, corrugated or “hairy” white lesion on the lateral margins of the tongue occurs in all risk groups for HIV infections, although less commonly in children than in adults. It occurs in about 20% of persons with asymptomatic HIV infection and becomes more common as the CD4+ T-cell count falls below 200/mm³. Hairy leukoplakia is almost always a manifestation of HIV infection and clinicians should arrange evaluation of HIV disease.

Etiology

- **Epstein-Barr virus**—exact etiology is not known but Epstein-Barr virus (EBV) has been identified in these lesions. One hypothesis is that basal epithelial cells of lateral margin of tongue normally harbors EBV in majority of adult population, who are EBV seropositive and carrier of that disease. It is found primarily in homosexual males. Direct infection of Langerhan’s cell due to HIV-induced loss of factor essential for their integrity and function, permit reactivation of EBL with frequent epithelial hyperplasia.

Clinical Features

- **Site**—unique and significant lesion which primarily occurs unilaterally or bilaterally on the lateral border of tongue. It can also occur on dorsum of the tongue, buccal mucosa, floor of mouth, retromolar area and soft palate.
- **Appearance**—there is characteristic corrugated and white appearance. It does not rub off and may resemble the keratotic lesion.
- **Surface**—the surface is irregular and may have prominent folds (**Fig. 35-6**) or projections, sometimes markedly resembling hairs. Occasionally, however, some areas may be smooth and flat.
- **Spread**—they may also spread downward onto the ventral surface of the tongue, where they usually appear flat.
- **Pseudohairy leukoplakia**—Sometimes, white lesion satisfies many criteria for diagnosis of hairy leukoplakia, but if EBV is not present this is called 'pseudohairy leukoplakia'.

Fig. 35-6: Hairy leukoplakia present on the lateral border of tongue giving folded and hairy appearance.

Management

- **Antiviral drugs**—hairy leukoplakia usually is asymptomatic and does not require treatment. It disappeared in patients receiving high-dose acyclovir (2.5 to 3 mg per day for 2 to 3 weeks). Another antiviral drug which can be used is descyclovir.
- **Zidovudine**—HIV therapy with zidovudine affect EBV and significant regression of hairy leukoplakia occurs.
- **Topical treatment**—topical treatment with retinoid and podophyllin resins also gives temporary remission of hairy leukoplakia.
- **Others drugs**—other drugs which can use in hairy leukoplakia are phosphonoformate, topical clotrimazole (10 mg 5 times a day), nystatin (10000 units/gm 5 times a day) and ketoconazole (200 mg BD) and azidothymidine.

Kaposi's Sarcoma

It is also called '*angioreticulo-endothelioma*'. It is neoplasm of vascular endothelial origin. It is the most common tumor associated with AIDS and occurs in 1/3rd of AIDS patients.

Pathogenesis

- **Angiogenesis protein**—higher incidence of Kaposi's sarcoma is in homosexual men with AIDS as compared to heterosexuals with AIDS. It has been suggested that there is transmissible agent prevalence in homosexual population, which stimulates certain factors such as angiogenesis protein that may be critical in the pathogenesis of neoplasm. The patient with AIDS often shows clustered lesion in the oral cavity which suggests direct inoculation of mucosa with sexually transmitted agent.
- **Cytomegalovirus infection**—some theories suggest role of cytomegalovirus in the pathogenesis of Kaposi's sarcoma, but studies on prevalence of antibodies to cytomegalovirus in patient with classic and epidemic Kaposi's sarcoma have failed to demonstrate role of cytomegalovirus.
- **HHV₈ viruses**—nowadays, human herpes virus 8 (HHV₈) is thought to be in association with Kaposi's sarcoma in AIDS patient.

Types

- **Classic type**—it is rare neoplasm and occurs in older men. Usually, it appears as blue-black macule on the lower extremities. It is slow growing and rarely involves the lymph nodes and visceral organs.
- **African Kaposi's sarcoma**
 - **Cutaneous or aggressive variety**—it is considered an endemic disease and affects children. It appears as exophytic growth located in legs and arms. This form is locally aggressive and lymph node's involvement is rare.
 - **Nodular type**—it is similar to classic type.
 - **Florid variety**—it is characterized by rapidly progressive and widely disseminated lesions with visceral involvement.
 - **Lymphadenopathic variant**—the lymphadenopathic form occurs in children of 10 years age. The visceral and massive nodal involvement is common.
- **Kaposi's sarcoma with AIDS**—it is common in homosexuals but can occur in all risk groups. Male to female ratio is 20:1. Generally affects skin, oral and visceral organs. It may be the first symptom of AIDS.
- **Iatrogenic immunosuppression-associated Kaposi's sarcoma**—it is most common in recipient organ transplant. It occurs due to loss of cellular immunity.

Clinical Features

- **Site**—it occurs commonly in head and neck region. Tip of nose is peculiar and frequent location of it. It involves lymph nodes, soft tissue, extremities, gastrointestinal tract (GIT), lung, liver, pancreas, spleen and adrenal gland.
- **Age**—it can occur at any age but most common in 5th, 6th, 7th decade except in Africa where it occurs in children. It occurs most commonly in men but also has been observed in women.
- **Appearance**—it begins as multinucleated neoplastic process that manifests as multiple red or purple macules and in more advanced stage, a nodule occurring on the skin or mucosal surface.
- **Size**—it ranges from a few millimeters to a centimeter or more in diameter and is usually tender on palpation.

Oral Manifestations

- **Site**—it has tendency to involve the oral cavity, with hard palate as the most common site. But lesions may occur on any part of the oral mucosa including the gingiva, soft palate, buccal mucosa and in the oropharynx. It can involve either alone or in association with skin and disseminated lesions.
- **Appearance**—it can appear as a red, blue, or purplish lesion. It may be flat or raised, solitary or multiple. Occasionally, yellowish mucosa surrounds the lesion. The lesions may enlarge, ulcerate and become infected.
- **Symptoms**—patient may complain of pain and interference of lesion with eating and speaking
- **Signs**—lesions are tender and painful on palpation. After some period, the area may develop in plaque and nodule. In some cases, necrosis of tissue occurs.
- **Size**—it may vary in size from few millimeters to a centimeter or more in diameter.
- **Teeth mobility**—neoplasm can invade the bone causing mobility of the tooth.

Management

- **Oral prophylaxis**—it is important to perform thorough dental prophylaxis before initiating therapy for lesions involving the gingiva. Response to therapy is improved if all local plaque and calculus are removed.
- **Systemic chemotherapy**—systemic chemotherapy like vinblastine, vincristine, etoposide, alpha interferon, adriamycin, actinomycin D, and doxorubicin should be given.
- **Intralesional sclerosing agents**—intralesional injection of sodium tetradecyl sulfate has been effective for oral lesion.
- **Intralesional vinblastine**—it is useful for treating small lesions, particularly on the palate or gingiva. Several

studies have documented the effectiveness of one or two injections of 0.1 to 0.2 mg per ml solution of Vinblastine. Post-treatment pain is fairly common, but systemic effects are rare. The pain usually disappears several days after therapy.

- **Removal of lesion**—lesion may be removed by surgical excision, cryotherapy, LASER ablation, and electrocautery.
- **Radiation therapy**—it may be indicated for large, multiple lesions. A single dose of 800 cGy or an equivalent fractionated dose is frequently used and produces a good response. Side effects include xerostomia and mucositis, although both conditions usually improve with cessation of radiation therapy.
- **Antiretroviral therapy**—drugs such as indinavir, ritonavir, and saquinavir may cause significant regression in Kaposi's sarcoma.

Uncommon Oral Manifestation in AIDS

Human Papilloma Virus Lesions

- **Clinical features**—it is caused by human papilloma virus. It can cause *Verruca vulgaris* (common wart) and oral squamous papilloma. HPV lesions in the oral cavity may appear as solitary or multiple nodules. They may be sessile or pedunculated and appear as multiple, smooth-surfaced, raised masses resembling focal epithelial hyperplasia or as multiple, small papilliferous or cauliflower-like projections. It can be found on any mucosal surface and are contagious to both host and sex partner.
- **Management**—local excision of oral wart should be carried out. Recurrence is common. Other treatment modalities which are used are topical podophyllin, interferon, cryosurgery, laser ablation and electrocoagulation.

Cytomegalovirus Infection

- **Clinical features**—it has got predilection for salivary glands because many HIV-infected patients have xerostomia. It is a hypothesis that in such patient's salivary glands, cytomegalovirus infection produces inflammation causing reduced salivary production.
- **Management**—systemic ganciclovir or Foscarnet should be given.

Aphthous Ulcer

- **Clinical features**—aphthous ulcer are reflection of immune dysfunction. Report says that pituitary suppresses the

reduced host cortisone production, might account for this lesion. It is more commonly seen on tongue (Fig. 35-7). Major and herpetiform aphthous ulcer is more commonly seen as compared to minor ulceration.

- **Management**—intralesional injection of corticosteroid give successful results. Systemic steroid should be avoided to prevent further immunosuppression. Topical corticosteroid can also be given in this patient. In case of resistance cases of aphthous ulcer, thalidomide should be given. Thalidomide should be used for short-term as it may enhance the production of HIV.

Fig. 35-7: Aphthous ulcer seen on tongue in patient with AIDS (Courtesy Dr Amit Parate).

HIV-associated Salivary Gland Disease

- **Clinical features**—salivary gland disease associated with HIV infection can present as xerostomia with or without salivary gland enlargement. It usually involves parotid gland. The enlarged salivary glands are soft but not fluctuant. Patient may complain of discomfort due to the enlarged gland. HIV-infected patients may also experience dry mouth in association with taking certain medications that can hamper salivary secretion, such as antidepressants, anti-histamines and anti-anxiety drugs.
- **Diffuse infiltrative lymphocytosis syndrome (DILS)**—in this, there is CD8 lymphocytosis, lymphadenopathy and salivary gland enlargement.
- **Management**—removal of the enlarged parotid glands is rarely recommended. For individuals with xerostomia, the use of salivary stimulants such as sugarless gum or sugarless candies may provide relief. Candies that are acidic should be avoided as frequent use may lead to loss of tooth enamel. The use of salivary substitutes may also be helpful. For DILS, oral prednisolone and anti-retroviral therapy should be given.

Idiopathic Thrombocytopenic Purpura

- **Clinical features**—reports have described idiopathic thrombocytopenic purpura in HIV-infected patients. Oral lesions may be the first manifestation of this condition. Petechiae, ecchymosis and hematoma can occur anywhere on the oral mucosa. Spontaneous bleeding from the gingiva can occur and patients may report finding blood in their mouth on waking.
- **Management**—it best responds to anti-retroviral therapy.

Molluscum Contagiosum

- **Clinical features**—it is skin disease caused by pox virus. Lesions are waxy, dome-shaped papule with central crater. Facial skin also becomes commonly involved.
- **Management**—it is managed by curettage, cryosurgery and cautery. Recurrence is common. Resolution of lesion is also seen with anti-retroviral therapy.

Lymphoma

- **Clinical features**—most of the lymphoma present are non-Hodgkin's lymphoma. CNS involvement is seen with lymphoma. Oral lesion presents as soft tissue enlargement of the palate or gingiva. There is also loss of periodontal structure resulting in mobility of tooth.
- **Management**—it is managed by chemotherapy and radiation therapy.

Squamous Cell Carcinoma

- **Clinical features**—this can occur at younger age. HIV accelerated the development of oral squamous cell carcinoma.
- **Management**—it is managed by surgical removal, radiation therapy and chemotherapy.

Guidelines to Prevent Transmission to Dentist

- **Redesigning of instrument**—call for 'redesign' of instrument of surgical procedures that carry high risk of intra-operative injury to clinical staff.
- **Sterilization**—the understanding that all instruments used in dental procedures must either be sterilized before further use or be discarded.
- **Waste management**—elimination and protection from blood contaminated aerosols. Hazardous clinical waste should be disposed properly by the waste management.
- **Management of injuries**—protocol for management of needle stick and other intra-operative injuries aiming for defining the risk in given circumstances and administration of appropriate vaccine or other preventive measures.

- *Knowing HIV antibody status of patient*—there are several circumstances in which, it is important for dentist to know HIV antibody status for ensuring accurate differential diagnosis and appropriate treatment of the oral lesions those are associated with development of AIDS. This is also needed to assess the risk to dental health care worker after needle stick or other injury from contaminated once by contact with patient's blood and saliva.

Prevention

- *Educational counseling*—education counseling of general public should be done. It will help for increasing the awareness about AIDS.
- *Sexual restriction*—one should avoid sexual contact with suspect and in high-risk group. Multiple sex partners, intimate kissing and oral contact should also be avoided.
- *Disposable syringe and needles*—one should use disposable syringes and needles.
- *Blood transfusion*—blood donor should be properly screened.
- *Safety measure*—you should also educate health-care workers on safety measures.

Diagnostic Test for AIDS

ELISA (Enzyme-linked Immunosorbent Assay)

- *Mechanism*—it is a color reaction test in which prepared whole HIV virus particle which acts as antigen, will bind with antibodies to HIV virus in an infected human serum. A serum developed from the patient's blood sample, containing antibodies, is added to the ELISA plate, which is then washed clear of inactive antibodies that will not bind to antigens. A second layer of antibodies, called a conjugate, is added to detect the primary antibodies from the human serum. Excess antibodies are again washed clear of the plate, and finally, a substrate (chromogen) is added to make reactions occur.
- *Positive test*—if *positive*, the enzyme on the antibodies, once bound to the HIV antigens, will act on the substrate, changing its color (darker color means more serum has bound to the antigen).
- *Negative test*—if *negative*, no antibodies will bind to the HIV antigens, so no enzyme will be present to change the color of the substrate (no visible change will occur).
- *Advantage*—ELISA test is simple and convenient to perform; it is very sensitive for small amount of HIV antibodies and in initial screening tests.

- *Accuracy*—it is not 100% reliable because it is not completely specific only for HIV antibodies and reacts with other related viral antibodies and other non-specific chemicals giving false-positive result of about 5 to 25 per 1000 patients. In case of positive test, there is strong indication of past exposure and infection with virus but this does not show whether the patient is infectious because it does not show whether virus is still active or has been destroyed. If ELISA is positive, more accurate western blot method should be carried out.
- *Errors*—possible errors in the ELISA test may lead to a 'false positive' or a 'false negative' result. Reasons for 'false positives' include: women who have had multiple pregnancies (who may possess antibodies directed against human leukocyte antigens, confusing the test), or the presence of other diseases such as Lyme disease, lupus, or syphilis. "False negatives" (a test failure to register the presence of HIV), may occur during the early stages of HIV infection, before seroconversion (an antibody response to the virus) has occurred.

Western Blot Method

The Western blot test is a more specific version of the ELISA, which not only indicates whether a patient is HIV-positive or negative; it allows one to see which antibodies are directed against each viral protein. It is given as a follow-up to a positive ELISA test.

- *Mechanism*—in an HIV Western blotting, viral proteins from a blood sample are passed through a gel. Different proteins migrate through the gel at different speeds; typically, smaller proteins migrate through the gel faster than larger proteins. The separated proteins are then passed through an electric current so that they can transfer on a solid film strip in order of their speed. Human serum is added, and any existing HIV antibodies will bind to the HIV antigens. A chemical that reacts on contact with a protein-antibody-enzyme layer changes band color, just as in the ELISA test. Interpreting results is complicated, but the common "3-band rule" says that if three or more bands appear, HIV antibodies have been detected.
- *Positive test*—it is indicated when the treated i.e. HIV specific nitrocellulose strips are exposed to infected human serum and a goat antihuman antibody strip displays the characteristic band detected for each of three (env, pol and gag) group of viral protein.
- *Indeterminate test*—those that react with only one of these three groups of antigens are termed indeterminate.
- *Negative*—in this, it does not react with any viral protein.
- *Advantage*—it is more specific for HIV antibodies and is used to eliminate false-positive result.

Viral Load Testing

The viral load test measures the amount of HIV virus in the body. A viral load test should not be taken as a diagnostic test. Along with the CD4 cell count, the viral load test is used to give information about the progression of HIV infection, to predict its future course, and to guide recommendations for treatment.

- **Mechanism**—there are two types of viral load tests: PCR (polymerase chain reaction), and bDNA (branched DNA). The tests use different techniques to measure the same thing, which is the amount of HIV present in bloodstream. However, it is very important to use the same type of viral load test every time and not to switch between the two, since the values on test reports from the two different types are not comparable.
- **Reports**—the test report will show the number of HIV copies in one milliliter of blood. This indicates the current level of HIV, and the rate at which it is reproducing. The higher the count and reproductive rate, the faster the disease is likely to progress.
- **High viral load**—a high viral load can be anywhere between 5,000 and one million copies or more.
- **Low viral load**—a low viral load is usually between 200 and 500 copies. However, a low viral load only indicates slow progression, not an absence of HIV or cured HIV.
- **Significance of rate of change**—the rate of change in viral load between successive tests is also important. An increasing count indicates that a worsening infection, while a decreasing count indicates suppression of the HIV infection and improvement of the patient's health.
- **Errors**—there is a chance of a “false positive” result, indicating a falsely high viral load, especially when done by the very sensitive PCR method. There is also a chance of a “false negative” when the result is undetectable; an undetectable result does not mean the patient is cured of HIV.

Alternative Diagnostic Test

- **Indirect immunofluorescence and microfiltration enzyme assay system**—it is rapid and relatively inexpensive.
- **P24 antigen capture assays**—it is used for detection of HIV DNA that may be integrated into host DNA. HIV antibody can be detected by P24 antigen capture assay within 45 days after exposure.
- **Surrogate marker**—the absolute CD₄ + T cell lymphocyte count correlate best with progression of HIV-I related immune dysfunction. Other serum neoprotein beta-2-microglobulin HIV P₂₄ antigen interleukin-2 receptor IgA and impaired delayed type of sensitivity are also used.

Management of AIDS

- **Interferon**—it has got antiviral, antiproliferative and immunomodulator activity. The interferon is a glycoprotein produced by a number of different types of cells. Type I interferon (alpha and beta) are produced by leukocytes and fibroblasts. Type II interferon (gamma) is produced by lymphocytes and monocytes. Low doses of interferon enhance the antibody formation and lymphocyte blastogenesis. They also prolong cell cycle and cause inhibition of intracellular enzyme system (anti-neoplastic effect). The gamma interferons stimulate macrophage oxidative metabolism and have antimicrobial effect.
- **Thymic replacement therapy**—thymic epithelium plays an important role in transformation of blood-borne precursor cell into mature T cells. Thymic hormone or factor mediates this effect, since the immune system in AIDS is characterized by numerical and functional defects of T cell lymphocytes, it will correct the immune defect. Transplant of fetal thymus of cultural thymic epithelium and injection of thymic hormone have been successfully utilized in treatment of AIDS.
- **Lymphokines and cytokines**—lymphokines are materials produced by lymphocyte. Interleukin-I is macrophage product. In ‘*in vitro*’ system, interleukin-I enhances plaque forming cells responses and the generation of cytotoxic T cell alloantigen. In the presence of macrophage, interleukin-1 stimulates the production of interleukin-2, which stimulates and maintains the growth of T cell activated by antigens. Various studies have conformed that purified interleukin-2 (which stimulates and maintains growth of T cell activated by antigen), preparation *in vitro* system can normalize lymphocyte reaction in high percentage of individuals with unexplained lymphadenopathy and immunologic abnormalities, but the results are not significant in patients with AIDS.
- **Bone marrow transplantation**—syngeneic (identical twin) allogeneic bone marrow transplantation has been successful in reconstituting immune function in the patients with severe congenital immune defects. If this could be therapeutic in patient with AIDS that have appropriate marrow donor.
- **Monoclonal antibodies therapy**—In this, antibodies are directed against T cell differentiation antigens as a result of that number of circulating leukemic cells are decreased in patients with adult T cell active lymphoblastic leukemia.
- **Intravenous immunoglobulin therapy**—it reduces incidence of bacterial and viral infections. Infusion of hyper-immune gamma globulin enriched for neutralizing antibodies for LAV/HTLV III could be beneficial for

individuals with AIDS or ARC who have inadequate specific antibodies.

- *HAART (highly active antiretroviral therapy)*—this therapy altered the course of epidemic. Due to this therapy, survival rate of patients is increasing. Initial therapy consists of two nucleoside reverse transcriptase inhibitor and one or two protease inhibitor. Alternatively, two nucleoside reverse transcriptase inhibitor and non-nucleoside reverse transcriptase inhibitor can be given.
- *Nucleoside reverse transcriptase inhibitor*—it includes abacavir, didanosine, lamivudine, stavudine, zalcitabine and zidovudine. These drugs inhibit viral replication by competing with natural nucleoside when HIV virus synthesizes proviral DNA using its reverse transcriptase enzyme. As a result, faulty proviral DNA does not transcribe HIV RNA and replication is blocked.
- *Non-nucleoside reverse transcriptase inhibitor*—it includes didanosine, efavirenz, and nevirapine. These drugs act as non-competitive inhibitors of reverse transcriptase enzyme.
- *Protease inhibitor*—it includes amprenavir, indinavir, nelfinavir, ritonavir and saquinavir. It acts by blocking non-infective virus that immune system can destroy.

Introduction

Hormones vary tremendously in chemical composition and in biologic activity. Various disorders of components of the endocrine system have generalized adverse effects on skeletal system due to altered metabolism.

Anatomy and Physiology

The endocrine system is specifically designed to integrate and control the human body's innumerable metabolic activities. Its functioning components are the endocrine glands. These units can function individually, in series, or in parallel, their activities being integrated closely. Communication with each other and with the tissues under their control is established by means of hormones, which they produce, store, and release as required and which are distributed throughout the body by means of the circulating blood.

In most instances, the agent stimulating or inhibiting their activity is the hormone produced by the corresponding target gland. The exceptions are the adrenal medulla, the posterior pituitary gland, and to a lesser extent, the pancreas. These glands are connected with the autonomic nervous system, secreting their hormones in response to electrical stimuli originating in higher centers in the brain and reaching them by way of the nerve fibers that link them to that system.

Pituitary Gland

- *Location*—it lies within the sella tursica at the base of brain and it is divided into three distinct lobes.
- *Lobes of pituitary gland*—the anterior lobe also called as adenohypophysis originates from epithelium of Rathke's pouch, the intermediated lobe from dorsal

portion of Rathke's pouch and posterior lobe or neurohypophysis develops from base of third ventricles.

- *Hormone secreted by anterior lobe*—hormone secreted by anterior lobe are growth hormone (GH), adrenocorticotrophic hormone (ACTH), thyroid stimulating hormone (TSH), follicle stimulating hormone (FSH), leutinizing hormone (LH) and prolactin.
- *Hormone secreted by intermediated lobe and posterior lobe*—hormone secreted by intermediated lobe is melanocytes stimulating hormone and by posterior lobe vasopressin and oxytocin.
- *Complex feedback interaction*—the secretory activities of the pituitary gland are modulated by hypothalamus through a series of complex feedback interaction.

Thyroid Gland

- *Location*—it is situated in midline of body in the neck, at the level of cricoid cartilage having two lateral lobes which are joined by isthmus. Third pyramidal lobe also extends from the isthmus.
- *Development*—embryologically the thyroid gland develops as a downgrowth from the portion of four pharyngeal pouches.
- *Function*—it regulates the basal metabolic rate, stimulates somatic and psychic growth and plays an important role in calcium metabolism.
- *Secretion from gland*—follicular cells lining the follicles of the gland secrete tri-iodothyronin and tetra-iodothyronin (thyroxin) which stimulates basal metabolic rate and somatic and psychic growth of the individuals. Para follicular cells lie in between the follicles and they secrete thyrocalcitonin which promotes deposition of calcium salts in skeletal and other tissue and tends to produce hypocalcemia.
- *Prohormone*—eighty-three percent of T_3 is produced by monodeiodination of T_4 in others tissue such as liver,

muscle and kidney. T_4 is probably not metabolically active until converted to T_3 and may be regarded as prohormone.

- **T_3 and T_4** — T_3 and T_4 circulate in plasma protein almost entirely bound to transport plasma proteins mainly thyroxin binding globulin. It is a minute fraction of unbound or free hormone, which diffuse into tissues and exerts its metabolic action. Production of T_3 and T_4 in the thyroid is stimulated by thyrotrophin (thyroid stimulating hormone—TSH), a glycoprotein released from thyrotrophic cells of the anterior pituitary in response to the hypothalamic tripeptide, thyrotrophic releasing hormone. There is negative feedback of thyroid hormones on the thyrotrophs such that in hyperthyroidism, when plasma concentration of T_3 and T_4 are raised, TSH secretion is suppressed and in hypothyroidism due to disease of the thyroid gland low T_3 and T_4 are associated with high TSH level.

Parathyroid Glands

- **Location**—the four parathyroid glands lie behind the lobes of the thyroid. They are not regulated by pituitary gland, but respond directly to changes in serum ionized calcium concentration.
- **Parathyroid hormone**—parathyroid hormone (PTH) is a single chain polypeptide of 84-amino acid which are synthesized by the chief cells and released in response to a fall in serum ionized calcium concentration.
- **Function**—PTH directly promotes reabsorption of calcium from renal tubules and bones. PTH also has indirect effect, mediated by increasing conversion of 1, 25 hydroxy cholecalciferol, which results in increase calcium absorption from the food and enhanced mobilization of calcium from bone. The initial effect of PTH on bone is to stimulate osteolysis, returning from bone to extracellular fluid.

Adrenal Gland

- **Location**—the adrenals are triangular-shaped structure that sits on the superior poles of the kidneys.
- **Secretion**—it produces and secretes a number of compounds that are essential for maintenance of life adaptation to stress.
- **Parts of gland**—each gland is divided into adrenal medulla and a cortex.
- **Adrenal medulla**—it arises from ectodermal tissues and function as a part of the sympathetic nervous system. It manufactures and secretes two catecholamine, i.e. epinephrine and norepinephrine.
 - **Epinephrine**—it supports blood pressure by increasing the heart rate. Epinephrine also increases oxygen consumption by the tissue and glucose release by the liver.

- **Norepinephrine**—norepinephrine increases peripheral resistance by its vasoconstrictor effect.
- **Metabolic effect**—epinephrine and norepinephrine also exert important metabolic effects by promoting lipolysis; increase blood sugar levels by stimulating glycogenolysis, elevating body temperature and increases basal metabolic rate. These compounds aid the body in adapting to stress which is important in the dental sitting because release of endogenous epinephrine during stressful dental procedure can produce significant changes in blood pressure and pulse rate.
- **The adrenal cortex**—it secretes three major classes of hormone: glucocorticoids or cortisols, which affects the inflammatory process and carbohydrates and protein metabolism, the mineralocorticoid, aldosterone, which affect water and electrolyte balance and sex hormone testosterone, estrogen and progesterone.

Diseases of Pituitary Gland

Hyperpituitarism

It results from hyperfunction of anterior lobe of pituitary gland, most significantly with increased production of growth hormone. The usual cause of this condition is a benign, functioning tumor of the eosinophilic cells in the anterior lobe of the pituitary gland. GH acts directly on some tissue but most of its biological effects are accounted by stimulation of secretion of insulin like growth factor I (IGF-I) and its binding proteins from the lower.

Types

- **Gigantism**—if the increase in level occurs before the epiphysis of the long bone are closed.
- **Acromegaly**—if the increase occurs later in life after epiphysis closure.

Clinical Features

Gigantism

- **Stature of individual**—generalized overgrowth of most tissue in childhood. Most of the soft tissue and bones respond to the excess hormone by enlarging. Excessive generalized skeletal growth can occur. Patient may often have of height to 7 to 8 feet. Patients achieve monstrous size because of tumors of the pituitary gland.
- **Symptoms**—later in life it may show genital underdevelopment and excessive perspiration and they complained of headache, lassitude, fatigue, muscle and joints pain and hot flashes.
- **Skull**—there is increase in size of calvarium which may lead to change in the hat size (**Fig. 36-1**). Pituitary tumors may also induce deficiency of other pituitary hormones

causing signs of hypogonadism including decreased libido and menstrual problems in women.

Acromegaly

- *Age and sex*—it is more common in males and occurs most frequently in 3rd decade.
- *Symptoms*—there is temporal headache, photophobia and reduction in vision.
- *Facial features*—bone overgrowth and thickening of the soft tissue cause a characteristic coarse (loose texture) facial appearance.
- *Hand and feet*—hand and feet become large, with clubbing of the toes and fingers due to enlargement of the tufts of the terminal phalanges. The terminal phalanges of the hands and feet become large and the ribs also increase in size.

Fig. 36-1: Increased size of skull and facial bone seen in gigantism.

Oral Manifestations

- *Symptoms*—in edentulous patients' enlargement of the alveolus may prevent the comfortable fit of complete dentures.
- *Teeth*—teeth in gigantism are proportional to the sized of jaw and the rest of the body and root may be longer than normal. The teeth become spaced, partly because of enlargement of the tongue and partly because upper teeth are situated on the inner aspect of the lower dental arch, due to disproportionate enlargement of the two jaws
- *Jaw bone*—mandibular condylar growth is very prominent. Overgrowth of mandible leading to prognathism.

Mandible may be of extraordinary proportions creating a major discrepancy between the upper and lower jaws and a pronounced class III malocclusion. In some cases the growth at the condyle exceeds that of the alveolar processes, so that increased in vertical depth of the ramus is greater than that of the body of the jaw, consequently the upper and lower teeth fail to come into proper occlusion.

- *Palate*—the palatal vault is usually flattened and the tongue increase in size and may cause crenation on its lateral border.
- *Macroglossia*—soft tissue growth may produce uniform macroglossia in patients.
- *Lips*—the lips become thick and Negroid.

Radiographic Features

- *Skull changes*—enlargement of sella tursica, enlargement of paranasal sinus (Fig. 36-2) and excessive pneumatization of temporal bone squames and petrous ridge. Diffuse thickening of outer table of skull. Enlargement and distortion of the pituitary fossa.

Fig. 36-2: Enlargement of maxillary sinus seen in hyperpituitarism patient.

- *Air sinus*—the air sinuses are really prominent in acromegaly rather than in gigantism.
- *Teeth*—increased tooth size especially root due to secondary cemental hyperplasia. Diastema between teeth due to lengthening of dental arch. Increase in thickness and height of alveolar process may results in open bite to the patient.
- *Jaw bone*—in acromegaly the angle between the ramus and body of mandible may increase, which result in anterior tooth root push forward so they appear as 'fan out'. There is also lengthening of condylar process, class III skeletal relationship. The new bone laid down on the condyle results in an increase in the vertical length of the ramus as well as overall length of whole bone. It is greater on the tip and posterior aspect of the coronoid processes, on the posterior border of the ramus and on the chin. Enlargement of the mandible, the length of the horizontal and ascending rami are both increase causing it to become prognathic with an increase obliquity of the angle and with loss of the antegonial notch.

- *Inferior dental canal*—there is also enlargement of inferior dental canal.

Diagnosis

- *Clinical diagnosis*—stature of individual gives clue to the diagnosis.
- *Radiological features*—characteristic radiographic findings may yield to the diagnosis.
- *Laboratory diagnosis*—growth hormone concentration can be measured by radioimmunoassay technique.

Management

- *Surgery*—trans-sphenoidal surgery may result in cure of GH excess especially in patients with macroadenoma.
- *Medical therapy*—octreotide, a long acting analogue of somatostatin, lowers GH. It is administered as subcutaneous insulin 2 to 3 times/day. Other somatostatin analogues like lanreotide, vapreotide can also be given in this patient. Dopamine antagonists are also used.
- *Radiotherapy*—external radiotherapy stops tumor growth and lowers GH levels. GH levels fall slowly and there is a risk of hypopituitarism.

Hypopituitarism or Pituitary Dwarfism

Pituitary is the master gland of the body. It results due to reduced secretion of pituitary hormone which may occur due to pituitary adenoma that compresses the pituitary gland. It is often the consequence of growth of pituitary gland or interference with stalk function. It results in *pituitary dwarfism*.

Pathologic changes can result from a variety of pituitary gland malfunction. Total absence of all pituitary secretions is known as *panhypopituitarism*. Hypopituitarism which commences after puberty is called as '*Simmond's disease*'.

Etiology

- *Disease of pituitary gland*—congenital or due to destructive disease of pituitary gland such as infarct occurring before puberty.
- *Space occupying lesion*—space occupying lesions involving the sella turcica like craniopharyngioma, adenomas and sarcoidosis.
- *Sheehan's syndrome*—Sheehan's syndrome is a form of hypopituitarism caused by infarction of the pituitary associated with postpartum hemorrhage.

Clinical Features

- *Short stature of individual*—the underdevelopment is symmetrical, individual is very small and in some cases there may be a disproportional shortening of the long

bones. The hallmark of this condition is that the growth is retarded to a greater degree than is bone and dental development (**Fig. 36-3**).

- *Hypocalcemia*—it may occur because of growth hormone and cortisol deficiency. Lack of gonadotrophin delays the onset of puberty.
- *Diabetic insipidus*—the presence of diabetes insipidus associated with deficient secretion of vasopressin is suggestive of pituitary dysfunction.
- *Symptoms*—growth hormone secretion is lost resulting in lethargy, muscle weakness and increase fat mass in adults.
- *Sexual characteristic*—luteinizing hormone (LH) secretion becomes impaired, in the male loss of libido and impotence and in female oligomenorrhea or amenorrhea. The male produces gynecomastia and skin becomes fair and wrinkled.
- *Skull*—the skull and facial bone are small and there is delay in maturation of the skeleton and epiphysis may remain ununited throughout the life.

Fig. 36-3: Short stature of individual in dwarfism.

Oral Manifestations

- *Jaw bone*—marked failure of development of maxilla and mandible with lack of condylar growth with short ramus and this can lead to severe malocclusion and crowding of the teeth.
- *Teeth*—the two important hormones are excreted by this gland—the somatotrophic and the thyrotrophic are responsible for the normal eruption of teeth and the

alveolar growth. Thus in case of hypofunction of this gland, the tooth eruption is hampered. The dental arch is smaller than normal and thus cannot accommodate all the teeth resulting in crowding and subsequent malocclusion. The clinical crown appears smaller than normal because even though eruption does occur it is not complete. Eruption is delayed and so the shedding of the deciduous teeth (Fig. 36-4).

Fig. 36-4: Malocclusion and delayed eruption of teeth seen in dwarfism patient

Radiographic Features

- *Teeth*—complete absence of third molar bud. Roots of teeth are short and apices are wide open and pulp canal toward the apex.
- *Alveolar bone*—there is loss of alveolar bone.

Diagnosis

- *Clinical diagnosis*—short stature of individual with respect to age will easily diagnose this condition. Eruption of teeth is also delayed.
- *Radiological diagnosis*—short root with wide open apices are present
- *Laboratory diagnosis*—radioimmunoassay will show level of growth hormone significantly below normal.

Management

- *Removal of cause*—management is usually directed towards removal of the cause.
- *Growth hormone replacement therapy*—this can be produced by recombinant DNA technology.

Progeria

It is transmitted as autosomal dominant trait. This condition is rare and underlying cause is entirely dependent on

pituitary dysfunction. It is regarded as premature senility in an individual of infantile proportions.

Clinical Features

- *Age*—affected infants appear normal at birth, but the typical clinical features become manifested within the first few years.
- *Symptoms*—patient exhibits alopecia, pigmented areas of the trunk, atrophic skin, prominent veins and loss of subcutaneous fat. The individual have high pitched squeaky voice beak like nose and hypoplastic mandible.
- *Sign*—the face is pointed, with the nose resembling the beak of a bird. The head is large, while mandible is small. Exophthalmos may be present and joint deformities. The lip is thin. The intelligence of this patient is either normal or above normal and even at early age patient behave like old person.

Oral Manifestations

- *Formation of irregular dentin*—there is accelerated formation of irregular dentin.
- *Delayed eruption*—delayed eruption of teeth can occur.

Radiographic Features

- *Long bone*—there is presence of osteoporosis of the long bones.
- *Skull bone*—there is relative overdevelopment of the frontal and parietal bones, while ossification may be delayed and deficient.
- *Jaw bone*—the mandible and maxilla are small, but the mandible shows the greatest amount of underdevelopment so that the chin is underhung.

Diagnosis

- *Clinical diagnosis*—alopecia, pigmented area on face, beak of bird nose, squeaky voice and delayed eruption of teeth may give clue to diagnosis.
- *Radiological diagnosis*—osteoporosis, delayed ossification, and underhung chin is present.

Management

No treatment and patient usually dies before the age of 27 years.

Diseases of Thyroid Gland

Hyperthyroidism

It is also called as 'thyrotoxicosis' and it is a syndrome in which there is excessive production of thyroxin in thyroid

gland. It is associated with diffuse toxic goiter and less frequently with toxic nodular goiter or toxic adenoma. Excessive thyroxine causes generalized increase in metabolic rate of all body tissues. In patient with thyrotoxicosis, dental treatment can precipitate an acute emergency like 'thyroid crisis' or 'thyroid storm'.

Etiology

- *Exophthalmic goiter*—it is characterized by diffuse hyperplasia of the thyroid and by eye signs.
- *Toxic adenoma*—in it hyperfunction originates by a benign tumor of the thyroid gland.
- *Pituitary disease*—a pituitary disease involving anterior portion of the gland.
- *Other causes*—ectopic thyroid tissue, Graves' disease, multi-nodular goiter, thyroid adenoma, choriocarcinoma, excess pituitary TSH, autonomous stroma ovarii, and polyostotic fibrous dysplasia.

Clinical Features

- *Age and sex*—it has predilection for females between 20 and 40 years of age.
- *Thyroid features*—thyroid is diffusely enlarged, smooth, possible asymmetrical and nodular, a thrill may be present, may be tender (**Fig. 36-5**).
- *Neuromuscular*—it includes nervousness, fine tremors, and muscle weakness, mood swings from depression to extreme euphoria, emotional lability, hyper-reflexia, ill sustained clonus, proximal myopathy, bulbar myopathy and periodic paralysis.
- *Gastrointestinal*—weight loss despite normal or increased appetite, diarrhea, bowel alterations, anorexia, vomiting and hyperdefecation. Abdomen, liver and spleen may be enlarged.

Fig. 36-5: Thyroid gland swelling seen in neck area due to tumor.

- *Cardiorespiratory*—palpitation, excessive perspiration, irregular heartbeat, increased metabolic activity leads to increased circulatory demands. There is also tachycardia, increased pulse pressure, and sometimes congestive cardiac failure. Exertion dyspnea, ankle edema, systolic hypertension, angina, and cardiomyopathy may be present.
- *Ocular*—in thyrotoxicosis patient may have bulging eye and partial paralysis of the ocular muscles, retraction and jerky movement, corneal ulceration, optic neuritis, ocular muscle weakness, papilledema, loss of visual activity, and exophthalmos is present.
- *Reproductive*—amenorrhea, oligomenorrhea, infertility, spontaneous abortion and loss of libido, impotence.
- *Dermatological*—increases sweating, pruritis, onycholysis, pigmentation, vitiligo, digital clubbing and pretibial myxedema (bilateral nonpitting edema).
- *Others*—heat intolerance, sweaty and warm extremities, thin shiny skin, pretibial myxedema, increased pulse rate and early fatigue, lymphadenopathy, thirst and osteoporosis.

Oral Manifestations

- *Teeth*—advanced rate of dental development and early eruption with premature loss of primary teeth.
- *Alveolar bone*—generalized decrease in bone density or loss of some areas of edentulous alveolar bone.

Radiographic Features

- *Generalized osteoporosis*—in older children and adults well marked generalized osteoporosis sometimes appears but it is not revealed in the jaw.
- *Alveolar resorption*—in some cases, there may be alveolar resorption and in some cases there may be greater density of the trabeculae.

Diagnosis

- *Clinical diagnosis*—enlargement of thyroid gland with other systemic features may give clue to diagnosis. Advanced rate of tooth development.
- *Radiological features*—generalized osteoporosis with alveolar resorption.
- *Laboratory diagnosis*—plasma levels of T_3 and T_4 are increased; free thyroxine index is raised in this disorder. Thyroid stimulating hormone (TSH) decreased. Anemia may be moderate to severe degree and is seen in patient with prolonged duration of the disease. The anemia is hypochromic and abnormal forms of RBC may be seen.

Management

- *General*—sedate the patient giving medication. Application of cold packs to lower the body temperature.

- *Antithyroid drugs*—it would be appropriated to give antithyroid drugs for 12 to 18 months to those in whom a single episode was anticipated. Carbimazole—for 0-3 weeks, 40-60 mg daily in divided doses; for 4-8 weeks, 20-40 mg daily in divided doses and for maintenance phase, 5-20 mg daily.
- *Subtotal thyroidectomy*—patients must rendered euthyroid before operation. The antithyroid drug is stopped 2 weeks before surgery and replaced by potassium iodate 170 mg daily orally.
- *Radioactive iodine*—¹³¹I acts either by destroying functional thyroid cells or by inhibiting their ability to replicate. Dose -185-370 mBq (5-10 mCi) is given orally.
- *β-adrenoreceptor antagonist*—selective β-adrenoreceptor antagonist such as propranolol (160 mg daily in divided doses or nadolol 40-80 mg once daily) will alleviate but not abolish symptoms of hyperthyroidism within 24-48 hours.

Hypothyroidism

It is caused by insufficient secretion of thyroxin by the thyroid gland. Failure of thyrotrophic function on the part of the pituitary gland or an atrophy or destruction of the thyroid gland leads to an inability of the thyroid to produce sufficient hormone to meet the requirement of the body. Hypothyroidism is caused by decreased or deficient secretion of thyroid hormones caused by thyroiditis, insufficient thyroid replacement, post-thyroidectomy, post-radioactive iodine therapy.

Types

- *Cretinism*—if failure of hormone occurs in infancy.
- *Juvenile myxedema*—if it occurs in childhood.
- *Myxedema*—if it occurs after the puberty. In it, there is subcutaneous deposition of glycosaminoglycan ground substance producing non-pitting edema.
- *Primary hypothyroidism*—thyroid gland is abnormal.
- *Secondary hypothyroidism*—in this pituitary gland does not produce adequate amount of thyroid stimulating hormone.

Clinical Features

Cretinism and juvenile myxedema

- *Age*—it may be present at birth or become evidence within the first few months after birth.
- *Symptoms*—hoarse cry, constipation, feeding problems in neonates. Retarded mental and physical growth. Patient also noticed huskiness of voice, constipation and hypothermia is present. Skin is dry to touch.
- *Bones*—delayed fusion of all body epiphysis and delayed ossification of paranasal sinus, partially pneumatization.
- *Signs*—there is protuberant abdomen with umbilical hernia. The hairs are sparse and brittle, the finger nails are brittle and the sweat glands are atrophic.

Myxedema

Symptoms

- *Early symptoms*—it includes weakness, fatigue, cold intolerance, lethargy, dryness of skin, headache, menorrhagia, and anorexia.
- *Late symptoms*—it includes slowing of intellectual and motor activity, absence of sweating, modest weight gain, constipation, peripheral edema, pallor, hoarseness, decreased sense of taste and smell, muscle cramps, aches and pains, dyspnea, anginal pain and deafness.

Signs

- *Face*—patient has dull expressionless face, periorbital edema, facial pallor, puffiness of face.
- *Eyes*—puffiness of eyelids is also present. There are also watery eyes.
- *Skin*—skin feels droughty to touch sparse hair
- *Tendon reflexes*—delayed return of deep tendon reflexes
- *Thyroid gland*—thyroid gland may be enlarged.
- *Other features*—patient may suffer from disorientation, tachycardia, diastolic hypertension, displaced apical beat, occasional purpura, thickened nose, and pleural effusion.

Complications

- Coronary artery disease, congestive heart failure.
- Increased susceptibility to infection, mental disturbances including depression.

Oral Manifestations

Cretinism and juvenile myxedema

- *Teeth*—dental development delayed and primary teeth slow to exfoliate. Enamel hypoplasia can also be seen. Abnormalities of dentin formation lead to enlarge pulp chamber.
- *Jaw bone*—maxilla is overdeveloped and mandible is underdeveloped. Retarded condylar growth leads to characteristic micrognathia and open bite relationship.
- *Tongue*—tongue is enlarged by edema fluid and due to it tongue may protruded continuously and such protrusion may lead to malocclusion of teeth.
- *Skull*—the base of skull is shortened leading to a retraction of the bridge of the nose with flaring.
- *Face*—face is wide and fails to develop in longitudinal direction.
- *Lips*—lips are puffy, thickened and protruding.

Myxedema

- *Tongue and lip*—macroglossia and enlarged lip as a result of the deposition of water and protein.
- *Face*—facial swelling of nonpitting type and mandible is underdeveloped.
- *Teeth*—there is greater tendency to periodontal disease, with alveolar destruction and loosening of the teeth.

Radiographic Features

- *Skull bones*—delayed closing of the fontanelles and epiphysis, numerous wormian bones (accessory bone in the sutures). There is transverse line of increased density involving the metaphysical regions.
- *Teeth*—reveal thinning of lamina dura. Delayed dental eruption, short tooth root. Separation of teeth as a result of enlargement of tongue, periodontal diseases and loss of teeth and external root resorption.
- *Alveolar bone*—the alveolar processes are relatively large as compared to body of bone which is smaller than in normal individuals.

Diagnosis

- *Clinical diagnosis*—sparse hair, delayed development of teeth, enamel hypoplasia and macroglossia should give clue to the diagnosis.
- *Radiological diagnosis*—thinning of lamina dura, wormian bone, and external root resorption can give clue to the diagnosis.
- *Laboratory diagnosis*—thyroid stimulating hormone (TSH) increased and T_3 and T_4 decreased. In ECG, a classical sinus bradycardia with low voltage complexes and ST/T wave abnormalities. There is raised cholesterol level and triglycerides level and low serum sodium.

Management

- *Thyroid preparation*—patients are managed by thyroid preparation. Mainly used is levothyroxin, which is available as 25, 50 and 100 mg tablets. It is customary to start slowly and a dose of 50 mg/day should be given for 3 weeks and finally to 150 mg/day. In the elders and in patient with ischemic heart disease, the initial dose should be 25 µg/day. In children it should start as early as possible to avoid major developmental and intellectual abnormalities.

Dental Consideration of Thyroid Disorders

- *Precaution*—in dentistry, the use of sedative and analgesic are dangerous as these agents tend to precipitate coma in patient with hypothyroidism.
- *Hyperparathyroidism*—inpatients with severe hyperthyroidism the emergencies likely to occur are thyroid crisis, emotional disturbances, cardiac difficulties.

- *Lowering the body temperature*—application of cold packs to lower body temperature
- *Other therapy*—other therapy like supporting respiration, narcotic antagonist, and oxygen can be given if necessary.
- *Hospitalization*—if severe, patient should be immediately hospitalized.

Diseases of Parathyroid Gland**Hyperparathyroidism**

It is an endocrine disorder in which there is an excess of circulating parathyroid hormone. Excess PTH stimulates osteoclast to mobilize calcium from skeleton leading to hypercalcemia in addition to PTH increased renal tubular re-absorption of calcium.

Following is the sequence of event which gives an idea of the reaction promoted by this hormone.

- *Target organ*—the bone and the kidney are the target organs of parathyroid hormone which mediates the osteoclast to resorb bone actively.
- *Elevation of serum calcium level*—when the bone is resorbed, calcium is released in the extracellular fluid and the serum calcium level is elevated.
- *Action of parathyroid hormone*—the parathyroid hormone acts on the epithelium of kidney tubules causing diuresis of phosphorus resulting in decrease in serum phosphorus level. At the same time it induces an increase in calcium re-absorption from glomerular filtrate. Parathyroid hormone may also increase the absorption of calcium from the intestine but this is not definitely established. Hence in a healthy person injection of parathyroid hormone produces an elevated plasma calcium level, a decreased plasma phosphorus level and an increased alkaline phosphatase level.

Types

- *Primary*—there is autonomous secretion of parathyroid hormone (PTH) by hyperplasia, benign and malignant tumor of one or more of the four parathyroid glands.
- *Secondary*—compensatory increase in output of PTH in response to hypocalcemia. The underlying hypocalcemia may result from an inadequate dietary intake or poor absorption of vitamin D or from deficient metabolism of vitamin D in the liver or kidney. Its effects to restore serum calcium level at the expense of the loss of calcium in bone.
- *Tertiary*—occasionally parathyroid tumor after long standing secondary hyperparathyroidism develops this condition known as tertiary hyperparathyroidism. The increased parathyroid level produces increased bone resorption and a resultant hypercalcemia.

- *Ectopic*—due to excessive parathyroid hormone synthesized in patient with malignant disease.

Clinical Features

- *Age and sex*—female to male ratio is 3:1. Mainly in 30 to 60 years of age.
- *Classic triad*—there is present of classic triad of kidney stones, resorption of bone and duodenal ulcers.
- *Renal calculi*—symptoms in patient occur due to renal calculi and duodenal ulcers. Patient may complain of hematuria, back pain, urinary tract infection.
- *Psychological problems*—patient may suffer from psychiatric effect like emotional instability.
- *Gastrointestinal problems*—gastrointestinal difficulties such as anorexia, nausea, vomiting and crampy pain may be present.
- *Bone*—bone pain, pathologic fractures and bone deformities occurs.
- *Hypercalcemia*—it is associated with muscle weakness, fatigue, weight loss, insomnia, headache, polydipsia and polyuria.

Oral Manifestations

- *Brown tumor*—it may develop peripherally or centrally. This can be presented as swelling which may appear intraorally or extraorally (**Figs 36-6 and 36-7**).
- *Teeth*—gradual loosening, drifting and loss of teeth, malocclusion.

Fig. 36-6: Extraoral swelling seen in patient with hyperparathyroidism due to brown tumor.

Radiographic Features

- *Demineralization of skeleton*—bone matrix contains less than normal amounts of calcium producing unusually

Fig. 36-7: Brown tumor presented as intraoral swelling in patient with drifting of teeth (Courtesy Dr Parate).

radiolucent skeletal image. There is lack of normal contrast in the radiograph resulting in over all grayness, often associated with a granular appearance in the bone.

- *Ground glass appearance*—the rarefaction is of homogeneous nature and there may be normal, granular or ground glass appearance.
- *Moth eaten appearance*—sometimes rarefaction gives a mottled or moth eaten appearance with varying density.
- *Osteitis fibrosa generalisata*—localized destruction of bone is produced by osteoclastic activity leaving residual area of fibrosis. In some cases moth eater appearance can be seen.
- *Brown tumor*—it appears radiographically as ill-defined radiolucency (**Figs 36-8 and 36-9**) called as brown tumor, as gross specimen is brown or reddish brown. In it,

Fig. 36-8: CT scan of brown tumor in patient with hyperparathyroidism.

Fig. 36-9: Brown tumor presented as radiolucency in upper maxillary region. Note also there is drifting of teeth (Courtesy Dr Parate).

trabeculae are completely missing. It may occur in pelvis, ribs or femur but are most commonly found in facial bones and jaws. They appear as unilocular or multilocular with variably defined margin and may produce cortical expansion.

- *Pathological calcification*—punctuate and nodular calcifications occasionally occur in kidneys and joints.
- *Hand bone*—earliest change is subtle erosion of bone from sub-periosteal surface of phalanges of hand.
- *Skull bones*—entire calvarium has granular appearance caused by loss of central trabeculae and thinning of cortical tables.
- *Pepper pot skull*—evidence in the skull vault of osteopenia producing a fine overall stippled pattern to the bone, hence it is called as pepper-pot skull.
- *Jaw bones*—demineralization of inferior border of mandibular canal, thinning of outlines of the maxillary sinus.
- *Teeth and alveolar bone*—if the alveolus is severely affected the teeth may become mobile and migrate. The radiopaque cortical plate outlining the bones and anatomic regions may be thinned or lost entirely. Loss of lamina dura which may be seen around one tooth or all remaining teeth. It may be complete or partial. If complete involved tooth has tapered appearance.

Diagnosis

- *Clinical diagnosis*—brown tumor, symptoms of renal calculi, peptic ulcer can diagnose this condition.
- *Radiological features*—demineralization of skeleton, pepper pot skull, brown tumor, and osteitis fibrosa cystica can give clue to the diagnosis.
- *Laboratory diagnosis*—biopsy shows osteoclastic resorption of the trabeculae of the spongiosa and along the blood vessels in the haversian system of the cortex. Fibrosis especially in the marrow spaces is marked. The serum calcium level is raised and serum phosphorus

level is decreased and serum alkaline phosphatase level is elevated in primary hyperparathyroidism and in secondary hyperparathyroidism the serum calcium level is decreased whereas the serum phosphorus and alkaline phosphatase level are elevated. Increase in circulating hormone demonstrated by radioisotope studies.

Differential Diagnosis

Unilocular

- *Postextraction socket and surgical defect*—it will give history of extraction and surgery respectively.
- *Primordial bone cyst, traumatic bone cyst and odontogenic cyst*—they all occur in a younger age group than in hyperparathyroidism and have normal serum chemistry values.

Multilocular

- *Paget disease*—calcium metabolism is normal and bone formation usually exceeds the bone resorption resulting in an elevated blood alkaline phosphatase.
- *Ameloblastoma*—it usually shows a honeycomb appearance accompanied with paresthesia and normal serum chemistry level.
- *Central giant cell granuloma*—it can only be differentiated by serum chemistry level.
- *Cherubism*—the lesion is bilateral, seen in children and also there is usually familial involvement which is not so in giant cell lesion of hyperparathyroidism.
- *Aneurysmal bone cyst and central hemangioma*—it occurs in a younger age group.
- *Osteomalacia*—blood calcium levels are decreased.
- *Fibrous dysplasia*—osseous changes are frequently localized, loss of lamina dura is less common.
- *Multiple myeloma*—lesions are punched out, generalized bone demineralization in hyperparathyroidism helps in distinguishing.

Management

- *Surgery*—hyperplastic tissue should be removed surgically.
- *Vitamin D supplement*—the oral administration of vitamin D in secondary type can prevent skeletal demineralization in most of the cases.
- *Parathyroidectomy*—it is indicated in patient where patient does not respond to treatment.
- *Precaution*—restriction of dietary phosphate, phosphate binding agent and aluminum salts should be done.

Hypoparathyroidism

It is an uncommon condition in which there is insufficient secretion of parathyroid hormone. Parathyroid hormone is needed for regulation of calcium level in extracellular tissue.

Etiology

- *Surgical damage*—surgical damage to parathyroid gland and their vascular supply during thyroid gland procedure.
- *Damage from radiotherapy*—parathyroid damage may occur from radioactive iodine 131.
- *Autoimmune*—autoimmune destruction of parathyroid gland may take place.
- *Other*—hypoparathyroidism can also be associated with DiGeorge syndrome and endocrine-candidiasis syndrome.

Clinical Features

- *Hypocalcemia*—hypocalcemia can occur due to loss of parathyroid function. It can lead to tetany in the form of carpopedal spasm of the wrist and ankle joint.
- *Symptoms*—there is stiffness in hands, feet and lips. There is also paresthesia of hand, feet and around the mouth. Tingling in the circumoral area, fingers and toes. Patients may complaint of anxiety, depression, epilepsy and chorea. Reduction in intellectual capacity due to calcification within the brain.
- *Trousseau's sign*—it is elicited by occluding blood flow to the forearm for 3 minutes with sphygmomanometer cuff applied to the arm and raising the pressure above systolic level. This will induce carpopedal spasm.

Oral Manifestations

- *Teeth*—hypoplasia of enamel (**Fig. 36-10**), delayed eruption, external root resorption and root dilacerations. There is also blunting of molar roots.

Fig. 36-10: Enamel hypoplasia in patient with known history of hypoparathyroidism in childhood.

- *Chvostek sign*—a sharp tap over the facial nerve in front of ear causes muscle twitching of facial muscle around the mouth which is called as Chvostek sign.
- *Candidiasis*—chronic candidiasis is also some time present in case when hypoparathyroidism is associated with endocrine-candidiasis syndrome.

Radiographic Features

- *Calcification*—calcification of basal ganglion which appears flocculent and paired with the cerebral hemisphere on PA view.
- *Dental radiographic finding*—radiograph of jaw may reveal enamel hypoplasia, external root resorption, delayed eruption or root calcification.

Diagnosis

- *Clinical diagnosis*—Trousseau's sign, Chvostek sign and features of tetany may diagnose this condition.
- *Radiological features*—calcification of basal ganglion with enamel hypoplasia may give clue to diagnosis.
- *Laboratory diagnosis*—the serum calcium level is decreased usually below 7 mg/dl. Serum phosphate level correspondingly elevated. Urinary calcium is low or absent.

Management

- *Calcium and vitamin D supplement*—supplemental calcium and vitamin D depending on severity of the hypocalcemia and the nature of the associated signs and symptoms.
- *Intravenous calcium gluconate*—in severe cases intravenous administration of calcium gluconate is the treatment of choice.

Pseudohypoparathyroidism

It is also called as 'Albright Hereditary osteodystrophy', 'acrodysostosis'. In this normal parathyroid hormone is present in the body but biochemical pathway responsible for activating target cells are defective in function.

Types

- *Type I*—there are again three subcategories.
 - *Type I a*—molecular defect of intracellular binding protein prevent formation of cyclic adenosine monophosphate (cAMP). This will hamper cell metabolism. This is autosomal dominant.
 - *Type I b*—it is caused by defective receptor for the PTH on the surface of the target cells. It is autosomal dominant trait.
 - *Type I c*—there is defect in adenylate cyclase.

- *Type II*—there is induction of cAMP by PTH in target cells, but function response by the cell is not invoked.

Clinical Features

- *Stature*—patient manifest short stature due to early closure of certain bony epiphysis.
- *Shortened finger*—hand shows shortening of the metacarpal bones, so that finger are short.
- *Osteoma cutis*—subcutaneous calcification may be present in some patient

Oral Manifestation

- *Facial features*—midfacial hypoplasia, The face is rounded in appearance.
- *Teeth*—there is generalized enamel hypoplasia, oligodontia, and delayed eruption of teeth present.

Radiological Features

- *Apices of teeth*—there is blunting of apices of teeth
- *Dagger shaped calcification*—dagger shaped calcification seen in pulp of teeth.
- *Pulp chamber*—widened pulp chamber is present.

Diagnosis

- *Clinical diagnosis*—short stature, osteoma cutis oligodontia is present.
- *Radiological features*—dagger shaped calcification is typical of this disease.
- *Laboratory diagnosis*—elevated serum level of PTH with hypocalcemia, hyperphosphatemia.

Management

- *Vitamin D and calcium*—this can be given to control pseudohyperparathyroidism.

Diseases of Pancreatic Gland

Diabetes Mellitus

It may cause by autoimmune response. Principal laboratory sign are hyperglycemia. It is common endocrine disorders characterized by chronic hyperglycemia and abnormalities in carbohydrate and lipid mechanism. It is caused by disorders of carbohydrate mechanism resulting from insulin deficiency or ineffectiveness, producing hyperglycemia and glycosuria.

Types

- *Type I or Insulin dependent (IDDM)*—it occurs due to deficiency. There is lack of insulin production resulting in severe hyperglycemia and ketoacidosis.

- *Type II or non-insulin dependent (NIDDM)*—it occurs due to insulin resistance. Insulin resistance occurs in type II diabetes is due to an abnormal insulin molecule, an excessive amount of circulating antagonists and target tissue defect.

- Non-obese
- Obese
- Maturity onset diabetes of the young (MODY)

Pathogenesis

Type I diabetes mellitus

- *Increase blood glucose level*—as there is deficiency of insulin glucose will remain in blood as absorption of it is hampered. So blood glucose level is increased.
- *Glucose as main energy source*—as glucose is main source of energy in the body and it can not get absorbed patient feels tired and loosed its weight inspite increased food intake.
- *Polyuria and polydipsia*—due to hyperglycemia, osmolarity of blood and urine increased which will results in frequent urination which again lead to increase in water intake (polydipsia).

Type II diabetes mellitus

- *Decrease in number of insulin receptor*—in this condition there is decrease in number of insulin receptor results in non absorption of glucose in the body. Thus patient show insulin resistance.

Etiology

Type I diabetes mellitus

- *Viruses*—several viruses are been implicated including infection with mumps Coxsackie's B₄, retrovirus, rubella and cytomegalovirus and Epstein-Barr virus. Virus particle known to cause cytopathic or autoimmune damage to beta cells have been isolated from the pancreas.
- *Diet*—bovine serum albumin (BSA) a major constituent of cow's milk has been implicated in triggering type I diabetes. It has been shown that a child who has taken cow's milk early in infancy has been more prone to develop type I diabetes mellitus as compared to other who has taken breast milk.
- *Stress*—it may precipitate the development of type I diabetes by stimulating the secretion of counter regulatory hormones and possibly by modulating immune activity.
- *Immunological factors*—there is evidence that type I diabetes is a T cell mediated autoimmune disease. There is also HLA linked genetic predisposition. Monoclonal cell infiltration of pancreatic islets restoration in selective destruction of insulin secreting cells and induction of remission by immunosuppressive drugs such as cyclosporine suggest its immunological etiology.

Type II diabetes mellitus

- **Genetic**—the majority of cause of type II diabetes are multifactorial. Various types are associated with it like hepatocyte nuclear factor, glucokinase, and mitochondrial DNA and insulin receptors.
- **Environmental factors**
 - **Life style**—overeating, especially when combined with obesity and under activity is associated with developmental of type II diabetes.
 - **Malnutrition**—it is proposed that malnutrition *in utero* and the infancy may damage beta cell development at a critical period predisposing to type II diabetes later in life.
 - **Age**—age is an important risk factors for type II diabetes as it is principally disease of middle aged and elderly affecting 10% of the population over the age of 65.
 - **Pregnancy**—during normal pregnancy, insulin sensitivity is reduced through the action of placental hormone and this affect glucose tolerance. The term gestational diabetes refers to hyperglycemia occurring for the first time during pregnancy.

Clinical Features

- **Polydipsia**—there is excessive intake of fluid.
- **Polyuria**—there is excessive urine passage.
- **Polyphagia**—there is excessive hunger.
- **Breath**—there is presence of acetone breath.
- **Visual activity**—visual difficulty ranging from progressive color blindness to total blindness that have disease more than 20 years.
- **Atherosclerosis**—coronary artery disease and stroke are frequent complication.
- **Diabetic neuropathy**—due to atherosclerosis nerves may get compressed causing marked irritability.
- **Infection**—recurrent vaginal (yeast) infections, recurrent urinary tract infections, recurrent skin infections (especially of feet) and reversible paraesthesia of fingers or toe.
- **Others symptoms**—patient may complaint of nocturia, weight loss, fatigue, obesity, temperature, and hypertension and reduced peripheral pulses.
- **Symptoms of type II diabetes mellitus**—symptoms are very mild in nature with this disease discovered on routine hematological examination.

Oral Manifestations

- **Effect on periodontium**—it will influence the onset and course of periodontal disease. Patient with diabetes are more prone to develop periodontal disease than are those with normal glucose metabolism. As such diabetes mellitus does not cause periodontal disease directly but

it alters the response of the periodontal lesion to local irritants, hastening bone loss and retarding postsurgical healing of the periodontal lesions. Also gingival fluid in the diabetes has more glucose level which favors the growth of microflora.

- **Periodontitis**—the patient may exhibit a fulminating periodontitis (**Fig. 36-11**) with periodontal abscess formation. This will give rise to mobility of teeth. There is severe and rapid alveolar bone resorption takes place. Insulin dependent diabetic children tend to have more destruction around the first molars and incisors than elsewhere.

Fig. 36-11: Severe periodontitis seen in diabetic mellitus patient of type I (Courtesy Dr Soni).

- **Median rhomboidal glossitis**—diabetes is considered to be factor for median rhomboidal glossitis as frequency of abnormal blood sugar level in diabetes is related to occurrence of median rhomboidal glossitis. There is also impairment of blood supply to dorsum of tongue due to arteriosclerotic changes in the blood vessels supplying the area. Impairment of local immune mechanism which decrease the concentration of Langerhans of cells in the lesion.
- **Oral candidiasis**—it is the infection with candida albicans which is occur due to encouragement of local multiplication of candida albicans due to impaired glucose level and immune mechanism.
- **Localized osteitis**—dry socket develops in diabetes hence they show delayed healing and impaired immunological balance.
- **Burning mouth**—it is often associated with variety of otherwise unexplained oral symptoms such as burning sensation, atypical paresis, dysesthesia and dysgeusia.
- **Trigeminal nerve involvement**—diabetes neuropathy is recognized as polymorphic condition as when manifested as polyneuropathy on the assumption that trigeminal nerve might be involved.

- *Xerostomia and increase caries activity*—there is also increased caries activity which results of xerostomia which occur due to excessive fluid loss.
- *Delayed healing*—there is delay in healing of oral wound due to decreased polymorphonuclear chemotaxis.
- *Diabetic sialadenosis*—in diabetic patient there is also diffuse nontender bilateral enlargement of parotid gland.
- *Other features*—there is also angular cheilosis, altered taste sensation, oral lichen planus, and diffuse enlargement of parotid gland.

Radiographic Features

- *Loss of lamina dura with blurring of alveolar crest*—slight discontinuity or blurring of the cortex of alveolar crest to wide destruction of lamina dura.
- *Bone loss*—there is also horizontal and vertical bone loss.

Complications

- *Microangiopathy*—it results in occlusion of small blood vessels producing peripheral vascular disease. This results in decreased tissue perfusion which in turn results in severe infection like gangrene.
- *Coronary artery disease*—vascular occlusion may affect the coronary artery resulting in myocardial infarction, cerebrovascular accident and stroke.
- *Blindness*—when retinal vessels are affected blindness may result.
- *Other complication*—ketoacidosis, premature mortality, and diabetic coma may result.

Diagnosis

- *Clinical diagnosis*—polyuria, polydipsia and polyphagia with periodontal problems may give clue to the diagnosis.
- *Radiological diagnosis*—not specific
- *Plasma glucose concentration*—unequivocal elevation of plasma glucose concentration greater than 140 mg/dl.
- *The glucose tolerance test*—plasma glucose concentration is 200 mg/dl.
- *Taste paper strip*—strips are available for direct estimation of blood glucose level.
- *Blood*—random glucose elevated, fasting glucose elevated, 2 hour postprandial glucose elevated.

Management

- *Diet control*
 - *Balance calorie intake*—the patient with NIDDM, particularly those who are obese, dietary control toward a balanced calorie intake and exercise leading to weight loss is the sole treatment require.
 - *Calories from carbohydrate*—in diabetic patient, it is recommended that the percentage of calories derives

from carbohydrates should be increase and that from fat reduced. A suitable diet for diabetic person—50% of the daily caloric intake should be derived from carbohydrates of which significant amounts should be in the form of non-starch polysaccharides.

- *Mono unsaturated oil*—fat intake should be reduced; the use of mono unsaturated oils in the diet (e.g. olive oil, peanut oil) is beneficial.
- *Other*—reduced intake of sodium (no more than 6 g/day), alcohol abstinence, low calories and sugar free drink are useful for patients with diabetes.
- *Oral hypoglycemic drugs*—if dietary management proves ineffective in controlling hyperglycemia, hypoglycemic drugs like insulin or oral hypoglycemic are prescribe.
 - *Sulfonylurea*—first generation sulfonylurea in which tolbutamide is nowadays is given in a dosage of 25 or 500 mg 8 or 12 hourly. It is useful in the elderly in whom the risk and the consequence of inducing hypoglycemia are increased. In second generation sulfonylurea, gliclazide and glipizide are widely used.
 - *Biguanides*—they are less widely used than sulfonylurea because of their higher incidence of side effects. Mechanism of action is by increasing insulin sensitivity and peripheral blood glucose uptake. Metformin in dose of 500 mg 12 hourly. Its use is contraindicated in persons with impaired renal or hepatic function and in those who take alcohol in excess because of risk of lactic acidosis.
 - *Alfa-glucosidase inhibitors*—they delay carbohydrates absorption in the gut by selectively inhibiting disaccharides. Acarbose is currently available in a dose of 50-100 mg with each meal.
- *Insulin therapy*—insulin was discovered in 1921. The duration of action of short acting unmodified insulin, which is a clear solution can be extended by addition of protamine and zinc at neural pH. Insulin is injected subcutaneously into recommended sites namely anterior abdominal wall, upper arms, outer thighs and buttocks. Short acting insulin has to be injected at least 30 minutes before a meal to allow adequate time for absorption. After giving insulin carbohydrate should be given to patient as blood glucose level may fall drastically and insulin shock may results. Side effects of insulin are hypoglycemia, weight gain, peripheral edema, insulin antibodies, local allergy and lipodystrophy.

Diabetic Insipidus

- *Causes*—it occurs due to insufficiency of the posterior pituitary hormone. Traumatic episodes, such as head trauma or surgical procedures carried out near the

pituitary region, can often lead to destruction of the posterior lobe of the pituitary. In these patients, there is damage to the neurohypophyseal mechanism for the production of vasopressin. Other causes of posterior pituitary disorders leading to diabetes insipidus include tumors like craniopharyngioma, syphilis and basal meningitis.

- **Symptoms**—there is increase thirst and passage of large quantities of urine. Urine is of low specific gravity. There is also dehydration, headache, irritability, and fatigue may be cause of restriction of fluid.
- **Management**—administration of vasopressin is the treatment of choice. Desmopressin can be given intranasal in a dose of 5-10 mg once or twice daily.

Dental Consideration

- **Emergency**—emergency can occur due to diabetes coma or insulin shock. If tolbutamide, chlorpropamide or small doses of insulin is taken by the patient there will be less chances of diabetic coma. However, if the patient takes large daily dose of insulin there is possibility of diabetic coma or insulin shock. If the patient complains of being thirsty, nauseous and shortness of breath and has warm dry skin, the patient is most likely hyperglycemic and should be immediately refer to the physician. No treatment will be required by the dentist.
- **Dental management**—deliver treatment in such a way so as to minimize disturbances of metabolic balance.
 - **Appointment**—appointment should be of short duration and in the morning. Encourage to maintain their standard regimen.
 - **Glucose drink**—glucose drink should be available if patient complains of hypoglycemia.
 - **Local anesthesia without epinephrine**—use local anesthesia without epinephrine in the dental procedure. There is increased incidence of dry socket is due to decreased blood supply to mandible is caused by arteriosclerosis in long standing diabetes. If you are giving epinephrine, it will further reduce blood supply which further increases chances of dry socket.
 - **Suturing**—following extraction suturing of the socket should be done to aid homeostasis.
 - **Physician referral**—physician advice should be taken before arranging general anesthesia for dental treatment.
 - **Antibiotics prophylaxis**—antibiotic prophylaxis before dental surgery to prevent subsequent infection.
 - **Avoid complicated oral procedure**—complicated oral procedure in dental emergencies should be avoided whenever possible in uncontrolled diabetics until stabilization of blood glucose level is achieved.

Diseases of Adrenal Gland

Addison's Disease

It is also called as '*chronic adrenal insufficiency of the adrenal cortex*'. It was first described by Addison in 1855.

Etiology

- **Autoimmune**—sporadic and polyglandular syndrome may cause destruction of adrenal gland. It may be cause by bilateral destruction of the suprarenal glands.
- **Infection**—tuberculosis and some deep fungal infection may cause this disease.
- **Other cause**—metastatic carcinoma, intradermal hemorrhage, amyloidosis, hemochromatosis, adrenal infarction and congenital adrenal hypoplasia may be the causative factors.
- **Drugs** which can cause Addison's disease are aminoglutethimide, ketoconazole and etomidate.

Clinical Features

- **Age and sex**—it is more common in males and, while found in all age groups, it is most frequently seen in the 3rd and 4th decade.
- **Symptoms**—feeble heart action, general debility, vomiting, and diarrhea and severe anemia. Patient complains of postural hypotension. There is also reduced resistance to infection, trauma, and stress.
- **Sign**—the disease is characterized by bronzing of skin, a pigmentation of the mucous membrane.
- **Metabolic function**—decrease cortisol level interferes with the manufacture of carbohydrates from protein, causing hypoglycemia and diminished glycogen storage in the liver.
- **Neuromuscular function**—neuromuscular function is inhibited, producing muscle weakness.

Oral Manifestation

- **Bronze pigmentation**—the pale brown or deep chocolate pigmentation of the oral mucosa, spreading over the buccal mucosa from the angle of the mouth and/or developing on the gingiva, tongue (**Fig. 36-12**), and lips may be first evidence of disease.

Diagnosis

- **Clinical diagnosis**—bronze skin and bronze pigmentation in oral cavity, decreased metabolic function may give clue to the diagnosis.
- **Laboratory diagnosis**—biopsy of oral lesion show acanthosis with silver positive granules in the cells of the stratum germinativum. Anemia is normocytic and normochromic associated with reticulocytosis. High blood levels potassium and low concentration of sodium and chloride. There is also elevated blood urea nitrogen

Fig. 36-12: Diffuse pigmentation seen on tongue in patient with Addison's disease.

Management

- *Glucocorticoids replacement*—cortisol is the drug of choice. In patient who are not critically ill hydrocortisone 15 mg on waking and 5 mg at 6 pm in evening.
- *Supplement Mineralocorticoids*—it can also be given.

Adrenogenital Syndrome

It refers to any situation in which there is overproduction of androgens. It results when hyperplasia or tumors of the adrenal cortex occur. It may appear at 3 different times of life, i.e. at birth, in childhood and in adult. Clinical features vary according to appearance of lesion.

- *At birth*—in female child it produces pseudohermaphroditism, while in male child it produces macrogynitosomia praecox.
- *In childhood*—in the females it produces masculinization and in males it produces sexual precocity.
- *In adults*—in females it produces virilism and in males it produces feminization.

If the disease begins early premature eruption of the teeth may occur. This disease managed by administration of corticosteroid or estrogen.

Cushing's Syndrome

Cushing's syndrome arises from excess secretion of glucocorticoids by the adrenal glands. It is described by Harvey Cushing in 1932.

Etiology

- *Adrenal tumor*—Cushing's syndrome is caused by adrenal adenoma, adrenal carcinoma, adrenal hyperplasia and basophilic adenoma of the anterior lobe of pituitary gland.

It can also be caused by ACTH secreting tumor of the anterior pituitary which is associated with adrenal cortical hyperplasia.

- *Administration of corticosteroid*—in some cases administration of exogenous corticosteroid may lead to this condition.
- *Ectopic*—ectopically located adrenal like tumor, e.g. in ovary may cause these conditions.
- *Other*—alcohol excess, major depressive illness and primary obesity.

Clinical Features

- *Age and sex*—female to male ratio is 3:5, seen in 3rd and 4th decades.
- *Symptoms*—patient may complain of weight loss, menstrual irregularity, hirsutism, backache, obesity, and hypertension.
- *Moon face*—rapidly acquired obesity about upper portion of the body due to abnormal deposition of fat will result in moon facies (Fig. 36-13).

Fig. 36-13: Rounded moon facies seen in Cushing's syndrome (Courtesy Dr Milind Chandurkar).

- *Buffalo hump*—there is truncal obesity with prominent supra-clavicular and dorsal cervical fat pads giving rise to the 'buffalo hump' appearance at the base of neck.
- *Purple abdominal striae*—dusky plethoric appearances with formation of purple striae appear on abdomen (Fig. 36-14).
- *Others feature*—thin distal extremities, concurrent diabetes and alternation in hair distribution can also be present.

Oral Manifestations

- *Dental age*—in children growth and development including skeletal and dental age may be retarded.

Fig. 36-14: Purple abdominal striae seen on abdomen in Cushing's syndrome (Courtesy Dr Milind Chandurkar).

Radiographic Features

- *Osteoporosis*—generalized osteoporosis is present. The bone likely to involve are the vertebrae and the ribs although the long bones may be affected.
- *Demineralization*—there is osseous demineralization with pathological fractures, often superimposed.
- *Skull*—it may show diffuse thinning and have mottled appearance.
- *Lamina dura*—jaw may show areas of loss of lamina dura.

Diagnosis

- *Clinical diagnosis*—moon facies, buffalo hump, purple striae on abdomen will easily diagnosed this condition.
- *Radiological features*—generalized osteoporosis with loss of lamina dura may give clue to diagnosis.
- *Laboratory diagnosis*—this is done by measuring serum ACTH and cortisol level after administration of dexamethasone. In normal patient this level will be decreased but it is unaffected in patient with Cushing's syndrome.

Management

- *Surgery*—tumors involving the adrenal cortex are removed surgically and often require postoperative administration of corticosteroids to maintain normal glucocorticosteroids level.
- *Radiotherapy*—in case of Cushing's syndrome due to adrenocortical hyperplasia, pituitary irradiation is the best treatment.
- *Drugs used*—metyrapone in dose of 2-6 gm per day in divided doses by mouth. Other drug given is *aminoglutethimide*, *ketoconazole* which act by blocking steroid synthesis.

- *Prevention*—when corticosteroid is prescribed lowest dose should give to patient to manage the immunological disease.

Adrenal Insufficiency

It is relatively rare and usually occurs in connection with an acute septicemia and is called as *Waterhouse-Friderichsen syndrome*. This occurs in patient who are on long-term steroid for the treatment of variety of systemic condition developed adrenal insufficiency.

Types

- *Primary*—it occurs due to disorders of pituitary or adrenal glands (primary adrenal insufficiency is called as Addison's diseases).
- *Secondary*—it occurs due to chronic administration of corticosteroid resulting in the suppression of endogenous steroid.

Etiopathogenesis

- *Sudden withdrawal of steroid*—it usually occur following sudden withdrawal of steroid hormones in a patient who has primary adrenal insufficiency. Following sudden withdrawal in a patient with normal adrenal cortices but with a temporary insufficiency resulting from cortical suppression by exogenous corticosteroid administration
- *Following stress*—following stress such as physiologic or psychological stress.
- *Bilateral adrenalectomy*—following bilateral adrenalectomy or removing of a functioning adrenal tumor that had been suppressing the other adrenal gland.
- *Destruction of pituitary gland*—following sudden destruction of the pituitary gland.
- *Trauma*—following injury to both adrenal glands by trauma, hemorrhage, infection, thrombosis or tumor.

Clinical Features

- *Age*—it occur primarily in children but can occur in adults.
- *Onset*—it is characterized by rapidly fulminating septic course, a pronounced purpura and death within 48 to 72 hours.
- *Symptoms*—in this, patient is not able to tolerate the stress. There is anxiety, fatigue, hypotension, abdominal pain, nausea, vomiting, cold clammy skin, lethargy, and partial or complete loss of consciousness. There is also mental confusion occur in acute adrenal insufficiency.
- *Sign*—oral, conjunctival, and vaginal mucosae often show patches of pigmentation. In some patient, particularly in the dark-skinned races, patchy area of

depigmentation surrounded by hyperpigmentation may be seen. Hyperpigmentation of buccal or labial mucosa is seen in many patients. These patches may be brown, gray or blue in color.

Oral Manifestations

- *Early eruption*—teeth may erupt early, compared with the normal, but the eruption is in harmony with the skeletal age.

Diagnosis

- *Clinical diagnosis*—stress intolerance, mental confusion and hyperpigmentation of buccal and labial mucosa will give clue to the diagnosis.
- *Laboratory diagnosis*—plasma cortisol levels are low and fail to raise after administration of ACTH. Plasma ACTH levels are elevated and serum sodium and chloride and urinary 17-ketosteroid and 17-hydroxy-corticosteroids are low.

Management

- *Replacement therapy*—it is given in combination of glucocorticoids (cortisol), mineralocorticoids (fludrocortisone), and anabolic steroids. In mild case, hydrocortisone alone might be sufficient.

Dental Considerations

- *Defer the treatment*—if the adrenal crisis occurs during the treatment further dental treatment should be stopped.
- *Position of patient*—put patient in shock position.
- *Airway maintenance*—maintain the patency of the airway and administer oxygen.
- *Physician consultation*—you should call physician for further management.
- *Saline*—start intravenous 5% dextrose saline.
- *Hydrocortisone*—administer 100-200 mg of hydrocortisone.
- *Sodium succinate*—sodium succinate intravenously should be given.

Prevention

- *History*—a careful history should be taken if the patient has been using steroids on long-term basis.
- *Additional steroid dose*—such patients should be administered additional dose of steroids prior to surgery such that dose is increased to double or triple level 2 to 3 days preceding the surgery. Then it should be gradually taper to the maintain level. Patient who has been on steroid therapy but presently is off this therapy for the last one year without any adverse effects, needs no steroid supplementation.

- *Physician consultation*—consult the physician to determine the suitable dose during the pre, intra, and postoperative phase.

Diseases of Gonads

Hypergonadism

If occurring in children, results in precocious puberty. The long bone develops quickly and child may initially turn toward tallness, but this is offset by the early fusion of the epiphyses so that adult's person may be short.

Hypogonadism

It occurs in equal frequency in males and females. The bones are long and slender and epiphyses are late in fusion. The supraciliary ridges, malar bone and the mandible show greater development.

The chin is pointed, the palate is high and markedly arched and irregularities of the teeth occur. The mandible tends to become enlarged and even massive with short rami in male hypogonadism.

The skull is small and there is marked or even excessive enlargement of the frontal and sphenoid sinuses and especially mastoid air sinus.

Pregnancy

Pregnancy cause physiologic changes throughout that are of relevance to dentist. Alteration in the level of circulating female sex hormone modified the response of periodontium. During pregnancy there are carious hormonal change leading to an increased blood volume, cardiac output, glomerular filtration rate and O₂ requirement.

- *First trimester*—during 1st trimester, there is persistence nausea and vomiting and morning sickness due to carbohydrate starvation and ketosis.
- *Third trimester*—during 3rd trimester as a response to emotional and physical stress of the treatment, large quantities of the steroid are liberated into bloodstream. The pituitary secretes oxytocin which can stimulate uterine contraction and hence premature labor.
- *Pregnancy gingivitis*—One of the most common oral complications seen with pregnant women is called pregnancy gingivitis. This condition presents as fiery red swollen gums. It usually begins in the second month of pregnancy and progresses throughout the pregnancy. It is the result of an exaggerated inflammatory response of the gums to bacteria, plaque and calculus in the mouth, due to an increase of estrogen and progesterone hormones in the pregnant woman. In pregnancy gingivitis, like regular gingivitis, the gum

tissue may bleed more easily than normal. After pregnancy these conditions should return to normal with proper oral hygiene.

- **Diabetes**—women can get gestational diabetes (hyperglycemia occurring for first time during pregnancy). Repeated pregnancy can increase likelihood of developing permanent diabetes particularly in obese women. Pregnancy in diabetic women is associated with increased perinatal mortality rate.
- **Epilepsy**—epilepsy may worsen during the pregnancy particularly during the 3rd trimester when plasma anti-convulsant levels tend to fall frequently, monitor blood level during pregnancy.

Dental Management

- **Routine dental procedure**—scaling and prophylaxis should be performed as often as is necessary to control local etiologic factors and reduce gingival inflammation. Second trimester is the safest period during which to perform routine dental care. Stressful procedure should be avoided during pregnancy. In a pregnant woman stress and strain involved can lead to complication during the treatment.
- **Radiograph**—dental radiographs or X-rays are not used for routine dental care. In emergency situations, X-rays may be needed to diagnose a problem, however proper safety measures should be taken. These measures include the lead apron, reduced radiation and the X-ray beam position. This again is most important in the first trimester.
- **Drugs**—we must also modify drugs that can be administered to the pregnant or breastfeeding patient. Certain anesthetics, pain relievers, antibiotics, and sedative drugs that may be used are considered unsafe for the developing fetus and must be avoided. For breastfeeding mothers there is concern over certain drugs that may be absorbed into the mother's milk. The local anesthetic that we use is considered safe for emergency dental care needs.
- **Syncope**—if syncope develops turning the patient on left side will relieve the pressure and put the patient back to normal. Supine position can lead pressure on inferior vena cava by the fetus leading to poor venous return and lead to hypotension further aggravating the condition.
- **First and third trimester**—all planned surgical procedures should be avoided in the 1st and 3rd trimester to avoid fetal stress and premature labor. This is because of the vulnerability of the growing fetus in the first 3 months or trimester and the comfort level of the mother in the last trimester. Third trimester dental care is best postponed due to the comfort level of the patient and to avoid supine

hypotension syndrome. This is a compression of the large vein in the abdomen, the inferior vena cava, which brings blood back to the heart. Unfortunately, lying on your back in the dental chair can cause this compression. Also, there is always the risk of the patient going into labor and dentists are not very good at delivering babies.

- **Precaution**—the best measure that the pregnant women can take is prevention. This consists of diligent brushing and flossing to remove plaque from the teeth and gums along with annual dental check-ups and cleanings. By maintaining a healthy oral environment, you can minimize the need for emergency dental treatment during your pregnancy.

Menopause

It begins when menstrual function ceases and it usually occur between the ages 40 to 55. There are numerous symptoms associated with it and they are caused by deficiency of estrogen.

Irritability, insomnia, nervousness, osteoporosis, back and joint pain can also occur in menopause. Patient may complaint of burning mouth and tongue, taste abnormalities and dryness of the mucous membrane are also present. There may be desquamative gingivitis in which there is atrophy and ulceration of the gingival tissue and bleeding.

Treatment consists of estrogen replacement therapy depending on the symptoms.

Introduction

The cellular elements of the blood as well as its plasma proteins play an extraordinary role in many physiologic mechanisms of the body. The circulating blood has a profound effect on the maintenance of normal oral mucous membrane, especially in the mucosa of tongue.

Many important disorders of blood present with symptoms and signs are seen in the oral cavity. The dentist is frequently the first medical personnel to encounter such disorders.

Physiology of Blood

Blood is unique bright red (arterial) to dark red (venous) colored liquid of variable composition, circulating through the vessels of body.

It participates in all physiologic and pathologic activities in all organs and is composed of liquid called as '*plasma*' in which there are suspended erythrocytes, leukocytes and thrombocytes collectively called as '*hemocytes*'.

If blood is allowed to clot, an amber colored liquid remains after the separation of the clot and is known as '*serum*'. It differs from plasma only by the loss of protein fibrinogen, which is removed in the coagulation process.

Composition

Blood is a highly complex fluid, which is composed of two parts liquid plasma (55%) and different types of cells (45%).

- *Cells*—it consists of red blood cells or corpuscles or erythrocytes, white blood corpuscles or leukocytes and platelets or thrombocytes
- *Water*—it is about 91 to 92%.
- *Solid*—it consists of sodium, potassium, calcium, magnesium, phosphorus, iron, copper, etc.—0.9%.

Serum albumin, serum globulin, fibrinogen—7.5%. Nonprotein nitrogenous substances like urea, uric acid, carbohydrates, fats, etc. Various enzymes like amylase, protease and lipase are also present. The yellow color of plasma is due to bilirubin and carotene.

Plasma Proteins

In normal circumstances, total amount of plasma proteins varies from 6.5 to 7.5% and an average of 7%.

Composition

- *Serum albumin*—4.7 to 5.7%
- *Serum globulin*—1.8 to 2.5%
- *Fibrinogen*—0.2 to 0.4%
- *Prothrombin*—0.1 %

Functions of Plasma Proteins

- *Blood clotting*—they are essential for blood clotting.
- *Antibodies*—the antibodies are globulin in nature and are essential for defence against infection.
- *Transport*—they also help in transport of certain substances in blood like hormones and enzymes.
- *Osmotic pressure*—it maintains colloidal osmotic pressure of blood and concerned with erythrocyte sedimentation rate (ESR).
- *Buffer*—they act as a buffer in maintaining acid-base balance, as a protein reservoir.
- *Trephones*—the leukocytes prepare substances from plasma proteins which are necessary for nourishment of tissue cells.

Some Facts about Blood

- *Blood volume*—the total blood volume in the circulation as well as blood in stores is about 5 liters or 90 ml per kg of body weight.

- *Specific gravity of blood*—1.052 to 1.063 and primarily depends upon the ratio of plasma to red cells.
- *Viscosity of blood*—the relative viscosity of water, plasma and whole blood are roughly 1, 1.8 and 4.7.
- *pH*—the pH of blood varies between 7.36 and 7.45, the average is about 7.4.

Red Blood Corpuscles (Erythrocytes)

It was first described by Dutch microscopist *Leeuwenhoek* in 1674. It lacks cytoplasmic organelles such as nucleolus, mitochondria and ribosomes. It is unable to synthesize new proteins and carry out the oxidative mechanisms associated with mitochondria or undergo mitosis. They are produced in liver, spleen and lymph nodes in embryonic life and after birth; they are produced exclusively in the bone marrow.

Factors Controlling Erythropoiesis

- *Diet*—food rich in first class proteins is important as they supply essential amino acids for the synthesis of globulin for hemoglobin.
- *Tissue oxygenation*—any condition leading to decreased oxygen in the tissues increases the rate of RBC production, e.g. anemia, high altitude, prolonged cardiac failure and lung disease.
- *Erythropoietin stimulating factor*—it is a circulating hormone which is formed in the kidney.
- *Vitamins*—vitamin B₁₂ which is required for DNA synthesis and folic acid which is required for conversion of pre-erythroblast into early normoblast. Vitamin C and B₆ are also important factors.
- *Metals*—iron for hemoglobin formation; copper, magnesium and cobalt for conversion of iron into hemoglobin by catalytic action and calcium which help indirectly by conserving iron and its subsequent assimilation.
- *Bile salts*—they are required for proper absorption of metals.

Composition and Morphology of RBC

- Each cell is composed of a colorless envelope consisting of 65% water and 35% solids of which 33% is hemoglobin bound to 2% stromal network.
- *Shape and size*—normal RBC is biconcave disc having a mean diameter of approximately 6.9-7.4 microns. The shape of RBCs can change remarkably as the cell passes through the capillaries.
- *RBC count*—the normal RBC count in an adult male is taken as 5 to 5.4 million/mm³ cells per cu mm and in adult females, 4.5 to 4.8 million/mm³. In infants, the count is 6 to 7 millions/mm³ where as in fetus it is 7 to 8 million/mm³.

- *Variations in RBC count occur in the following physiological conditions*—the count is lowest during sleep, then gradually rises and becomes maximum in the evening. Also muscular exercise, high altitude and high external temperature lead to reduced oxygen tension in arterial blood; injection of adrenaline and excitement increase the RBC count.
- *Life span*—the average life span of a mature red cell is about 120 days. As the cells become senile, they become flask-shaped and become more brittle, then get fragmented and are swallowed up by the RE cells. Hemoglobin is released and broken down into heme and protein.

Functions of RBC

- *Respiratory*—they carry oxygen and carbon dioxide.
- *Acid base balance*—they help to maintain the acid base balance.
- *Viscosity*—they maintain the viscosity of blood.
- *Pigment*—various pigments are derived from hemoglobin after disintegration of RBCs.

Hemoglobin

It is a red conjugated protein. The hemoglobin molecule is roughly spherical in shape, consisting of two pairs of polypeptide chains to which a highly colored heme group, which is a complex of iron and protoporphyrin, is added. The protein portion of the molecule is called globin.

Functions of Hemoglobin

- *Oxygen carriage*—it is essential for oxygen carriage. It combines easily with oxygen to form oxyhemoglobin. Oxyhemoglobin holds oxygen loosely which can be easily displaced by many other gases like CO, CO₂, H₂S, etc. to form a more stable compound.
- *Carbon dioxide transport*—it helps in carbon dioxide transport by directly combining with CO₂ to form a carbamino compound.
- *Acid base balance*—it constitutes one of the important constituents of blood and helps in maintaining acid base balance of blood.
- *Pigment*—various pigments of bile, stool, urine, etc. are formed from it.

White Blood Corpuscles (Leukocytes)

They are the mobile units of the body's defence system. They are formed partially in the bone marrow and partially in the lymph tissue. After formation, the blood and the lymphatics transport them to different parts of the body. They are nucleated cells with hemoglobin. Leukocytes are rich in nucleoproteins and contain lipids, glycogen,

cholesterol, ascorbic acid and a variety of enzymes, especially proteolytic.

The average total number of WBCs, 6000 to 8000 cells per cu mm, the normal range being 4000 to 11000 cells per cu mm. Life span of WBC is about 2-4 days to about 12-15 days.

Physiologic Variations

Physiologic variations in WBC count occur due to

- *Diurnal variation*—in the morning or after rest the count is the lowest, which rises after mid-day and usually becomes highest in the evening.
- *Exercise*—muscular exercise and injection of adrenaline increases the count.
- *Age*—in a newborn, the count is very high, i.e. about 20,000 cells per cu mm.
- *Relation with pregnancy and labor*—in pregnancy and full term, the count is higher being highest during labor, i. e. 17,000 cells/mm³. There is also an increase during menstruation.

Types of WBC

- *Granular leukocytes or granulocytes*—it consist of neutrophils—62-70%, eosinophils—1-4% and basophils 0-1%.
- *Agranular leukocytes or agranulocytes*—it consist of lymphocytes (25 to 30%)—they are of two types, i.e. small lymphocytes and large lymphocytes and monocytes—5 to 10%.

Functions of WBC

- *Phagocytosis*—the neutrophils and the monocytes engulf and digest foreign bodies and bacteria.
- *Defensive mechanisms*—leukocytes play an important role in the defensive mechanism of the body by manufacturing fraction of serum globulin and formation of fibroblasts.
- *Trephones*—leukocytes manufacture trephones which have great influence on nutrition, growth and repair of tissue.
- *Heparin*—secretion of heparin which prevents intravascular clotting.
- *Anti-histaminic function*—it defends against allergic reactions.
- *Formation of fibroblasts*—lymphocytes may be converted into fibroblasts in areas of inflammation.

Platelets or Thrombocytes

They are non-nucleated, round or oval bi-convex discs having an average size of about 2.5 microns and are covered by a unit membrane. The average number of platelets in a

normal adult varies from 2,50,000 to 4,50,000 per cu mm. Vigorous muscular exercise, high altitude and hypoxia increase the platelet count.

Functions of Platelet

- *Hemostasis and blood clotting*—when there is bleeding, platelets disintegrate and liberate thromboplastin and 5-hydroxytryptamine. Thromboplastin activates prothrombin to form thrombin whereas 5-hydroxytryptamine has a vasoconstrictor effect and thus help in hemostasis.
- *Repair*—In circulation, platelets adhere to the damaged endothelial lining of the capillaries and thus bring about speedy repair.
- *Hasten clot retraction*—speed of clot retraction is directly proportional to the number of platelets present.

Blood Coagulation

When blood is shed, it loses its fluidity in few minutes and sets into semisolid jelly; this process is called as coagulation or clotting of blood.

Clotting Factors

- *Factor I or fibrinogen*—during clotting, fibrinogen is converted to fibrin to form clot.
- *Factor II or prothrombin*—during clotting, prothrombin is converted to thrombin by thromboplastin.
- *Factor III or thromboplastin*—it is essential for conversion of prothrombin into thrombin.
- *Factor IV calcium*—it is essential for the formation of both, intrinsic and extrinsic thromboplastin and also in the conversion of prothrombin to thrombin.
- *Factor V or labile factor or accelerator globulin or proaccelerin*—it is necessary for complete conversion of prothrombin into thrombin by extrinsic or intrinsic thromboplastin.
- *Factor VI or accelerin*—it is hypothetical activation product of proaccelerin.
- *Factor VII or stable factor*—factor X is converted to activated factor X by tissue thromboplastin released following tissue trauma, in the presence of factor VII for extrinsic pathway.
- *Factor VIII or anti-hemophilic factor or anti-hemophilic globulin or platelet cofactor*—it helps in the formation of intrinsic thromboplastin and prothrombin conversion.
- *Factor IX or Christmas factor or plasma thromboplastin component or platelet cofactor II*—it is necessary for intrinsic thromboplastin formation.
- *Factor X or Stuart factor*—it has properties similar to factor VIII.

- *Factor XI or plasma thromboplastin antecedent*—it is activated by active Hageman factor and ultimately leads to the formation of thrombin.
- *Factor XII or Hageman or surface factor*—it activates factor XI.
- *Factor XIII or fibrin stabilizing factor*—it, along with calcium ions convert soft fibrin clot into a solid fibrous one.

Mechanism of Blood Coagulation (Figs 37-1A to C)

The general mechanism takes place in three essential steps:

- *Thromboplastin release*—there is release of thromboplastin due to disintegration of platelets, when they come in contact with rough water, wettable surface and is also released from the damaged tissue.
- *Conversion of prothrombin into thrombin*—prothrombin activator catalyzes the conversion of prothrombin into thrombin.
- *Formation of clot*—thromboplastin acts as an enzyme for converting fibrinogen into fibrin threads that enmesh the blood cells and plasma to form the clot itself.

Blood Group

Human beings may be put into four group according to the nature of the agglutinogens possessed by their RBC. These are called as A, B, AB and O (if no agglutinin is present).

There are different types of Rh antigens each of which is called as Rhesus (Rh) factor. These types are designated as C, D, E. If D antigen is prominent, the person is said to be Rh positive.

Fig. 37-1A

Fig. 37-1B

Fig. 37-1C

Figs 37-1A to C: A diagrammatic representation of mechanism of blood coagulation.

A person who has no D but instead has only C and E antigen is said to be Rh negative.

Diseases of Red Blood Cells

Anemia

It is an abnormal reduction in the number of circulating red blood cells, the quantity of hemoglobin and the volume of packed red cells in a given unit of blood.

Symptoms in a patient with anemia depend on following five factors:

- *Oxygen carrying capacity*—the reduction in the oxygen carrying capacity of the blood.
- *Total blood volume*—the degree of changes in total blood volume.
- *Rate*—the rate at which the above two have developed.
- *Capacity of cardiovascular and respiratory system*—the capacity of the cardiovascular and respiratory system to compensate for anemia.

Classification (Tables 37-1 to 37-3)

Anemia can be classified on the basis of etiology and morphology. Some of important anemias are described below.

Posthemorrhagic Anemia

The anemia caused by blood loss may occur in variety of conditions causing bleeding.

Types

- *Acute*—when blood loss occurs in large amounts in a short period of time, anemia may develop even though iron stores remain adequate. It is called as acute post-hemorrhagic anemia.
- *Chronic*—this develops when there is chronic blood loss in small amount over prolonged period of time and is due to depletion of iron in body. Other findings are the same as that of iron deficiency anemia.

Clinical Features

- *Factors affecting the clinical features*—the manifestations of hemorrhagic anemia depend on the rate and magnitude of bleeding; the time elapsed since it took place and the site—whether it is external or internal.
- *Blood loss (500 to 1000 ml)*—when the blood loss is about 500 to 1000 ml, most of the patients do not present any symptoms, but few may present with weakness and sweating.
- *Blood loss (1000 to 1500 ml)*—with rapid loss of 1000 to 1500 ml, a previously healthy individual may experience lightheadedness and hypotension.

Table 37-1: Classification of anemia (according to etiology)

Loss of blood

- Acute posthemorrhagic anemia
- Chronic posthemorrhagic anemia

Excessive destruction of RBCs

- *Extracorporeal causes*
 - Antibodies
 - Infections like malaria
 - Splenic sequestration and destruction
 - Associated diseases like lymphomas
 - Drugs, chemical and physical agents
 - Trauma to RBC
- *Intracorporeal hemolytic diseases*
 - *Hereditary*
 - Disorders of glycolysis
 - Faulty synthesis or maintenance of reduced glutathione
 - Qualitative or quantitative abnormalities in the synthesis of globulin
 - Abnormalities in RBC membrane
 - Erythropoietic porphyria
 - *Acquired*
 - Paroxysmal nocturnal hemoglobinuria
 - Lead poisoning

Impaired blood production resulting from deficiency of substances essential for erythropoiesis

- Iron deficiency
- Deficiency of vitamin B₁₂, folic acid (pernicious anemia and megaloblastic anemia)
- Pyridoxine responsive anemia
- Protein deficiency
- Ascorbic acid deficiency

Inadequate production of mature erythrocytes

- *Deficiency of erythroblast*
 - *Aplastic anemia* (atrophy of bone marrow)
 - Chemical or physical agents
 - Hereditary
 - Idiopathic
 - Pure red cell aplasia (isolated erythroblastopenia)
 - Thymoma
 - Chemical agents
 - Antibodies
- *Infiltration of bone marrow*
 - Leukemia
 - Multiple myeloma
 - Carcinoma
 - Sarcoma
 - Myelofibrosis
- *Endocrine abnormalities*
 - Myxedema
 - Addison's disease (adrenal insufficiency)
 - Pituitary insufficiency
 - Hyperthyroidism
- *Chronic renal failure*
- *Chronic inflammatory disease*
 - Infectious
 - Noninfectious including granulomatous and collagen disease
- *Cirrhosis of liver*

Table 37-2: Morphologic classification of anemia

Type of anemia	Description	Most common causes
Macrocytic	Increased MCV, MCH and normal MCH conc.	Lack of erythrocyte maturing factors
Normocytic	Reduction only in RBC membrane; normal MCV, normal MCH and normal MCH conc.	Hemorrhage, hemolysis lack of blood formation, dilution of blood with fluid
Simple microcytic	Reduced MCV, MCH, MCH conc.	Associated with infections and inflammatory diseases
Hypochromic microcytic	Reduced MCV, MCH, MCH conc.	Iron deficiency

Table 37-3: Third classification

Anemias with disturbed iron metabolism
• Iron deficiency anemia
• Sideroblastic anemia
Megaloblastic anemia
• Pernicious anemia (vitamin B ₁₂ deficiency)
• Folic acid deficiency
Anemia associated with chronic disorders
• Anemia of chronic infection
• Anemia of inflammatory connective tissue disorders
• Anemia associated with malignancy
• Secondary to chronic bleeding
• Myelophthisic anemia
• Anemia of uremia
• Anemia of endocrine failure
• Anemia of liver disease
• Hemolytic anemia
• Extrinsic causes
• Splenomegaly
• Red cell antibodies
• Trauma in the circulation
• Direct toxic effects
• Membrane abnormalities
• Spur cell anemia
• Paroxysmal nocturnal hemoglobinemia
• Hereditary spherocytosis
• Hereditary elliptocytosis
• Disorders of interior of the red cell
• Defects in the Embden-Meyerhof pathway
• Defects in the hexose monophosphate shunt
Disorders of hemoglobin
• Sickle cell anemia
• Thalassemia

- **Blood loss (1500 to 2000 ml)**—when 1500 to 2000 ml of blood is lost, symptoms like sweating, thirst, shortness of breath, clouding or loss of consciousness are seen. The pulse becomes rapid and low in volume, skin become cold and clammy and there is a fall in blood pressure.
- **Blood loss > 2000 ml**—when rapid loss of blood exceeds 2000 to 2500 ml, severe state of shock is reached.

Diagnosis

- **Clinical diagnosis**—history of blood loss with features of anemia may diagnose this condition.
- **Laboratory diagnosis**—plasma volume and red cell mass are reduced in proportional amount. Anemia is

normocytic and normochromic. Erythropoietin secretion is stimulated which in turn gives rise to hyperplasia of marrow erythroid elements within 3 to 5 days. There is increased in reticulocyte number. Neutrophilic leukocytosis often follows hemorrhage and maximum after 2-5 hours.

Management

- **Restoration of blood volume**—blood transfusion should be given to restore blood volume.
- **Other therapy**—intravenous infusion of saline, dextrin, albumin or plasma.

Iron Deficiency Anemia

Iron is essential for synthesis of 'heme' portion of hemoglobin. Iron deficiency anemia is caused by imbalance between iron intake and loss or inadequate utilization.

Causes

- **Inadequate intake**—inadequate intake of iron in the diet may lead to deficiency.
- **Malabsorption**—malabsorption of iron due to hypochlorhydria and diarrhea may lead to deficiency state.
- **Increase requirement**—increased requirement of iron in a growing child and in pregnancy.
- **Increases loss**—increased loss of iron due to injury, recurrent epistaxis and peptic ulcer. Chronic blood loss such as menstrual and menopausal bleeding parturition.
- **Gastrotomy**—subtotal or complete gastrotomy may cause iron deficiency anemia.

Stages of Iron Deficiency

- **Prelatent iron deficiency**—in this, body storage of iron are depleted but the circulating hemoglobin and serum iron remain within the normal limit.
- **Latent iron deficiency**—in it, body storage of iron are exhausted and serum iron is reduced. The hemoglobin concentration remains unaffected.

- *Early anemia*—the third stage is iron deficiency anemia in which the hemoglobin concentration is reduced in peripheral blood. The serum iron is low.
- *Marked anemia*—in this, hemoglobin concentration is below 10 g per 100 ml of blood. Red blood cells show morphological changes in this stage.

Clinical Features

- *Age and sex*—it occurs chiefly in women in the 4th and 5th decades of life.
- *Symptoms*—the patient experiences tiredness, headache, paresthesia and lack of concentration.
- *Koilonychia*—nails become brittle, flattened and often show spoon shape (koilonychia).
- *Neuropathy*—there may be tingling and pins and needle sensation in the extremities.
- *Dysphagia*—some patients develop pharyngeal mucosal thickening and mucosal web formation, giving rise to dysphagia.
- *Gastrointestinal symptoms*—liver and spleen may be palpable. There may be gastrointestinal bleeding and menorrhagia there by setting a vicious circle.
- *Knuckle pigmentation*—patient may get knuckle pigmentation (pigmentation seen on dorsum of hand at metacarpophalangeal joint (**Fig. 37-2**).

Fig. 37-2: Knuckle pigmentation seen on dorsum of hand at metacarpophalangeal joint

- *Sideropenic anemia*—in certain pathological conditions, iron gets accumulated in mitochondria and appears as a ring of granules round the nucleus. These are called as ring sideroblasts and are the characteristic cells of sideropenic anemia which is either hereditary or acquired. Acquired type can be associated with rheumatoid arthritis, malignant diseases, pernicious anemia and myxedema. Clinical features are same as those of iron deficiency anemia.

Oral Manifestations

- *Pallor of mucosa*—in iron deficiency there is pallor of oral mucosa and gingiva. The normal pink color is lost due to lack of oxygenated blood in the capillary bed in lamina propria and is associated with lowered levels of hemoglobin.
- *Atrophy of oral mucosa*—the generalized atrophy of oral mucosa both in tongue and buccal mucosa occurs.
- *Tongue changes*—there is redness, soreness or burning of tongue. The filiform papillae over the anterior two thirds of tongue are the first to undergo atrophy (**Fig. 37-3**). In severe cases, fungiform papillae are also affected leaving the tongue completely smooth and waxy or glistening in appearance (**Fig. 37-4**).

Fig. 37-3: Atrophy of tongue papillae seen in iron deficiency anemia (Courtesy Dr Milind Chandurkar).

Fig. 37-4: Pallor of tongue with bald appearance seen in iron deficiency anemia (Courtesy Dr Milind Chandurkar).

- *Angular cheilitis*—there is cracking and fissuring at the corner of mouth.
- *Ulceration*—there is softening of epithelium which leads to linear ulceration of the skin, extending up to and beyond the mucocutaneous junction. There may be pain or bleeding from ulcerated tissues. Recurrent aphthous ulceration and candidal lesions can also occur in iron deficiency anemia.
- *Slow healing*—patient may show slow healing after oral surgical procedures.
- *Gingival enlargement*—in some cases, there may be gingival enlargement.

Diagnosis

- *Clinical diagnosis*—koilonychia, neuropathy, angular cheilitis and depapillation of tongue may yield in diagnosis.
- *Laboratory diagnosis*—the anemia is microcytic and hypochromic and the peripheral smear show abnormal forms of RBCs. There is reduced hemoglobin level, as low as 4g/100ml. There is normal or slightly reduced RBC count. MCV, MCH and MCHC are all reduced.

Management

- *Iron supplement*—almost all patients can be treated by oral supplements of iron by giving ferrous fumarate or ferrous sulphate. It is given in dose of 300 mg three to four times a day for a period of 6 months. The parenteral route of administration is suitable for few patients who are unable to take iron by mouth or who are unable to absorb iron by mouth. The recommended single dose of iron sorbitol is 1.5 mg of iron per kg of body weight, given daily.

Plummer-Vinson Syndrome

It is also called as *Paterson-Brown-Kelly syndrome*. It is characterized by dysphagia, iron deficiency anemia, dystrophy of nails (koilonychia) (**Fig. 37-5**) and glossitis.

Clinical Features

- *Age*—it is exclusively found in middle aged women.
- *Appearance*—patient of this syndrome have got characteristic asthenic appearance.
- *Dysphagia*—it occurs due to the formation of webs in esophagus.
- *Angular cheilitis*—vermillion borders of the lip are very thin and there is often angular cheilosis.
- *Symptoms*—patients complaint of ‘spasm in throat’ or food sticking in throat. There is also complaining of sore mouth and inability to retain dentures.
- *Tongue*—A smooth, red, occasionally enlarged and often sore tongue with fissuring is occurs.

- *Signs*—the width of mouth is narrowed and the oral mucosa is pale and painful. There is also dry mouth and spoon shaped nails. There are atrophic changes in mucosa of mouth, pharynx, upper esophagus and vulva.
- *Koilonychia*—this is also present in case of Plummer-Vinson syndrome.

Fig. 37-5: Koilonychia (spoon shaped nail) seen in Plummer-Vinson syndrome (Courtesy Dr Milind Chandurkar).

Diagnosis

- *Clinical diagnosis*—dysphagia, glossitis, with features of iron deficiency anemia will diagnose Plummer-Vinson syndrome.
- *Laboratory diagnosis*—same features as that of iron deficiency anemia. Biopsy will show atrophic epithelium and atrophy of lamina propria and muscles.

Management

- *Correction of anemia*—management is directed management of iron deficiency anemia
- *Esophageal dilation*—esophageal dilation is required to correct dysphagia.

Erythroblastosis Fetalis

It is type of isoimmune hemolytic anemia. It occurs due to isoimmune antibodies. It is also called as ‘*hereditary disease of new born*’ (HDN). Congenital hemolytic anemia due to Rh incompatibility results from destruction of fetal blood brought about by a reaction between maternal and fetal blood factors. The Rh factor, named after *Rhesus monkey*, was discovered by Landsteiner and Wiener in 1940 as a factor in human RBC which reacts with rabbit antiserum produced by administration of red blood cells from Rhesus monkey.

Pathogenesis

- *Inheritance*—it occurs due to inheritance. Blood factor from the father acts as a foreign antigen to mother fetus.
- *Formation of antibodies*—there is transplacental transfer of father antigen from fetus to mother. This will result in immunization of mother with formation of maternal antibodies against fetal antigens. If the father is Rh positive and the mother is Rh negative, fetus inherits Rh-positive antigens, which may act as antigen to the mother and immunize her with resultant antibody formation.
- *Destruction of fetal red blood cells*—some of these antibodies then cross into fetal circulation and cause the destruction of fetal red cells.
- *Complicating factors*—the problem is complicated by Rh antigens which are termed as C, D and E. Out of this; D antigen is the strongest and is responsible for the clinical manifestations of erythroblastosis fetalis.

Clinical Features

- *Stillborn*—some infants are stillborn.
- *Symptoms*—children having pallor, jaundice, compensatory erythropoiesis (both medullary and extra-medullary) and edema resulting in fetal hydrops.
- *Kernicterus*—it may manifest itself by apathy and poor feeding and later by mental retardation, irritability and cranial nerve palsies.

Oral Manifestations

- *Teeth*—it may manifest in teeth by the deposition of blood pigment in enamel and dentin of developing teeth giving them a *green, brown or blue hue*. It occurs in those portions of the teeth which are being laid down during the time when icterus was at its height.
- *Enamel hypoplasia*—enamel hypoplasia is also reported occurring in some cases of erythroblastosis fetalis. It usually involves incisal edges of the anterior teeth and middle portion of the deciduous cuspid and first molar crown.
- *Rh hump*—there is ring like defect called as 'Rh hump'.

Radiographic Features

- *Radiodensity*—there is presence of transverse lines of increased and decreased radiolucency, occurring at the ends of some long bones in some areas.
- *Cranial vault*—there is also increased thickness of cranial bone which includes maxilla and mandible. The bones of vault are thickened as a result of increased thickness of diploe.
- *Radiating spicule*—radiating spicule may also be present.

Diagnosis

- *Clinical diagnosis*—children having kernicterus, Rh hump and enamel hypoplasia will diagnose the case.
- *Laboratory diagnosis*—the red blood count at birth may vary from less than the 1,000,000 cells per cubic millimeter to near a normal level. The icterus index is very high and may reach a level of 100 units. The peripheral smear shows large number of immature RBCs. There is also evidence of hemolysis.

Management

- *Antenatal*—maternal sensitization is prevented by the administration of 300 mg of Rh antiglobulin after amniocentesis has been done. Management of affected fetus can be done by intensive plasmapheresis of mother during pregnancy in order to remove maternal antibodies or by intravenous transfusion of blood into the fetus to prevent fetal anemia.
- *Post natal*—in infants, exhibiting only anemia, fresh packed RBCs are given to correct anemia.
- *Splenectomy*—it results in striking and permanent improvement, both in anemia and symptoms. After splenectomy, daily penicillin V 250 mg 12 hourly is given to avoid infections.
- *Blood transfusion*—severe hemolytic crisis needs blood transfusion. Folic acid should be given 5 mg orally to support increased erythropoiesis.
- *Vaccination*—the patient should be vaccinated against pneumococci and hemophilus influenzae.

Sickle Cell Anemia

It is chronic hemolytic blood disorder characterized by abnormal hemoglobin (deoxygenated hemoglobin) which under low oxygen tension, results in sickling of cell. It is severe genetic disorders of hemoglobin synthesis. It is autosomal dominant. It was first described by Herrick in 1910.

Pathogenesis

- *Substitution of amino acid*—substitution of amino acid glutamine on position 6 present in the chain of the hemoglobin-A, by valine.
- *Formation of hemoglobin S*—this will give rise to an abnormal hemoglobin, i.e. hemoglobin S.
- *Formation of tactoids*—when Hbs are deoxygenated, it forms structures known as 'tactoids'.
- *Sickle shaped cells*—tactoids will distort the RBC membrane and produce characteristic sickle shaped cell which are destroyed by RE cells.
- *Thrombosis and infarction*—sickle cells increase blood viscosity and tend to reduce blood flow leading to thrombosis and tissue infarction.

- *Hemolysis*—in addition, these cells are phagocyte in large number by mononuclear-phagocyte system which reduce their lifespan and give rise with hemolysis.
- *Folic acid deficiency*—patients may develop severe folic acid deficiency due to increased erythropoiesis.

Types

- *Sickle cell disease*—in homozygous individuals, whole of hemoglobin-A is replaced by hemoglobin-S and this is known as 'sickle cell disease'.
- *Sickle cell trait*—heterozygous individuals, only 50% of HbA is replaced by HbS and this is known as 'sickle cell trait'.

Clinical Features

- *Sex and age*—it is common in females and mostly the clinical symptoms become evident before the age of 30 years.
- *Incubation period*—clinical manifestations begin only after several months as fetal hemoglobin protects against sickling phenomenon.
- *Precipitating factors*—include dehydration, chills and infection but sometime, the attack occurs spontaneously.
- *Symptoms*—there is fatigue, weakness and shortness of breath. Patient may complaint of severe abdominal pain, muscle and joint pain, at high temperature which may result in circulatory collapse. There is painless hematuria.
- *Sign*—pallor on palms (**Fig. 37-6**), there is enlargement of heart and murmur is found in most of the patients. There is increased susceptibility to infection. Most of persons expire before the age of 40 years. There is also presence of leg ulcer and gallstones. When associated with folate deficiency, there may be growth retardation and also delayed puberty.

Fig. 37-6: Pallor is seen on hand of patient with sickle cell anemia. To compare between pallor with normal hand, another hand is kept for the comparison (Courtesy Dr Milind Chandurkar).

- *Skull changes*—hyperplasia of marrow in first year of life expands the marrow cavity producing bossing of the skull, prominent malar bones and protuberant teeth.
- *Sickle cell crisis*—in this, sickling becomes severe after long quit spell of hemolytic latency. Hypoxia, infection, hypothermia or dehydration can precipitate the crisis. Patient experience severe pain due to ischemia. Each episode occasionally punctuated by exacerbations called as sickle cell crisis.
- *Acute chest syndrome*—pulmonary involvement is called as acute chest syndrome. This is serious complication of sickle cell crisis.
- *Infarction*—infarction can only occur in bone and spleen but, other tissues may also be involved. In infants, fingers and toes are commonly affected.
- *Thrombosis*—thrombosis of vessels in brain cause severe neurologic disorders like stroke, convulsion, coma, downiness as well as speech visual and hearing disturbances. Occlusion of smaller vessels results in headache and cranial nerve neuropathy including palsy and paresthesia.

Oral Manifestations

- *Oral mucosa*—the oral mucosa will show pallor and jaundice.
- *Teeth*—there may be delayed eruption and hypoplasia of the dentition, secondary to their general development.
- *Osteomyelitis*—patient is more prone to develop osteomyelitis. This may be due to hypovascularity of the bone marrow secondary to thrombosis.
- *Nerves*—patient may present with paresthesia of mental nerve which may be secondary to occlusion involving the nerves and blood supply.
- *Jaw bones*—mongoloid facies with high cheek bones and bimaxillary prognathism. It is due to marrow hyperplasia resulting in an increase in hard palate length and palate alveolar ridge angle.

Radiological Findings

- *Osteoporosis*—because of chronic increased erythropoietic activity and marrow hyperplasia, there is loss of trabeculation of the jaw bone resulting in a mild to severe generalized osteoporosis and appearance of large irregular marrow spaces.
- *Ground glass appearance*—the increased radiolucency of the jaws which is seen to have a ground glass appearance which is attributed to diminution of fine trabeculae as there is replacement of marrow by compensatory hyperplasia.
- *Inferior border of the mandible*—thinning of inferior border of mandible of alveolar cortex.

- *Lamina dura*—lamina dura appears more prominent than normal, particularly against the background of the increased radiolucency of the bone.
- *Step ladder effect*—the trabeculae in between the roots of teeth may appear as horizontal rows creating 'step ladder' like effect.
- *Maxilla and teeth*—enlargement of maxillae with protrusion and separation of upper anterior teeth.
- *Hair on end appearance*—skull radiographs show an unusual appearance, with perpendicular trabeculation radiating outward from the inner table producing a 'hair on end' pattern. There is thickening of the frontal and parietal bones. The outer table of bone may appear to be absent and diploes are thickened.

Diagnosis

- *Clinical diagnosis*—severe abdominal pain, mongoloid facies with prominent cheek bone and bimaxillary prognathism.
- *Radiological diagnosis*—hair on end appearance, step ladder effect and osteoporosis of jaw bone will diagnose sickle cell anemia.
- *Laboratory diagnosis*—a smear of peripheral blood usually shows typical sickle shaped red blood cells and hemoglobin level is decreased. The RBC count may reach level of 10 lac cells or less per cu mm with Hb levels from 5 to 12 gm/dl. The sickle hemoglobin molecule undergoes gelation or crystallization, when deoxygenated and this typically distorts the erythrocyte, producing the sickle shape. This sickle shaped cells then 'logjam' and produce stasis within the microvasculature. Damage to erythrocyte membrane also occurs in sickle cells and leads to their fragmentation and intravascular hemolysis.

Management

- *Prevention*—prevention of episode by avoiding the precipitating factors is an important aspect of treatment. Patients should avoid becoming chilled, dehydrated or exposed to hypoxia (high altitude).
- *Folic acid*—regular folic acid supplement (5 mg/daily) is given to support the greatly increased erythropoietin.
- *Antibiotics*—prophylactic antibiotics are given to prevent infections. Young patient with hyposplenism should be given phenoxymethyl penicillin.
- *Analgesics*—pain caused by tissue infarction is extremely severe but analgesics should be avoided or if at all necessary, no addictive analgesics like aspirin, paracetamol should be given because the episodes are recurrent.
- *Hydroxyurea*—this is indicated in adult patients in severe cases. The drug increases fetal form of hemoglobin which inhibits the polymerization of hemoglobin S and reduce

adherence of erythrocytes to vessels walls. It has got potential side effect and should be used cautiously.

- *Blood transfusion*—blood transfusion should be given during crisis only. Routinely, it should be avoided, because it increases the viscosity of blood.
- *Genetic counseling*—it should be done for patient who has sickle cell trait.

Dental Considerations

- *Shorten time for dental procedure*—do not prolong or carry out extensive dental procedures involving the soft tissues unless absolutely necessary. Keep the dentition as healthy as possible because there are always chances that any infection might precipitate an aplastic crisis.
- *Anesthesia*—avoid using general anesthesia or when used, it is imperative to avoid episodes of hypoxia because of the cerebral or myocardial thrombosis which might result.

Thalassemia

It is also called as 'Cooley's anemia', 'Mediterranean anemia' and 'erythroblastic anemia'. As majority of the cases of thalassemia are seen in the region of Mediterranean Sea, the name thalassemia is given, thalassa stands for sea. It is autosomal dominant.

It is an inherited impairment of hemoglobin synthesis in which there is partial or complete failure to synthesize a specific type of globin chain. Beta thalassemia is more commonly occur as compared to alpha thalassemia.

Pathogenesis

- *Absence of alpha or beta chains*—hemoglobin molecule composed of two alpha and two beta chains. Either alpha or beta globulin genes may be affected.
- *Reduces hemoglobin*—if one of chains is not made adequately, the resultant red blood cells have reduced hemoglobin. This will result in shortened lifespan of RBCs.
- *Alteration in structure of cells*—the excess globin chains accumulate within the erythrocytes, which results in alteration in structure of cells.
- *Hemolysis*—these abnormal erythrocytes got destructed in spleen (hemolysis) and patient suffers from hypochromic and microcytic anemia.
- *Bone marrow hyperplasia*—this occur as rare of hematopoiesis is increased to maintain adequate oxygenation.

Types

- *Alpha thalassemia*—there is reduction or absence of α chain synthesis. Alpha chains of hemoglobin are required not only for HbA but also for HbF, which is the

main hemoglobin type in fetal life. Therefore, major type of alpha thalassemia is incompatible with life and results in hydrops fetalis and intrauterine death of fetus.

- *Beta thalassemia*—there is reduction or absence of beta chains. Hemolysis is not primarily due to lack of β -globin chains but it is because of the free alpha chains which form insoluble aggregates that precipitate within the RBCs and cause damage to the cell membranes.
- *Thalassemia major or homozygous β -thalassemia*—occurs when the patient is homozygous. It is also called as Cooley's anemia. In this case two defective gene is affected.
 - *Hemoglobin H disease*—it is very mild form of the disease in which the patient may live relatively normal life.
 - *Hemoglobin Bart disease*—in which infants are stillborn or die shortly after birth.
- *Thalassemia intermedia*—it is group of disorders characterized by clinical manifestations between major and minor.
- *Thalassemia minor or thalassemia trait*—occurs when the patient heterozygous. In this, only one defective gene is affected.

Clinical Features

- *Age*—occurs between the ages of 6 to 24 month and after the age of 6-8 months.
- *Symptoms*—the patient first presents with pallor of skin, fever, chills, malaise, generalized weakness, prominent cheek bone and mild hepatosplenomegaly.
- *Mongoloid appearance*—bone marrow hyperplasia in early life may produce frontal head bossing and there may be marked overdevelopment of malar bone which is associated with a short nose having a depressed bridge giving the appearance of mongoloid.
- *Organs failure*—deposition of iron in various organs (due to multiple transfusions) leads to signs and symptoms of organ failure.
- *Prognosis*—most patients die in childhood due to anemia and cardiac failure.
- *Alpha thalassemia*—the clinical findings are severe alveolar bone loss, pronounced spacing of maxillary anterior teeth and mongoloid appearance.

Oral Manifestations

- *Jaw bone*—there is excessive overgrowth of maxilla causing excessive lacrimation and nasal stuffiness.
- *Oral mucosa*—the oral mucosa is pale and has a lemon yellow tint because of chronic jaundice. The color is best seen at the termination of hard palate and in the floor of mouth.

- *Rodent facies*—there is marked over development of maxilla associated with hyperplasia of alveolar process, which results in anterior open bite and prominent cheek bone producing characteristic 'rodent facies'.
- *Chipmunk facies*—there is also saddle nose, prominent malar bone and pneumatization of maxillary sinus. As a result of these skeletal changes, the upper lip is retracted giving the child a 'chip munk' facies.
- *Teeth*—the maxillary teeth are protrudes with spacing between them with a short upper lip due to a lag between the growth of the maxilla and the growth of upper lip. Due to high concentration of iron, discoloration of dentin and enamel may be evident.
- *Poor healing*—there is poor healing after dental treatment.

Radiographic Features

- *Teeth*—the root of mandibular 1st molar and central incisors may be spike shaped and short. The lamina dura is thin and the roots of the teeth may be short. Circular radiolucency may be seen in the lower anterior region. There is thinning of the crypt of developing teeth.
- *Alveolar bone*—the alveolar bone shows large bone marrow spaces, osteoporosis and blurring of trabeculae. The marrow spaces are large and the trabeculae are large and course.
- *Compensatory lamellar striation*—some areas may show prominent trabeculae which have been referred to as 'compensatory lamellar striation'.
- *Long bones*—in the long bone there is generalized radiolucency, increased width of shaft, and narrowing of cortices due to the greater amount of marrow substance. There is also pathological fracture.
- *Skull*—skull is thickened as a result of increased width of the dipole space between the outer and inner tables of the vault. This occurs due to proliferation of the hemopoietic tissue. Generalized granular appearance in skull.
- *Antrum*—the antra is reduced in size by the encroachment of the bone formation, which is sometimes sufficient to cause complete effacement of the air sinuses.
- *Premaxilla*—premaxilla is prominent resulting in malocclusion.
- *Cortical borders*—there is generalized thinning of cortical borders.
- *Hair on end appearance*—the trabeculae joining the inner and outer table of the skull are readily arranged calcified spicules which appear as calcified hair extending between the inner and outer tables, which is called as 'hair on end' appearance (Fig. 37-7).

Diagnosis

- *Clinical diagnosis*—mongoloid appearance, chipmunk facies, and rodent facies with discoloration of dentin may give clue to diagnosis of thalassemia.

Fig. 37-7: Typical hair on end appearance seen in thalassemia patient (Courtesy Dr Ganju).

- **Radiological diagnosis**—hair on end appearance, compensatory lamellar striation with spike shaped mandibular molar.
- **Laboratory diagnosis**—the anemia is hypochromic and microcytic. The peripheral smear shows abnormal RBCs. Reticulocyte count is increased. Bone marrow shows increased erythropoietic activity. Serum bilirubin and fecal and urinary urobilinogen are elevated because of severe hemolysis. An elevated fetal hemoglobin is present. Biopsy shows typical safetypin cells in the circulation.

Management

- **Blood transfusion**—repeated blood transfusions are necessary. Repeated blood transfusion will lead to increased iron load in the tissue of the body. This will lead to a condition known as *hemochromatosis*.
- **Chelating agent**—iron overload can be reduced by regular use of chelating agents like *desferrioxamine* therapy.
- **Bone marrow transplantation**—allogenic bone marrow transplantation can be done. It is indicated in young individual, little organ damage and HLA matched donor.
- **Splenectomy**—splenectomy is indicated when there is an increase in the severity of anemia.
- **Folic acid**—the patient may need supplementary folic acid because of increased requirement owing to increased erythropoiesis.
- **Surgical correction**—it is indicated in patient who developed an abnormal facial appearance.

Erythropoietic Porphyria

It is a group of inherited or acquired disorders characterized by excessive production, accumulation and excretion of

porphyrins and their precursors. It is a metabolic defect within the maturing erythrocytes resulting in excessive production of uroporphyrinogen-I.

Clinical Features

- **Age**—it occurs soon after birth.
- **Symptoms**—the urine is burgundy red in color or turns red on exposure to light.
- **Signs**—photosensitivity of exposed parts of body leads to formation of blister and scars.
- **Anemia**—there is also hemolytic anemia and splenomegaly.

Oral Manifestations

- **Erythrodontia**—there is deposition of porphyrin in dentin, to a lesser extent in the enamel which imparts red or brown color to deciduous and permanent teeth (erythrodontia). The staining by uroporphyrin can be confirmed by ultraviolet light which will produce fluorescence.
- **Signs**—bullous erosions of oral mucosa can be seen. In advanced cases, pigmented atrophic scars on lip are seen resemble the keloid structures. The patient is hence, unable to close his mouth.

Diagnosis

- **Clinical diagnosis**—burgundy red color urine which turns red upon exposure to light with erythrodontia will diagnose the disease.
- **Laboratory diagnosis**—about 50% normoblasts, reticulocyte and 50% RBCs exhibit intense red fluorescence under fluorescence microscope.

Management

- **Splenectomy**—in severe cases of hemolysis, splenectomy may be carried out.

Megaloblastic Anemia

Megaloblastic anemia occurs due to deficiency of vitamin B₁₂ or folate or both, resulting in disordered cell proliferation leading to megaloblastic anemia. All megaloblastic anemias have erythroid precursors known as megaloblasts.

Causes

- **Folate deficiency**—the condition is prevalent in women during pregnancy and lactation. It may occur due to low availability of folate in diets, prolonged cooking of food, malabsorption syndromes such as tropical sprue and malaria.

- **Vitamin B₁₂ deficiency**—removal of vitamin B₁₂ from the gut either by bacterial proliferation or by parasites. It may occur due to chronic dietary deficiency of the vitamin.

Clinical Features

- **Symptoms**—there are symptoms of anemia like weakness, loss of appetite and palpitations. Patient may get periodic diarrhea.
- **Skin**—in severe cases, skin may show faint lemon yellow tint and spleen may be palpable.
- **Neuropathy**—many cases show paresthesia of finger and toes and dementia may also be seen.

Oral Manifestations

- **Symptoms**—burning sensation in tongue, hypersensitivity, paresthesia and later dryness of the mouth.
- **Hunter's glossitis**—atrophy of filiform and fungiform papillae leads to completely atrophic smooth fiery red surface of tongue (Hunter's glossitis) (**Fig. 37-8**).
- **Angular cheilitis**—angular cheilitis and dysphagia due to pharyngitis and esophagitis.
- **Oral mucosa**—yellowish brown pigmentation of oral mucosa may occur due to increased circulating bile pigments.

Fig. 37-8: Hunter glossitis showing fiery red appearance in megaloblastic anemia.

Diagnosis

- **Clinical diagnosis**—symptoms of anemia with Hunter glossitis with dysphagia may give clue to diagnosis.
- **Laboratory diagnosis**—the peripheral smear shows a macrocytic blood picture with many abnormal forms of RBCs. There is associated leukopenia and sometimes, thrombocytopenia. Bone marrow shows presence of megaloblasts and erythroid hyperplasia. In advanced

cases, the red blood cell abnormalities are detected like polychromatophilic cells, stippled cells, nucleated cells, Howell-Jolly bodies and Cabot's ring.

- **Bone marrow finding**—there is increased number of immature red cells or megaloblasts with a few normoblast. Polymacocytes or large PMNs with large polylabeled nuclei are found. Megakaryocytes appear normal.

Management

- **Education**—general education on cooking practices and food habits is undertaken in tropical countries to prevent nutritional anemia.
- **Blood transfusion**—when hemoglobin level is less than 4 gm/dl blood, transfusion should be given.
- **Vitamin B₁₂**—oral administration of vitamin B₁₂ should be given.
- **Folic acid**—folic acid supplements should also be given.

Pernicious Anemia

It is also called as 'primary anemia', 'Addison's anemia' or 'Biermer's anemia'. The term pernicious anemia should be reserved for patients who have B₁₂ deficiency secondary to intrinsic factor deficiency.

Causes

- **Atrophy of gastric mucosa**—it occurs due to atrophy of gastric mucosa resulting in failure to secrete the still unidentified 'intrinsic factor'.
- **Autoimmune disorders**—it is suggested that it is autoimmune disorder, because autoantibodies to gastric parietal cells are often found in patients.

Clinical Features

- **Age**—it is rare before the age of 30 years and increase in frequency with advancing age. Males are more commonly affected than females.
- **Symptoms**—there is usually triad of symptom: generalized weakness, sore painful tongue, numbness and tingling of the extremities. Other features are fatigability, headache, dizziness, nausea, vomiting, diarrhea, loss of appetite, shortness of breath, loss of weight, pallor and abdominal pain.
- **Nervous system**—nervous system disorders are also present and manifested by sensory disturbances including the paresthetic sensation of the extremities, weakness, stiffness and difficulty in walking, general irritability, depression, drowsiness as well as incoordination on loss of vibratory sensation. There is also tingling sensation in the fingers and toes that eventually progress to numbness.
- **Gastrointestinal complaint**—Epigastric discomfort, constipation or diarrhea can be seen in these patients.

Oral Manifestations

- **Symptoms**—glossitis (**Fig. 37-9**) and patient complains of painful and burning lingual sensation which may be so annoying that the dentist is often consulted first. Sometimes, inflammation and burning involve the entire oral mucosa. There is disturbance in taste sensation with intolerance to dentures and occasional dryness of mouth.

Fig. 37-9: Glossitis in patient with pernicious anemia.

- **Beefy red tongue**—the tongue is generally inflamed often described as 'beefy red' in color, either entirely or in patches scattered over the dorsum and lateral border of tongue.
- **Hunter glossitis or Moeller glossitis**—there is gradual atrophy of the papillae of tongue that eventuates in a smooth and bald tongue which is often referred as *Hunter's glossitis* or *Moeller's glossitis* and is similar to the 'bald tongue of sandwich' seen in pellagra. The fiery red appearance of tongue may undergo remission but recurrent attacks are common.
- **Xerostomia**—patient may notice xerostomia. Xerostomia may lead to occurrence of lobulation on tongue.
- **Oral mucosa**—oral mucosa shows greenish yellow color (frequently observed on the skin) at the junction of hard and soft palate, when daylight is used for illumination.

Diagnosis

- **Clinical diagnosis**—triad of generalized weakness, sore and painful tongue and numbness and tingling of extremities are typical of pernicious anemia. Patient also suffers from gastrointestinal problems.
- **Laboratory diagnosis**—histologically, oral epithelial cells in pernicious anemia reveal enlarged, hyperchromatic nuclei with prominent nucleoli and serrated nuclear membranes. The red blood count is decreased often to 3

or less per cubic millimeter. Cells exhibit macrocytosis, poikilocytosis. There is also decreased WBC count and mean corpuscular hemoglobin. In advanced cases of anemia, there are polychromatophilic cells, stippled cells, nucleated cells, Howell-Jolly bodies and Cabot rings. Bone marrow shows great number of immature red cells or megaloblasts with few normoblasts (**Fig. 37-10**), indicating maturation arrest at the more primitive megaloblast state.

- **Gastric pH**—achlorhydria or lack of gastric hydrochloric acid secretion is a constant feature and pH of the gastric content is usually high. Achlorhydria is associated with atrophy of the gastric mucosa, which commonly occurs in presence of chronic inflammation.
- **Schilling test**—Schilling test detects the absence of intrinsic factor. This is discussed in detail in *Chapter 18: Investigations in Dentistry*.

Fig. 37-10: Megaloblasts seen on peripheral smear in patient with pernicious anemia.

Management

- **Vitamin B₁₂**—most of the patients should be given vitamin B₁₂ parenterally but, some of the patients are treated with massive oral dose of vitamin B₁₂. The standard dosage is 100 mg IM every 30 days.

Aplastic Anemia

It is a rare disorder characterized by peripheral blood pancytopenia (anemia, leukopenia and thrombocytopenia) associated with bone marrow suppression. It occurs due to failure of hematopoietic precursor cells in bone marrow to produce adequate number of all types of blood cells. In

most cases, the cause of bone marrow suppression is not known and hence is known as idiopathic aplastic anemia. Aplastic anemia can be associated with Fanconi anemia and dyskeratosis congenita.

Types

- *Primary or idiopathic aplastic anemia*—it is the disease of unknown origin which occurs most frequently in young adults, develops more rapidly and usually terminates fatally.
- *Secondary*—it has known etiology occurs at any age and presents better prognosis.

Etiology

- *Drugs and chemicals*—common drugs which can cause aplastic anemia are benzene derivatives, chloramphenicol, amidopyrine, organic arsenicals, colloidal silver, bismuth, mercury, sulfonamides, penicillin and anticancer drugs. The mechanism due to which drug can cause aplastic anemia is as follows:
 - *Myelosuppressive effect*—the first is characterized by the myelosuppressive effects of cancer chemotherapeutic agents.
 - *Marrow depression*—some drugs can cause marrow depression.
 - *Hypersensitivity reaction*—the third type is called as idiosyncratic or hypersensitivity induced aplastic anemia.
- *Infections*—patient with bacterial disease such as tuberculosis and viral infections like hepatitis and infectious mononucleosis can cause aplastic anemia.
- *Radiation*—long term continuous exposure to small amounts of external radiation may lead to aplastic anemia.
- *Other causes*—in some cases, pregnancy and thymoma can also cause aplastic anemia.

Clinical Features

- *Age*—it can occur at any age, but is common in young adults.
- *Symptoms due to erythrocyte deficiency*—patient may feel weakness after slight physical exertion and exhibits pallor of skin. There is also breathlessness, headache.
- *Symptoms due to platelet deficiency*—there is marked tendency to bruising and bleeding. Patient may get retinal and cerebral hemorrhages.
- *Deficiency of white blood cells*—bacterial and fungal infection are common occurrence due to white blood cell deficiency.
- *Others feature*—patient may get ankle edema, numbness and tingling of extremities, anginal pain, and congestive cardiac failure.

Oral Manifestations

- *Oral mucosa*—the mucosa shows pallor due to decreased number of red blood cells.
- *Symptoms*—in some cases, spontaneous hemorrhage from gingiva is present.
- *Sign*—petechiae, often are present on the soft palate and in severe cases, there may be submucosal ecchymosis. Large ragged ulcers covered by gray or black necrotic membrane may be present, which are the result of generalized lack of resistance to infection and trauma.
- *Gingival hyperplasia*—in some cases, gingival hyperplasia may occur in aplastic anemia (Fig. 37-11).

Fig. 37-11: Gingival hyperplasia associated with aplastic anemia (Courtesy Dr Milind Chandurkar).

Diagnosis

- *Clinical diagnosis*—clinical features suggesting of thrombocytopenia (bleeding), WBC deficiency (infection) and erythrocyte deficiency (pallor) will give clue to the diagnosis.
- *Laboratory diagnosis*—RBC count is remarkably diminished, as low as 1 million cells/mm³. WBC count is as low as 2000/mm³ and platelet count may fall below 20000/mm³. The classical finding is that of pancytopenia along with reduction of absolute reticulocyte count. Bleeding time is prolonged and clotting time is normal. Anemia is normocytic with some degree of macrocytosis. Bone marrow is fatty and few developing cells.

Management

- *Removal of cause*—withdrawal of the etiological agent.
- *Supportive therapy*—it is in the form of antibiotics and transfusion.
- *Hemopoiesis*—stimulation of hemopoiesis by androgenic steroid.
- *Bone marrow transplantation*—it can be useful in some cases.

- *Anti-fibrinolytic agents*—gingival bleeding can be reduced by using systemic anti-fibrinolytic agents such as aminocaproic acid or transexamic acid and local treatment.
- *Immunosuppressive therapy*—it is recommended in patients who are not able to take bone marrow transplantation. Antithymocyte globulin combine with cyclosporine will produce good results.

Fanconi's Anemia

It is a rare congenital disease characterized by pancytopenia, bone marrow hypoplasia and congenital anomalies.

Clinical Features

- *Age*—it is usually seen in children.
- *Skin*—there is brown pigmentation of skin.
- *Hypoplasia*—there is, also, hypoplasia of kidney and spleen.
- *Symptoms*—patient suffers from microcephaly, hypoplastic thumb, and short stature, polydactyly and squint.
- *Other features*—there may be mental and sexual retardation.

Oral Manifestations

- *Gingival bleeding*—there is gingival bleeding which may occur spontaneously.
- *Infection*—frequent infections of oral cavity can occur.

Diagnosis

- *Clinical diagnosis*—pancytopenia with congenital anomalies will diagnose this condition.
- *Laboratory diagnosis*—it is same as that of aplastic anemia.

Management

- *Anti-thrombolytic agents*—gingival bleeding can be reduced by anti-thrombolytic agents such as aminocaproic acid and transexemic acid 20 mg/kg QID 24 hrs before procedure and continued for 3 to 4 days.

Uncommon Causes of Anemia

- *Autoimmune hemolytic anemia*—in this disorder, hemolytic anemia is caused by the presence of antibodies reactive against normal or altered red cell membrane. Antibodies present can be *warm antibody* (IgG antibodies which are active at 37° Celsius) and *cold antibody type* (IgM antibodies below 30° Celsius leading to hemolysis of RBCs).
- *Anemia due to drugs*—number of drugs like naphthalene, nitrofurantoin, amino salicylic acid, phenacetin, dapsone, sulfones and nitrobenzene may cause anemia.

Anemia develops within 1 to 2 weeks after the drug therapy is started and show abnormalities like reticulocytosis, erythrocyte abnormalities, hyperbilirubinemia, and erythroid hyperplasia of the bone marrow.

- *Anemia due to chemicals*—chemicals which can cause anemia are arsenic, potassium chlorate and pyrogallol acid.
- *Anemia due to physical agents*—acute hemolytic anemia has been observed in extensive thermal burns due to direct effect of heat on RBCs, severity of which is related to the area of the body surface affected. Anemia may last for many weeks.
- *Pyruvate kinase deficiency anemia*—when there is pyruvate kinase deficiency during glycolysis in the RBC, there is discrepancy between the ATP generating capacity of RBC and energy needed, leading to loss of pliability which result in distorted and rigid cells which are ultimately destroyed by the spleen. Anemia of varying degrees, jaundice and splenomegaly or pronounced neonatal jaundice are common findings. Anemia is normocytic and normochromic with reticulocytosis.
- *Glucose 6 phosphatase deficiency anemias*—glucose-6-Phosphatase is required to maintain glutathione in the reduced state which protects the RBCs from metha-hemoglobin formation. In normal state there is no anemia but acute hemolysis is characterized by jaundice, pallor and dark urine with or without abdominal and back pain. It remains asymptomatic unless RBCs are subjected to injury by exposure to certain drugs like anti-malarial, vitamin K, aspirin and certain infections like Salmonella, *E. coli*, etc. Peripheral smear shows abnormal forms of RBC and reticulocytosis. There is also increase in WBC count.
- *Hereditary spherocytosis*—in this, there is abnormalities in shape of RBC. In this disorder, red blood cells are excessively permeable to sodium ion. The osmotic fragility of red cells is abnormal in these conditions. It will lead to loss of cell membrane and gradually the cell becomes spherical in shape and is destroyed by spleen, giving rise to hemolytic anemia. Patient will get mild to moderate hepatosplenomegaly, jaundice and anemia. Radiologically, radiating spicule may be present, but they are less widely distributed, although symmetrically situated on two sides of the affected region. The peripheral smear shows presence of spherocytes.
- *Hereditary elliptocytosis*—it is a genetically determined abnormality of the red cell shape associated with variable degree of hemolysis. Most of the patients have no clinical manifestations but few may show signs of chronic hemolytic anemia. The peripheral smear shows larger number of elliptocytes. Mild anemia of normocytic, normochromic type is also present.

- *Paroxysmal nocturnal hemoglobinuria*—it is a very rare disease in which the red cells have acquired susceptibility to antibodies which are normally in the blood. The patient has severe to moderate anemia and mild jaundice. The spleen is usually palpable. There is passage of dark urine usually in morning sample with subsequent samples of urine being clear. There are findings of hemolytic anemia in association with reticulocytosis. There may be leukopenia and thrombocytopenia. Administration of alkali may control hemolysis but on cessation of treatment, massive hemolysis may occur due to accumulation of sensitive cells during the period of therapy.

Dental Considerations of Anemia

- *Blood investigations*—routine blood investigation should be carried out in patient whom you suspecting anemia.
- *Physician referral*—if hemoglobin is significantly less, patient is referred to physician for further diagnosis and treatment.
- *Surgical procedure*—don't perform any surgical and periodontal procedures on patients with marked anemia. Never give general anesthesia unless Hb is at least 10 g/dl.
- *Maintenance of oral hygiene*—oral rinse with chlorhexidine 0.2% in aqueous solution will reduce the amount of plaque and number of microorganisms.
- *Injection*—intramuscular injection and nerve block anesthesia should be avoided because of thrombocytopenia and bleeding tendency.

Polycythemia

It is defined as abnormal increase in the number of red blood cells in the peripheral blood, usually with an increase in hemoglobin level.

Types

- Polycythemia vera
- Relative polycythemia.
- Secondary polycythemia

Polycythemia Vera

It is also called as '*polycythemia rubra vera*', '*Osler's disease*', '*Vaquez's disease*' and '*erythremia*'. There is an uncontrolled proliferation of the erythroid stem cells leading to excess of erythroid cell mass in the body (RBCs). There is accompanying increase in the granulocyte and megakaryocytic elements though to a lesser degree.

Clinical Features

- *Age and sex*—the disease is more common in males and usually occurs in middle age or later.
- *Symptoms*—common symptoms are lassitude, loss of concentration, headache, dizziness and blackout, slurring of speech, pruritis, mental confusion and indigestion. Paresthesia is common, usually involving the cranial nerves.
- *Signs*—the skin appears flushed or diffusely reddened. Spleen is palpable in most of the patients. Superficial veins are dark, enlarged and distended. The tip of the finger usually has a cyanotic appearance.
- *Appearance*—there is marked purplish red discoloration especially of the head and neck (**Fig. 37-12**). Feet and hands, which give the patient an extremely angry appearance.
- *Erythromelalgia*—it is peripheral vascular event occur on hands and feet. There is burning sensation with erythema and warmth in hand and feet. This may lead to thrombotic occlusion of vessels supplying digits which may results in digital gangrene and necrosis.
- *Complications*—thrombotic complications may occur and peptic ulcerations are common.

Fig. 37-12: Purplish red discoloration seen in eyes in patient with polycythemia (Courtesy Dr Millind Chandurkar).

Oral Manifestations

- *Appearance*—there is purplish red discoloration of the ears, oral mucosa, gingiva and tongue.
- *Tongue*—the tongue may appear as if it has been painted with crystal violet.
- *Gingiva*—the gingiva is markedly swollen and bleeds spontaneously, but with no tendency to ulcerations.
- *Oral mucosa*—petechiae of the oral mucosa are common.
- *Hemorrhage*—in such patients, severe hemorrhage may follow surgical procedures.

Diagnosis

- *Clinical diagnosis*—purplish red discoloration of skin with Erythromelalgia accompanied by gingival hemorrhage is typical clue of this disease.
- *Laboratory diagnosis*—the hemoglobin level is greater than 18 gm/dl with an associated elevation of WBC and platelet count. The bone marrow is hypercellular with erythroid hyperplasia, increased number of megakaryocytes and granulocytes.

Management

- *Venesection*—Venesection done at periodic intervals to remove 500-600 ml of blood is the simplest therapeutic measure. It is also called as phlebotomy.
- *Radioactive phosphorus*—radioactive phosphorus may be used when the Diagnosis is certain. It is an excellent treatment modality.
- *Aspirin*—it is given for the thrombotic event.
- *TEM*—oral administration of 30 mg tri-ethylene-melamine (TEM) with remission of 8 to 9 months.
- *Chemotherapy*—chemotherapy with busulfan 2-4 mg/day or melphalan orally to bring down the cell count.

Relative Polycythemia

It is also known as '*stress or spurious (false) polycythemia*' and is due to reduction in the plasma volume.

It is an apparent increase in the number of circulating red blood cells that occurs as a result of loss of blood fluid with hemoconcentration of cells and is seen in cases of excessive loss of body fluids such as chronic vomiting, diarrhea or loss of electrolytes with accompanying loss of water. The red cell mass is normal.

Secondary Polycythemia

This occurs as a result of hypoxia, which stimulates the production of erythropoietin, e.g. at high altitudes, pulmonary diseases or congenital heart diseases.

Secondary polycythemia may also occur in some brain tumors, usually vascular, Cushing's syndrome and renal and lung carcinoma.

White Blood Cell Disorders

For classification of white blood cell disorders (see Table 37-4).

Quantitative Disorders

Agranulocytopenia or Neutropenia

It is also called as '*granulocytopenia*', '*agranulocytic angina*'. It is a serious disease characterized by marked leukopenia

Table 37-4: Classification of white blood cell disorders

Quantitative disorders

Decrease in number

- Granulocytopenia/leukopenia/agranulocytopenia
- Neutropenia
 - Cyclic neutropenia
 - Primary splenic neutropenia
 - Chronic hypoplastic neutropenia
 - Chronic granulocytopenia in childhood
 - Familial neutropenia
 - Transitory neonatal neutropenia

Increase in number

- Granulocytosis
- Neutrophilia
- Basophilic leukocytosis
- Eosinophilic leukocytosis
- Lymphocytosis
- Monocytosis

Qualitative disorders

- Lazy leukocyte syndrome
- Chédiak-Higashi syndrome
- Multiple myeloma
- Infectious mononucleosis
- Lymphoma
- Leukemia

with reduction and absence of neutrophilic leukocytes. Neutropenia is decreases in number of neutrophils and Agranulocytopenia is absent of neutrophils.

Types

- *Primary agranulocytosis*—in this, etiology is unknown.
- *Secondary agranulocytosis*—in it, cause is recognized.
- *Mild neutropenia*—when 1000/mm³ to 2000/mm³ neutrophils are present.
- *Moderate neutropenia*—when 500/mm³ to 1000/mm³ neutrophils are present.
- *Severe neutropenia*—when fewer than 500/mm³ neutrophils are present.
- *Agranulocytosis*—when no neutrophils are seen in peripheral smear.

Etiology

- *Idiosyncrasy*—idiosyncrasy or sensitization to certain drugs like aminophylline, chlorpromazine and phenylbutazone, benzene, bismuth, chloramphenicol, sulfonamides and use of cytotoxic drugs or anti-metabolics.
- *Deficiency*—deficiency of vitamin B₁₂ and folic acid.
- *Infections*—certain infections decrease the number of neutrophils in circulating blood because of increased migration of neutrophils into the tissue, destruction of neutrophils or direct effect of microorganism and its toxins on the bone marrow. Infection with hepatitis A

and varicella zoster virus infection are commonly associated with neutropenia. Overwhelming bacterial infection, particularly septicemia can be accomplished by neutropenia because cells are used at rapid rate to overcome infection.

- *Diseases*—disease causing sequestration of neutrophils includes systemic lupus erythematosus and Felty's syndrome. It can be associated with leukemia, pancytopenia and hypersplenism.
- *Hemodialysis*—hemodialysis patient experience decrease in neutrophils owing destruction by complement activated by the dialysis membrane.
- *Irradiation*—excessive irradiation can cause neutropenia due to direct toxic effect on division of bone marrow cells.

Clinical Features

- *Age and sex*—it can occur at any age but is somewhat more common in adults, particularly in woman.
- *Occupation*—it is also common in professional and in hospital as they have easy access of the offending drugs and often use drug sample injudiciously.
- *Symptoms*—the onset may be sudden or gradual. The condition begins with sore throat, high fever and often rigors, which may be followed by prostration.
- *Skin*—the skin appears pale and anemic and in some cases, jaundiced.
- *Signs*—there is rapidly advancing necrotic ulceration of throat and mouth with little evidence of pus formation. In case of Agranulocytopenia patient dies within 3-5 days due to toxemia and septicemia.

Oral Manifestation

- *Sites*—the most common sites are gingiva (**Fig. 37-13**), palate, tonsil and pharynx.

Fig. 37-13: Patient having severe gingivitis with neutropenia.

- *Symptoms*—There may be associated pain, excessive salivation and spontaneous oral hemorrhage.
- *Appearance*—the oral lesions appear as necrotizing ulcerations of oral mucosa, tonsils or /and pharynx.
- *Surface of the lesion*—the lesions appear as ragged and necrotic and are covered with a gray black membrane. The necrotic tissue is often with foul smelling.
- *Margins of lesion*—there is lack of inflammation at the margin of lesions.
- *Supporting structures*—the disease spreads quickly in gingival tissues causing destruction of supporting structures and inevitable loss of deciduous and permanent teeth.

Radiological Findings

- *Destruction of alveolar bone*—supporting alveolar bone is rapidly destroyed, so that teeth are denuded of bone and are supported only by soft tissues.
- *Osteomyelitis*—very rarely, infection spreads to deep into the marrow to cause osteomyelitis.

Diagnosis

- *Clinical diagnosis*—gingival ulceration, infection and anemic patient may give clue to the diagnosis
- *Laboratory diagnosis*—majority of patients show a leukocyte count below 2000 cells per cu mm and granulocyte count below 100 cells per cu mm. Hemoglobin and platelet counts are normal.

Differential Diagnosis

- *Leukemia*—anemia, purpura and WBC leukocyte above 1000,000/mm³ with prolonged bleeding and clotting time.
- *Cyclic neutropenia*—marked cyclic appearance every 20 to 25 days.
- *Wegener's granulomatous*—kidney and lung involvement.
- *ANUG*—necrosis starts on papilla tips, not necessary associated with leukopenia.
- *Necrotizing sialometaplasia*—large ulcerations with induration on hard and soft palate, flat border and painless. General condition is not affected.
- *Erythema multiforme*—target lesions and no specific blood picture.

Management

- *Removal of causative agent*—the most important measure is removal of the offending agent if it can be identified.
- *Transfusion*—if hemoglobin is less than 10 gm/dl, transfusion of red cell concentrate is given. In some cases, white cell transfusion can be given.

- **Antibiotics**—septicemia can be controlled by parenteral antibiotic therapy along with corticosteroid therapy. A combination of carbenicillin, methicillin and gentamicin is commonly used because of broad coverage against most organisms.
- **Granulocyte macrophage colony stimulating factors (GM-CSF)**—this is given if agranulocytosis is related to cancer treatment.
- **Oral and dental management**—antibacterial mouth rinse may be helpful for ulcers. The soft splint which covers entire maxillary area and carries a medication is used in palatal ulcers. The pain of oral ulcer is reduced by use of topical anesthetic mouth rinses. A solution containing 5% dyclonine and 5% diphenylhydramine hydrochloride (benydryl) mixed with magnesium hydroxide (milk of magnesia) or kaolin with pectin is useful for this purpose. Use of splint to cover the palatal lesion and carries medication in a well that continually bathes the oral ulcers.

Cyclic Neutropenia

It is also called as '*periodic neutropenia*' or '*cyclic hematopoiesis*'. It is a rare disorder characterized by periodic or cyclic diminution in circulating neutrophils due to failure of stem cells of bone marrow. It is also called as periodic neutropenia. One-third cases are inherited as autosomal dominant trait and 2/3rd appear spontaneously during the first few year of life. The patient is healthy between neutropenic periods; but at regular intervals, the absolute neutrophils count falls below $500/\text{mm}^3$. In some patients, it comes to zero.

Clinical Features

- **Age and sex**—the disease is frequently present during infancy and childhood and both sexes appear to be equally affected.
- **Occurrence**—the frequency of neutropenic episodes vary from once in 2 to 4 weeks which last for 3 to 5 days with 21 days gap being the commonest.
- **Symptoms**—the patients manifest fever, sore throat, stomatitis and regional lymphadenopathy as well as headache, arthritis, cutaneous infection and conjunctivitis. Less frequently patient experience lung, urinary tract infection as well as rectal and vaginal ulcer.
- **Amyloidosis**—in some patients, amyloidosis can occur due to repeated, increased antigenic stimulation during neutropenic episodes.

Oral Manifestations

- **Site**—lesions are found on the lip, tongue, palate, gums and buccal mucosa.

- **Gingivitis**—severe gingivitis is present on gingiva.
- **Ulceration**—painful ragged ulcers that have a core like center are present. It heals after about two weeks with scarring. Isolated painful ulcer may occur which correspond to the period of neutropenia.

Radiological Features

- **Bone loss**—it exhibits mild or severe loss of superficial alveolar bone advancing to periodontitis.
- **Prepubertal periodontitis**—in children this loss of bone around multiple teeth sometimes called as '*prepubertal periodontitis*'.

Diagnosis

- **Clinical diagnosis**—recurrent gingival ulceration, recurrent infection with prepubertal periodontitis may yield in diagnosis.
- **Laboratory diagnosis**—neutrophils count should be less than $500/\text{mm}^3$ during each of three successive cycles. There is increased in monocytes and lymphocytes count. At the peak of the disease, the neutrophils may completely disappear for one or two days.

Management

- **Antibiotic therapy**—this can be given to control the infection in the patient.
- **Corticosteroid therapy and hormonal therapy**—in some cases, use of corticosteroids, adrenocorticotropin (ACTH) or testosterone modulates sharp reduction in marrow function.
- **Oral hygiene maintenance**—oral hygiene should be maintained and patient should be recalled for oral hygiene every 2-3 months.
- **Cytokine granulocyte colony-stimulating factor (G-CSF)**—this can be given several times weekly to correct lack of production of neutrophils. This will decrease time of neutropenia from 5 days to 1 day thereby decreasing clinical course of disease.
- **Other therapy**—other therapy like splenectomy and nutritional supplement can be carried out.

Variant of Neutropenia

- **Chronic idiopathic neutropenia**—it is an uncommon disease in which there is decreased production of neutrophils. The bone marrow shows a number of immature cells but there is a decrease in number of mature neutrophils. Most of the patients are asymptomatic because of compensatory monocytosis. In the oral cavity recurrent ulcerations of the gingival, lips, buccal mucosa and recurrent dental abscess have been reported.

- *Primary splenic neutropenia*—it is characterized by neutropenia of a mild degree, splenomegaly and myeloid hyperplasia of the bone marrow. The common clinical features are polyarthritis, recurrent oral ulceration, weight loss and fatigue.
- *Chronic granulocytopenia in children*—it is a benign disorder characterized by repeated pyogenic infection. It is due to increased destruction of neutrophils. Complete recovery takes place eventually.
- *Familial neutropenia*—it is a rare benign disorder transmitted as a non-sex linked dominant trait. Most of the patients are asymptomatic but a few may show periodontal disease and a tendency to develop frequent furuncles. The total leukocyte count is normal but there is associated neutropenia.
- *Transitory neonatal neutropenia*—it is a disorder caused by fetal-maternal incompatibility involving only the neutrophils. Skin infection is the most common clinical finding. The blood picture shows normal leukocyte count, severe neutropenia, monocytosis and mild eosinophilia. The duration of neutropenia varies from 2 to 17 days.

Increased in Number of WBC

- *Neutrophilia*—it is characterized by an increase in blood neutrophil concentration above 7.25×10^6 . It is seen in acute and chronic infection.
- *Granulocytosis*—in this, there is an increase in the granulocytes and is seen in patients with chronic infection, Hodgkin's disease, polycythemia vera and skin inflammation or any activity that increase epinephrine release such as stress or exercise.
- *Eosinophilia*—it is an increase in number of eosinophilic leukocytes and is seen in allergic reactions, skin disease, parasitic infection, leukemia, polycythemia, malignancy, and following irradiation.
- *Basophilic leukocytosis*—an increase is seen in myxedema, ulcerative colitis, chronic sinusitis, leukemia, polycythemia, Hodgkin's disease and following splenectomy.
- *Monocytosis*—it is seen in bacterial infection, recovery from acute infection and agranulocytosis, protozoal infection, lymphoma, leukemia, carcinoma of stomach breast cancer and high dose of steroid therapy.
- *Lymphocytosis*—it is seen in certain acute infections like brucellosis, tuberculosis, syphilis, leukemia and lymphosarcoma.

Qualitative Disorders of WBC

Lazy Leukocyte Syndrome

It is also called as '*Schwachman syndrome*'. It is a result of loss of chemotactic function of the neutrophil. The

neutrophils present in the blood cannot migrate to the site of tissue injury although phagocytic and bactericidal activities are normal.

Clinical Features

- *Age*—it becomes apparent at the age of 1-2 years when complication occurs due to infections.
- *Symptoms*—the most common clinical manifestations are stomatitis, otitis media and bronchitis.
- *Recurrent infection*—chances of recurrent infection in the patients are high.

Oral Manifestations

- *Stomatitis*—it is common oral finding of this disorder.
- *Periodontitis*—in some cases, periodontal disease may be present.

Diagnosis

- *Clinical diagnosis*—recurrent infection, periodontitis and stomatitis may give clue to diagnosis.
- *Laboratory diagnosis*—the total leukocyte count is slightly low but the absolute neutrophil count is as low as 100 to 200 cells/mm³. The bone marrow contains normal number of mature neutrophils.

Management

- *Antibiotics*—antibiotics are given to control the infection.

Chédiak-Higashi Syndrome

It is a congenital autosomal recessive defect of granulocytes and melanocytes. Abnormal granules are seen in all blood granulocytes resulting in decreased chemotactic and bactericidal activity.

Clinical Features

- *Albinism*—the characteristic clinical feature of this disease consists of oculocutaneous albinism.
- *Recurrent infection*—patient with Chediak Higashi syndrome will have recurrent infections of the respiratory tract and sinuses.
- *Gastrointestinal disturbance*—patient is having hepatosplenomegaly.
- *Lymph node enlargement*—there is cervical lymph node enlargement present in this patient.
- *Malignant lymphoma*—the disease may be associated with malignant lymphoma.
- *Other diseases*—there is photophobia, nystagmus, thrombocytopenia, and neurological problems.

Oral Manifestations

- *Ulceration*—ulceration of the oral mucosa is very common.
- *Periodontitis*—There may be loss of teeth due to periodontal disease.
- *Gingivitis and glossitis*—inflammation of gingiva and tongue are common occurrence.

Diagnosis

- *Clinical diagnosis*—albinism, recurrent infection, hepatosplenomegaly, oral ulceration and periodontitis will give clue to the diagnosis.
- *Laboratory diagnosis*—hematological studies show presence of giant abnormal granules in the granulocytes in the peripheral blood as well as in their precursors in the bone marrow.

Management

- *Antibiotics*—Immediate and proper treatment with antibiotics of the infection as soon as they occur is most important.
- *Other drugs*—vincristine, prednisolone and ascorbic acid have been tried as the treatment of this disorder.

Multiple Myeloma

It is described in Chapter 16: Malignant Tumor of Jaw.

Lymphoma

It is described in Chapter 16: Malignant Tumor of Jaw.

Leukemia

It is described in Chapter 16: Malignant Tumor of Jaw.

Chronic Idiopathic Neutropenia

It consists of group of diseases which includes familial neutropenia, chronic benign neutropenia, chronic neutropenia and hyperplastic neutropenia. Etiology is unknown, but they are characterized by a decrease in production of neutrophils in the bone marrow.

Clinical Features

- *Age and sex distribution*—it is seen in young adults and seen in predominantly in females.
- *Symptoms*—it is usually asymptomatic and free of infection which is due to compensatory monocytosis, which accounts of normal number of phagocytes at the site of tissue injury. In some cases recurring upper respiratory tract infections, otitis media, bronchitis and furunculosis can also occur.

Oral Manifestations

- *Periodontitis*—there is severe, rapidly advancing periodontal diseases.
- *Gingival finding*—gingivae appear intensely red with granulomatous margins. Severe gingival recession, advanced bone loss, mobility, denuded roots and loss of teeth.
- *Recurrent oral ulceration*—the second most common finding is recurring oral ulcers and in some cases, maxillary sinusitis can also occur.

Diagnosis

- *Clinical diagnosis*—it is not so specific.
- *Laboratory diagnosis*—the bone marrow of patients shows a normal number of immature cells but decrease in number of mature neutrophils. This is called as maturation arrest. Absolute neutrophils count may be below 500/mm³.

Management

- *Corticosteroids*—it is not required if the patient is asymptomatic. Patient who develops severe recurrent infections may benefit from alternate day corticosteroids therapy.

Platelet Disorders

Classification

Purpura

- Idiopathic thrombocytopenic purpura
- Secondary thrombocytopenic purpura
- Congenital purpura
- Thrombotic thrombocytopenic purpura
- Thrombocytopathic purpura
 - von-Willebrand's disease
 - Bernard-Soulier syndrome
 - Aldrich syndrome

Thrombocytosis

Thrombocytopenic Purpura

Purpura is defined as a purplish discoloration of the skin and mucous membrane due to subcutaneous and submucous extravasation of blood. Purpura may be due to deficient or defective platelets or due to an unexplained increase in capillary fragility.

It is also called as 'Werlhof's disease', 'purpura hemorrhagica' and 'primary thrombocytopenic purpura'. It is a disease in which there is an abnormal reduction in the number of circulating blood platelets with normal or raised number of megakaryocytes in the bone marrow. It is thought to be

an autoimmune disorder in which a person becomes immunized and develops antibodies against his own platelets. It can be a result of decrease in production of platelets or increased destruction of platelets or, both. Clinical features occur if platelet counts drop below $100,000/\text{mm}^3$.

Etiology

- **Idiopathic**—in some cases etiology is unknown causing the decrease in platelet production.
- **Reduced production**—it occurs due to infiltration of bone marrow by malignant cells. It can occur due cancer chemotherapeutic drugs.
- **Platelet destruction**—there may be increased in platelet destruction due to immunological causes. This can be caused by many drugs like heparin.
- **Increase consumption**—increase in consumption of platelet may occur in abnormal blood clot formation. This is seen in thrombotic thrombocytopenic purpura.
- **Spleen sequestration**—condition in which splenomegaly is present, large number of platelet are taken out for circulation.
- **Systemic disease**—some systemic disease like lupus erythematosus and HIV infection may cause purpura. Other diseases like leukemia, sarcoma, lymphoma, Hodgkin's disease myelofibrosis can also cause purpura.
- **Drugs**—barbiturates, analgesics (phenylbutazone and salicylates), antihistamine (diphenhydramine hydrochloride), myelosuppressive agents used in neoplastic disease.
- **Metabolic disease**—uremia, megaloblastic anemia can also cause purpura.
- **Others**—bone marrow replacement, radiation therapy can also cause purpura.

Clinical Features

- **Petechiae**—thrombocytopenic purpura is characterized by spontaneous appearance of purpuric hemorrhagic lesions of skin. The reason for this capillary is not able to seal off with thrombi. The patient also exhibits a bruising tendency.
- **Ecchymosis**—if large quantity of blood is extravasated Ecchymosis may result (**Fig. 37-14**).
- **Hematoma**—this can occur in rare case. It also occurs due to large amount of blood extravasated, which vary in size from tiny red pinpoint petechiae to large purplish ecchymosis and sometimes, even massive hematoma.
- **Other features**—epistaxis, hematuria and melena are common findings.
- **Intracranial hemorrhage**—intracranial hemorrhage is rare, but can be seen in children and the symptoms are headache, dizziness and confusion.

Fig. 37-14: Ecchymosis seen on hand in patient with thrombocytopenia purpura.

- **Congenital purpura**—it may result from placental transfer of platelet antibodies. Such antibodies may arise from active immunization of the mother by fetal antigens or from passive transfer of auto-antibodies present in the maternal circulation. In infants, it is first seen at about one to two weeks of age. This disorder is frequently mild or even subclinical. Some cases show generalized petechiae and ecchymosis. In some infants, hemorrhage can be severe and intracranial hemorrhage may result in death. As the responsible antibodies disappear from the circulation platelet count returns to normal within 1 to 4 weeks.
- **Thrombotic thrombocytopenic purpura**—it is immunologically mediated. It is characterized by occlusion of small arterioles and capillaries of many organs by thrombi formed of fibrin and platelets. It generally occurs in young adults and more commonly in females than in males. There is thrombocytopenia, hemolytic anemia, fever, transitory neurologic dysfunction and renal failure.

Oral Manifestations

- **Site**—submucous petechiae and ecchymosis commonly occur especially at the junction of the hard and soft palate (**Fig. 37-15**). In some cases, it can be seen on tongue.
- **Bleeding after tooth extraction**—the first manifestation of the disease can be seen in oral cavity in the form of excessive bleeding after tooth extraction.
- **Petechiae**—it appears as numerous tiny, grouped clusters of reddish spots, only a millimeter or less in diameter. Petechiae do not blanch on pressure which is the distinguishing feature between purpura and telangiectasia.
- **Gingival bleeding**—in severe cases, extensive spontaneous gingival bleeding may be seen and this may form foci of secondary infection.
- **Tongue**—in some cases, petechiae and ecchymosis can be seen on the tongue (**Figs 37-16A and B**).

Fig. 37-15: Thrombocytopenic purpura showing petechiae at the junction of hard and soft palate.

Figs 37-16A and B: Petechial hemorrhage seen on tongue in patient with thrombocytopenic purpura.

Diagnosis

- **Clinical diagnosis**—petechiae at the junction of hard and soft palate is clue to the diagnosis (**Fig. 37-17**).

- **Laboratory diagnosis**—the platelet count is usually below 60,000 cells per cu mm. The bleeding time is prolonged but, the clotting time is normal. The bone marrow reveals megakaryocytic hyperplasia. When severe bleeding occurs, there may be associated iron deficiency anemia.

Fig. 37-17: Petechiae seen at the junction in hard palate area as pinpoint purplish lesion.

Management

- **Young children**—in young children, treatment is seldom necessary unless there is intracranial evidence of bleeding.
- **Corticosteroids**—in adults, prednisone 60 mg/dl should be given until the platelet count rises to normal level when, the dose should be cautiously tapered until the drug is withdrawn.
- **Splenectomy**—if there is no response to prednisolone in 3 to 4 days, splenectomy is indicated.
- **Transfusion**—platelet transfusion can be given.
- **Removal of cause**—in case of secondary thrombocytopenia purpura, this will reduce the symptoms and sign of lesion.
- **Local hemostasis**—the spontaneous gingival hemorrhage can often be controlled by the local use of hemostatic of the non-causing type, such as fibrin foam, Gelfoam or absorbable cellulose with thrombin. Sometimes, 1.5% hydrogen peroxide mouth wash will stop gingival bleeding.

Von Willebrand's Disease

It is also called as '*pseudohemophilia*', '*vascular hemophilia*' and '*vascular purpura*'. It is rare disorder which is inherited as an autosomal dominant trait in which there is defect in all three components of the hemostatic mechanism; the capillaries, platelets and coagulation mechanism. It is most common hereditary clotting disorder. In it, there is

quantitative and qualitative deficiency in larger molecule portion of factor VIII molecule. Von Willebrand's factor activity is responsible for platelet adhesion to subendothelium, regulation of the plasma level of factor VIII coagulant activity and thereby normal hemostasis.

Clinical Features

- *Age and sex distribution*—it is seen in childhood and adults and females are affected more commonly than males.
- *Bleeding tendencies*—excessive bleeding either spontaneously or following even minor trauma is the chief feature of the disease. Bleeding into the gastrointestinal tract, epistaxis and severe menorrhagia are also common. The most common sites of bleeding are nose, skin and gingiva. Bleeding tendencies usually appear early in childhood and decrease in middle and old age.

Oral Manifestations

- *Gingival bleeding and post-extraction bleeding*—gingival bleeding and post-extraction bleeding are the most common oral manifestations. The disease may be discovered after dental extraction.

Diagnosis

- *Clinical diagnosis*—bleeding tendencies either spontaneous or after slight trauma may give clue to the diagnosis.
- *Laboratory diagnosis*—there is prolonged bleeding time, normal platelet count, failure of aggregation of platelets impaired adherence of platelets and depressed levels of factor VIII are suggestive of this disorder. There is low Anti-hemophilic globulin (AHG) levels and abnormal platelet retention to glass beads. The platelet count and prothrombin consumption are normal. The clotting time usually is normal but capillary fragility is increased.

Management

- *Transfusion*—Bleeding episode is best controlled by transfusion of plasma and or cryoprecipitate and by local control of homeostasis.
- *Avoid giving aspirin*—patients with von Willebrand's disease should not be given aspirin because of prolongation of the bleeding time that may occur.
- *Desmopressin*—it is given as nasal spray to control nasal bleeding.

Aldrich Syndrome

It is also called as 'Wiskott-Aldrich syndrome'. It is X-linked recessive condition. It is characterized by thrombocytopenia.

Clinical Features

- *Symptoms*—patients commonly manifest boils, otitis media, bloody diarrhea and respiratory infection.
- *Increased susceptibility to infection*—there is eczema and increased susceptibility to infection.
- *Malignant lymphoma*—there is common occurrence of malignant lymphoma, which is an important feature of this disease.
- *Bleeding*—bleeding occurs from nose, skin and gastrointestinal tract.

Oral Manifestations

- *Palatal petechiae*—palatal petechiae are frequently present.
- *Spontaneous bleeding*—there is spontaneous bleeding from the gingiva.

Diagnosis

- *Clinical diagnosis*—increase susceptibility to infection, spontaneous bleeding, and malignant lymphoma may give clue to diagnosis.
- *Laboratory diagnosis*—prolonged bleeding time, anisocytosis, alteration in the size and shape of platelets with most platelets smaller than normal. There is decreased production and defective maturation of platelets since normal megakaryocytes may be seen in the marrow.

Management

- *Antibiotics*—patients are given antibiotics to control the infection.
- *Hemostasis*—local hemostasis to control gingival bleeding should be done.

Familial Thrombasthenia

It is also called as 'Glanzmann's disease'. It is hereditary, chronic hemorrhagic disease transmitted as an autosomal recessive trait. There is defective platelet aggregation due to defective membrane protein.

Clinical Features

- *Sex distribution*—both sexes may be affected and onset of menarche may be a critical event.
- *Severe bleeding*—there is excessive bleeding, either spontaneous or following minor trauma.
- *Sign and symptoms*—purpuric hemorrhages of skin are common, as are epistaxis and gastrointestinal bleeding. Hemarthrosis is also noted in some cases.

Oral Manifestations

- *Spontaneous gingival bleeding*—spontaneous bleeding from the oral cavity particularly gingival bleeding.

Diagnosis

- *Clinical diagnosis*—severe excessive bleeding, epistaxis and hemarthrosis can be present.
- *Laboratory diagnosis*—bleeding time is prolonged while clot retraction is impaired. Platelet count is normal as the clotting time. The aggregation of platelet by epinephrine, ADP and thrombin is defective.

Management

- *Platelet infusion*—no specific treatment but patient in oral surgery can be given microfibrillar collagen preparation with fibrinolytic inhibitors.

Onyiai

It means blood blister. It is variant of idiopathic thrombocytopenic purpura because of its similarities to hematological manifestations. It is thought to be linked to the traditional diet and lifestyles prevalent in primitive societies of Southern and East African countries.

Clinical Features

- *Age and sex distribution*—individuals in the second decade of life seen most commonly affected although, the disease can develop any time after the first 6 months of life. There is female predilection.
- *Onset*—the sudden appearance of hemorrhagic bullae on the skin and oral mucosa followed by epistaxis or frank bleeding from mouth.
- *Signs and symptoms*—there is also subconjunctival hemorrhages, hematemesis, melena, hematuria, vaginal bleeding and CNS hemorrhage. Hemorrhagic episodes may be multiple and recurrent attacks result in anemia.

Diagnosis

- *Clinical diagnosis*—sudden hemorrhagic bulla appearance will give clue to diagnosis.

Management

- *Drug management*—corticosteroid therapy, blood transfusion and platelet transfusion

Thrombocytosis or Thrombocythemia

It is characterized by an increase in the number of platelets in the blood in excess of 1000×10^6 /dl. It is of two types, i.e. primary and secondary.

It is caused by polycythemia and myeloid leukemia, anemia, tuberculosis, sarcoidosis, hyperadrenalism, rheumatoid arthritis, and bronchial carcinoma.

Clinical Features

- *Age*—it is a rare disorder of the elderly associated with a tendency to bleed and to have thrombotic episodes.
- *Epistaxis*—epistaxis, bleeding into the gastrointestinal tract as well as bleeding into the genitourinary tract and central nervous system is common.
- *Skin hemorrhage*—hemorrhages in skin are also common.

Oral Manifestations

- *Gingival bleeding*—spontaneous gingival bleeding and excessive and prolonged bleeding after extraction of tooth is also common.

Diagnosis

- *Clinical diagnosis*—epistaxis and gingival bleeding will give clue to diagnosis.
- *Laboratory diagnosis*—the platelet count is increased and there is abnormal aggregation in response to several aggregating agents. The clotting time and prothrombin time are normal but bleeding time is frequently prolonged.

Management

- *Drug management*—certain cytotoxic drugs, heparin, corticosteroid and aspirin in small dose may help to counteract the thrombotic tendency.
- *Radioactive phosphorus*—it responds to radioactive phosphorus.

Hemorrhagic Disorders

Hemophilia

Hemophilia stands for hemo (blood), philia (loving). It is a hereditary disorder of blood coagulation characterized by excessive hemorrhage due to a prolonged coagulation time. Deficiency of factor VIII or anti-hemophilic factor is the cause of hemophilia. It is transmitted as X-linked recessive character carried on X-chromosome. The males are clinically affected and the females are carriers of the trait. Hemophilia A occurs 10 times more commonly than hemophilia B. Traumatic injury of the oral cavity may lead to the diagnosis of hemophilia.

Hemophilia B is also called as 'Christmas disease'. It occurs due to hereditary deficiency of factor IX or functionally defective factor IX. It is transmitted as X-linked recessive character through chromosome. It is very rare, compared to hemophilia A.

Types (according to AHG factors)

- *Mild*—less than 4% of AHG

- *Moderate*—1% to 3% of AHG
- *Moderate to severe*—0.0% to 0.9% of AHG
- *Severe*—0% of AHG

Clinical Features

- *Age and sex distribution*—these manifestations usually begin after 6 months of age, when the child begins to move about and tends to fall and sustain injuries, i.e. when spontaneous hemorrhage is noted by the parents.
- *Joint hemorrhage or hemarthrosis*—the most common manifestation is hemorrhage into joints which is spontaneous and associated with warmth and muscle spasm. Repeated episodes cause damage to the joint with wasting of the related muscle, leading to deformity and crippling.
- *Subcutaneous hemorrhage*—hemorrhage into subcutaneous tissues, internal organs and musculature also are frequent and potentially disabling complications. Superficial trauma gives rise to uncontrolled bleeding.
- *Intracranial bleeding*—intracranial bleeding is relatively rare unless associated with trauma.
- *Pseudotumor of hemophilia*—in some cases tissue hemorrhage can lead to formation of tumor-like mass.

Oral Manifestations

- *Site*—the anatomic sites involved in persistent oral bleeding are the frenum of lip and the tongue.
- *Symptoms*—there is prolonged bleeding after tooth extraction.
- *Hematoma of floor of mouth*—hematoma of the floor of mouth may occur and blood may spread via the fascial spaces and produce a hematoma of the larynx, with consequent respiratory embarrassment.
- *Tooth eruption*—physiological processes of tooth eruption and exfoliation may be associated with severe and prolonged hemorrhage.
- *Gingival hemorrhage*—gingival hemorrhage may as a result of gingival injury (Fig. 37-18).

Diagnosis

- *Clinical diagnosis*—extensive bleeding after extraction of tooth and routine periodontal procedure should suspect hemophilia.
- *Laboratory diagnosis*—clotting time is prolonged, but however the bleeding time, platelet count and prothrombin time are all normal. The prothrombin consumption time and the partial thromboplastin time may be prolonged in severe cases.
- *Difference between hemophilia A and hemophilia B*—in the laboratory, hemophilia A may be differentiated from hemophilia B by modification of the prothrombin consumption time or the partial thromboplastin time.

Fig. 37-18: Gingival hemorrhage seen in hemophilia patient.

Management

- *Fresh frozen plasma*—replacement therapy of fresh frozen plasma should be given. Hypovolemia, allergic reaction, transfusion hepatitis, hemolytic anemia and development of factor VIII antibodies are complications with fresh frozen plasma.
- *Factor VIII concentrates*—the dose and duration of administration of factor VIII concentrates are planned, taking into consideration of the site and the type of bleeding.
- *Prevention of complication*—to reduce complications caused by cryoprecipitate or plasma various drugs are used instead of factor VIII products, before dental extraction, e.g. a synthetic analogue of anti-diuretic 1-deamino-8-d-arginine vasopressin (DDAVP) in combination with tranexamic acid and Epsilon aminocaproic acid (EACA) can be given.
- *Genetic counseling*—it should be provided to patient to know importance of inheritance.

Dental Management of Hemophilia A and Hemophilia B

- *Anesthesia*—local anesthesia is contraindicated in severe hemophiliac patients with prior replacement therapy. If to be given, it should be intrapulpal anesthesia, intra-ligamentary (periodontal) and papillary injection. Sedation with diazepam or NO₂/O₂ analgesia can be given.
- *Endodontic therapy*—common endodontic procedure is quite acceptable provided care is taken not to exceed beyond the apex of tooth. Hemorrhage into the canal can usually be controlled with 1:1000 aqueous epinephrines on an endodontic paper point.
- *Restorative*—it can be carried out in hemophiliac patient, but the rubber dam must be used to prevent trauma to

gingiva and other soft tissues. When use of rubber dam is not practical, an epinephrine impregnated hemostatic cord is placed in the gingival sulcus before preparation of the crown or inlay margins.

- *Prosthodontics therapy*—complete dentures are well tolerated in hemophilic patients. Partial dentures are also well tolerated, as long as the patient maintains meticulous oral hygiene because clasp can trap food debris, resulting in gingivitis and subsequent hemorrhage.
- *Periodontic therapy*—conservative periodontal treatment is generally more desirable than gingival and osseous surgery because of hospitalization and extensive amount of replacement therapy necessary with surgery.
- *Oral surgical procedure*—Local homeostatic agents and techniques include pressure surgical packs, oxidized cellulose saturated with bovine thrombin solution, vasoconstrictors, suture, topical thrombin and use of absorbable homeostatic. After packing, the tooth socket must be protected by mechanical splint to prevent disturbance to the clot. Postoperative use of anti-fibrinolytic agent and adherence to soft diet are further advocated to support clot maintenance.
- *Drugs precaution*—aspirin and other NSAIDs are avoided in patients with bleeding disorders owing to inhibition of their platelet function. Intramuscular injection should also be avoided because of risk of hematoma formation.
- *Electrosurgery*—electrosurgery is not recommended because it causes tissue necrosis and possible subsequent hemorrhage.

Factor V Deficiency or Parahemophilia

It is a rare hemorrhagic disorder, clinically similar to hemophilia, caused by a deficiency of factor V or proaccelerin.

Clinical Features

- *Age and sex distribution*—it is inherited as an autosomal dominant trait affecting both sexes.
- *Symptoms*—spontaneous epistaxis, bleeding into the gastrointestinal tract and menorrhagia are common.
- *Cutaneous lesion*—cutaneous ecchymosis and hamartomas are frequently seen, although petechiae are rare.
- *Others*—intraocular hemorrhage and hemorrhage into the central nervous system have been also reported.

Oral Manifestations

- *Gingival bleeding*—spontaneous gingival bleeding occurs in some cases and prolonged bleeding after extraction of tooth is observed.

Diagnosis

- *Clinical diagnosis*—spontaneous epistaxis, intraocular hemorrhage with gingival bleeding.
- *Laboratory diagnosis*—both clotting and prothrombin time are prolonged but, bleeding time is normal. The basic defect is reduction in plasma proaccelerin.

Management

- *Transfusion*—transfusion and freshly frozen plasma are given when there is excessive hemorrhage.

Hypofibrinogenemia

It is uncommon disease in which patient has little or no fibrinogen present, in either his plasma or tissue.

Types

- *Congenital*—it is rare and autosomal recessive trait.
- *Acquire*—it occurs secondary to increase in fibrinogen consumption during intravascular clotting, defective fibrinogen formation and destruction or digestion of fibrinogen by fibrinolytic or proteolytic enzymes circulating in the bloodstream.

Clinical Features

- *Sex*—it occurs in both sexes with slight predilection for males.
- *Symptoms*—patients exhibit severe bleeding episodes throughout their lives and the disease is clinically indistinguishable from hemophilia. There is also epistaxis, bleeding into gastrointestinal tract and central nervous system has been also reported.
- *Cutaneous lesion*—cutaneous ecchymosis and hamartomas are frequently seen, although petechiae are rare.

Oral Manifestations

- *Gingival bleeding*—spontaneous gingival bleeding and prolonged bleeding, after extraction of tooth is observed.

Diagnosis

- *Clinical diagnosis*—it is not possible to differentiate it from hemophilia clinically.
- *Laboratory diagnosis*—bleeding time may be normal or slightly prolonged but prothrombin time and clotting time are infinite.

Management

- *Transfusion*—there is no specific treatment for the disease except for transfusion, particularly of concentrated fibrinogen during bleeding episodes.

Macroglobulinemia

It is also called as 'macroglobulinemia of Waldenstrom'. It is a plasma cell dyscrasia showing hemorrhagic tendency similar to other hemorrhagic diseases. The formation of complex between the abnormal immunoglobulin M, macroglobulin and clotting factors, thereby inactivating the clotting factors is responsible for hemorrhage.

Etiology

- *Multiple myeloma*—it is a variant of multiple myeloma.
- *Bing-Neel syndrome*—Bing-Neel syndrome (hyperglobulinemia with central nervous system involvement on toxic-infectious basis).
- *Plasmacytoma*—it is also a variant of plasmacytoma.
- *Immunological*—it is an altered immunologic basis.

Clinical Features

- *Age and sex distribution*—it is most common in persons over age of 50 years, seldom under 40 years and males and female affected equally.
- *Signs and symptoms*—the chief clinical signs are weakness, weight loss, pallor, lymphadenopathy, hepatomegaly, epistaxis, subarachnoid, and ocular hemorrhage.

Oral Manifestations

- *Spontaneous gingival hemorrhage*—it consists of spontaneous gingival hemorrhage, often with continued oozing of blood.
- *Oral ulcer*—bleeding oral ulcers on tongue, palate, buccal mucosa or gingiva and focal areas of hyperemia which appear edematous are painful.

Diagnosis

- *Clinical diagnosis*—oral ulcer, gingival bleeding, lymphadenopathy, weakness, and hepatomegaly will give clue to diagnosis.
- *Laboratory diagnosis*—it generally manifests severe anemia with hemoglobin level near 4 to 6 gm/dl. An extremely elevated sedimentation rate with demonstrable euglobulins and frequent gelling of the serum upon cooling to room temperature or lower are cooling. The viscosity of blood serum is high. The WBC count, clotting time, bleeding time and prothrombin time are normal but lymphocytosis, neutropenia and thrombocytopenia are occasionally seen.

Management

- *Chlorambucil*—chlorambucil, in high doses, provides prolonged remission in these patients.

- *Plasmapheresis*—repeated plasmapheresis has often been used for temporary treatment.

Hereditary Hemorrhagic Telangiectasia

It was first described by Osler in 1901 and it frequently bears his name (*Osler-Rendu-Weber syndrome*). It is transmitted as an autosomal dominant trait and characterized by bleeding from mucous membrane and telangiectatic lesions on skin and mucosa. Telangiectasia represents permanently enlarged capillaries that are localized superficially, just under the skin and mucosa.

Clinical Features

- *Age*—the lesion may be present in childhood but more often appear in puberty and become progressively worse with increasing age.
- *Site*—they are found most commonly on the skin of the face, finger, toes, and on the oral mucous membrane.
- *Appearance*—the disease is characterized by multiple localized angiomas or telangiectases on the skin.
- *Signs*—the lesion bleeds easily, even after slightest trauma. Bleeding is not caused by clotting factor deficiency but as a result of rupture of the weak capillaries. The lesion blanches on pressure and regains its color when the pressure removed. As the affected individual grows, the bleeding episode tends to increase in frequency and intensity.
- *Crushed spider appearance*—the typical lesion is cherry-red to purplish macule or small papule (**Fig. 37-19**) that resembles a *crushed spider*.
- *Epistaxis*—they often give rise to profuse hemorrhage, such as episodes of epistaxis. Severe bleeding may also occur from the gastrointestinal tract.

Fig. 37-19: Cherry red lesion seen on lower chin area in hereditary hemorrhagic telangiectasia.

Oral Manifestations

- *Site*—oral cavity, lips and tongue are most commonly affected.

- *Symptoms*—Severe oral hemorrhage may be experienced several times a day for weeks. At times there is gush of blood when involved areas are simply touched with cotton.
- *Appearance*—cherry red, often slightly raised, pinpoint or slightly larger lesions resembling a crushed spider is seen at any intraoral site, especially at the lip.
- *Hemorrhage during treatment*—hemorrhage can be encountered during dental treatment which encroach the affected area.

Diagnosis

- *Clinical diagnosis*—cherry red lesion seen on mucosal site may suspect this disease.
- *Laboratory diagnosis*—intrinsic defect in the endothelial cells permitting their detachment or defect in the perivascular supportive tissue bed, which weakens the vessels.

Management

- *Septal dermoplasty*—it is done in patient who has got repeated attacks of epistaxis. In this involve mucosa is removed and replaced by skin graft.
- *Pressure pack*—spontaneous hemorrhages may be controlled by pressure packs, particularly nasal bleeding.
- *Sclerosing agents*—sclerosing agent such as sodium morrhuate or sodium tetradecyl sulfate injected into the lesion is useful.
- *Electrocautery*—electrocautery is also useful, prophylactically in a lesion that is likely to cause bleeding.
- *LASER ablation*—it is also useful in some cases.
- *Other therapy*—other therapy like progesterone, estrogen, iron replacement therapy and occasionally blood transfusion is also indicated in severe patient.

Rare Hemorrhagic Disorders

- *Hypoprothrombinemia*—it is seen not only as a result of prothrombin deficiency but also due to factor V, VII, X and fibrinogen deficiency and when circulating inhibitors are present. The symptoms are similar to those of mild hemophilia. The amount of bleeding is variable and is usually brought about by trauma.
- *Factor XI deficiency or hemophilia C*—it is rare and regarded as an autosomal dominant trait. The bleeding tendency is erratic, but there is always the possibility of severe bleeding after minor surgical procedures, even though the patient may undergo numerous previous surgical procedures uneventfully.
- *Fibrin stabilizing factor deficiency*—it appears to be transmitted as autosomal recessive trait with high incidence of consanguinity. In the absence of this factor,

there are permanent peptide bonds between fibrin molecules so that fibrinogen monomer aggregates break up under certain conditions. Patients with this deficiency have severe post-surgical bleeding episodes which are typically delayed from 24 to 36 hours, hemoarthrosis and defective wound healing. Bleeding and clotting time are normal. Treatment is given prior to surgery by administration of factor XIII in small amounts.

- *Disseminated intravascular coagulation (DIC)*—it is an acquired bleeding disorder which is generally acute but may be chronic in onset in certain instances. The acute DIC is clinically severe with depletion of multiple clotting factors like fibrinogen, prothrombin, factor V and factor VIII and platelets are also reduced in number.
- *Hemangiomata*—these are congenital malformations and lesions are larger than hereditary hemorrhagic telangiectasia and tend to decrease in size at puberty. Larger malformation may persist through adult life. The lesion may vary in size, being unobstructive as macules or as predominant as pedunculated lesion. The macular lesions are less prone to hemorrhage. The macular lesion may occur anywhere in the oral cavity like on lip, gingiva, tongue, buccal mucosa or within the jaw bones. There is presence of mobile teeth, bleeding from the gingival crevice and expansion of the cortex of jaw bones in areas of involvement. Therapy can entail the use of Sclerosing agents such as sodium tetradecyl or morrhuate sodium injected into the lesion.
- *Hemorrhage of iatrogenic cause*—it may occur due to anti-coagulation therapy which is given in acute myocardial infarction, cerebrovascular accident, pulmonary embolism. Two types of anti-coagulants are used: heparin and the bishydroxycoumarin derivatives, which are used much more commonly than heparin in ambulatory patients. If patients are taking heparin, topical thrombin can be used to control hemorrhage due to dental treatment. If necessary, the heparin dose can be regulated under the able guidance of patient's physician. In an emergency, profuse hemorrhage can be controlled by factor IV protamine. If patients are taking bishydroxycoumarin, topical thrombin can be used to control hemorrhage. The action of bishydroxycoumarin derivatives may be reversed by giving intramuscular vitamin K1 but it takes about 12 to 24 hours for this reversal. In an emergency situation, patients are given plasma transfusion to restore the missing factors.

Water soluble

- Vitamin B complex
 - Vitamin B₁ (thiamine)
 - Vitamin B₂ (riboflavin)
 - Vitamin B₃ (niacin)
 - Vitamin B₅ (pantothenic acid)
 - Vitamin B₆ (pyridoxine)
 - Vitamin B₈ (biotin)
 - Vitamin B₉ (folic acid)
 - Vitamin B₁₂ (cyanocobalamin)
- Vitamin C (ascorbic acid)
- Choline
- Inositol

Fat-soluble

- Vitamin A
- Vitamin D
- Vitamin E
- Vitamin K

a precursor steroid, niacin from tryptophan which is an essential amino acid, vitamin K and biotin by intestinal microflora.

Deficiency of vitamins may be primarily due to vitamin deficient diet or secondarily because of disturbances in intestinal absorption, transport in blood, tissue storage or metabolic conversion.

Causes of Vitamin Deficiency

- *Decreased intake*—decreased amount of intake of essential nutrients.
- *Impaired absorption*—impaired absorption from the alimentary tract.
- *Increased metabolism*—increased metabolism due to rapid growth.
- *Inadequate storage*—inadequate storage, fever and pregnancy.

Introduction

Vitamins are organic substances in food which are required in small amounts but which can not be synthesized in adequate quantities in the body and which are soluble in either fat or water. Vitamins are needed in small quantities to act as a cofactor in a variety of metabolic reactions. Your body needs only small amounts of vitamins. But because what the body manufacture is often not enough, these must be obtained from your diet and from supplements.

Vitamins occur in a natural and in a physiologically inactive form and are called as *provitamins*. They become activated only after conversion within the animals. For example, vitamin A exists in plants in the form carotene, which is activated in the liver.

Small amounts of vitamins can be synthesized endogenously. For example vitamin D is synthesized from

Water Soluble Vitamins

Water-soluble vitamins are found in yeast, grain, rice, vegetables, fish and meat. They are essential co-enzymes required in energy releasing mechanisms and in hemopoiesis. They also act as co-enzymes for metabolism of proteins, carbohydrates and fats.

B-complex Vitamins

Most of B-complex occurs in nature in the bound form within the cells of vegetables or animal tissues. The digestion for the liberation of vitamins and its absorption is a result of breakdown of cellular structures in the gut. Vitamin B-complex is not stored in appreciable amounts in the body tissues except vitamin B₁₂. Excretion of vitamins occurs in the kidney.

The oral signs of deficiency of vitamin-B occur in the oral tissues like tongue, mucous membrane and gingiva. It may result in dermatitis, stomatitis and gastritis and blood and bone marrow disorders. Degenerative changes of brain and nerves are also a characteristic feature of deficiency since nerve tissue depends on glucose. In hemopoiesis, vitamin B₁₂ and folate are essential for maturation of red cell precursors.

Thiamine (Vitamin B₁)

It is a vitamin for calm nerves. It is also known as 'aneurin'. It was discovered by Eijkman in 1897. It is a colorless basic organic compound composed of a sulfated pyrimidine ring.

Absorption and excretion

It is readily absorbed from both small and large intestines. The capacity of the human intestine to absorb this vitamin is limited to about 5 mg per day. It is phosphorylated by the liver and kidneys. In tissues, it is found as thiamin pyrophosphate.

Thiamin pyrophosphate is a coenzyme for decarboxylation of pyruvate to acetyl coenzyme A. Any excess supply of thiamine is excreted in the urine.

Sources (Fig. 38-1)

- *Cereals*—wheat germ, wheat flour and rice bran.
- *Pulses*—Soya beans, split Bengal gram, lentil, moth, dry beans and split red gram.
- *Vegetables*—lotus stems, capsicum and turnip greens.
- *Nuts and oilseeds*—groundnuts, pistachio nuts and mustard seeds.
- *Fruits*—apricots, pineapple and bael fruits.
- *Meat*—whole meat, pork and liver sheep.
- *Milk and milk products*—skimmed milk powder, cow's milk and khoa.

Fig. 38-1: Sources of vitamin B₁.

Daily requirements

- *Men*—1.3 mg daily
- *Women*—1.0 mg daily
- *Children*—1.1 mg daily
- *Pregnancy and lactation*—2 mg daily

Functions in the body

- *Growth*—it promotes growth, protects heart muscle and stimulates brain action.
- *Nervous system*—it plays an important role in the normal functioning of the entire nervous system.
- *Digestion*—it aids in digestion especially that of carbohydrates.
- *Diuretic*—it is a mild diuretic and it increases urine formation.
- *GIT*—it improves peristalsis and helps prevent constipation.
- *Blood cells*—it maintains the normal blood count and improves circulation.
- *Others*—it also reduces fatigue, increases stamina, prevent premature aging and senility by increasing mental alertness and promotes a healthy skin.

Deficiency symptoms

- *Nervous disorders*—when cells cannot metabolize the glucose aerobically, it affects the nervous system first since it depends entirely on glucose for its energy requirements. There is mental depression, nervous exhaustion and insomnia.
- *Digestive symptoms*—it occurs due to defective hydrochloric acid production in the stomach. Patient complains of loss of appetite, poor digestion, chronic constipation and loss of weight.
- *Heart*—there is accumulation of pyruvic acid and lactic acid derived from it, which produces vasodilatation and increases cardiac output. The heart muscle becomes lazy and fatigued and the auricles or the upper chambers of the heart lose their strength and it gradually enlarges. It may lead to a condition known as 'hypertrophy of the heart'.
- *Beriberi*—prolonged gross deficiency can cause beriberi. There are three types of beriberi-
 - Wet beriberi
 - Dry beriberi
 - Infantile beriberi
- *Others*—other diseases, which can be associated with it are
 - Wernicke's encephalopathy
 - Peripheral neuritis
 - Korsakoff's psychosis

Beriberi

It is marked by cardiac dilation with four chamber enlargement, pallor and flabbiness of myocardium.

Etiology

- **Diet**—it is caused due to eating polished rice in which outer husks is removed which contain thiamine.
- **Alcoholics**—it is commonly seen in chronic alcoholics due to their poor nutrition in general and also because alcohol interferes with intestinal absorption of thiamine.
- **Others**—it is often precipitated by infection, pregnancy and lactation.

Pathogenesis

- Deficiency of thiamine →incomplete metabolism of glucose →accumulation of pyruvic acid and lactic acid in tissue and body fluid →dilation of peripheral blood vessels →fluid may leak out through capillaries, producing edema →high cardiac output, heart dilation.

Clinical Features**Wet beriberi**

- **Symptoms**—pain in legs after walking due to accumulation of lactic acid.
- **Cardiac signs**—there is tachycardia and increased blood pressure, cardiomegaly, increased JVP and palpitations. There is also presence of sinus tachycardia and inverted T waves.
- **Skin**—skin is warm due to vasodilation.
- **Others**—edema may develop rapidly to involve leg, face and trunk.

Dry beriberi

- **Peripheral neuropathy**—peripheral neuropathy is a common feature of this disease.
- **Wasting of muscle**—in long standing cases, there is degeneration and demyelination of both sensory and motor nerve fibers resulting in severe wasting of muscles.

Oral manifestations

- **Hypertensive mucosa**—there is hypersensitivity of oral mucosa.
- **Symptoms**—pain in the tongue, teeth, jaws and face.

Management

- **Complete rest**—patient should advice the complete rest.
- **Thiamine**—thiamine 50 mg IM for 3 days then 10 mg 3 times daily by oral route.
- **Management of infantile beriberi**—infantile beriberi is treated via mother's milk. The mothers should receive 10,000 mcg twice daily. In addition, infants should be given thiamine in doses of 10,000 to 20,000 mcg IM once in a day for 3 days.
- **Precaution while giving thiamine to patient**—As such there are no toxic effects of thiamine. Any excess is excreted in the urine and not stored in any degree in the tissues or organs. Rare symptoms of overdose are tremors, herpes, edema, nervousness, rapid heartbeats and allergies. In rare cases, excessive supply of this vitamin may also adversely affect thyroid and insulin production.

Other deficiency symptoms

- **Wernicke's encephalopathy**—it is commonly seen in alcoholics with persistent vomiting. There is a classical triad of ocular abnormalities, ataxia and confusion. There are facial symmetrical areas of grayish discoloration. There is also bilateral symmetrical ophthalmoplegia and ataxia. Injection of thiamine should be given. 50 mg by slow intravenous injection followed by 50 mg daily by oral route for a week.
- **Korsakoff's psychosis**—in it, there is a predominant abnormality in mental function which is memory defect. There is profound impairment of memory recall and new learning ability.

Riboflavin (Vitamin B₂)

It is also called as the 'beauty vitamin'. It is a yellowish green fluorescent compound soluble in water. The word riboflavin is derived from two sources ribose, referring to ribose sugar found in several vitamins and enzymes and flavin meaning yellow. It is an essential component of coenzyme flavin mononucleotide and flavin adenine dinucleotide, involved mainly in a wide variety of oxidation-reduction reactions. It is stable to boiling in an acidic solution. It is decomposed by heat. It is also destroyed by ultraviolet light.

Absorption and excretion

It is readily absorbed from the intestinal tract and is phosphorylated in the wall of the intestine. It carried to the tissue of the body and incorporated into the cells enzymes. It is stored in liver, kidneys and heart. Riboflavin is excreted primarily in the urine and bile and sweat are other minor routes of excretion.

Sources (Fig. 38-2)

- **Cereals**—wheat germ, rice bran, bajara and barley.

Fig. 38-2: Sources of vitamin B₂.

- *Pulses and legumes*—Soya beans, red gram, split green gram and peas.
- *Vegetables*—lotus stems, turnip greens, spinach, cauliflower and brinjals.
- *Nuts and oilseeds*—almonds, walnuts, chilgozas and mustard seeds.
- *Fruits*—papayas, raisins, custard apples and jack fruits.
- *Milk and milk products*—skimmed milk powder, cow's milk and whole milk powder.
- *Animals*—liver of sheep, eggs, mutton and prawn.

Daily requirement

- *For infants*—60 mcg value per kg of body weight daily.
- *Men*—1.5 mg daily
- *Women*—1.2 mg daily
- *Children*—1.3 mg daily
- *Pregnancy and lactation*—2 to 2.3 mg daily

Function in the body

- *Growth*—it is essential for growth and general health.
- *Metabolism*—it is involved in the metabolism of carbohydrates, fats and proteins. It is essential for normal tissue maintenance.
- *Nervous system*—it helps in functioning of the nervous system.
- *Digestion*—it helps in digestion and prevents constipation.
- *Eyes*—it alleviates eye strain and it is helpful in counteracting the tendency toward glaucoma.
- *Others*—it promotes a healthy skin, nails and hair and strengthens the mucous lining of the mouth, lips and tongue.

Causes of deficiency

- *Primary deficiency*—it occurs due to inadequate diet and also inadequacy of other essential nutrients including vitamins and proteins.
- *Secondary deficiency*
 - It may occur due to diseases of the intestinal tract.
 - Prolong use of psychological drug that interfere with production of flavin monophosphate.
 - Chronic alcoholism, burns and trauma.

Deficiency symptoms

- *Seborrheic dermatitis*—it affects the nasolabial fold and ala of the nose which exhibits a scaly gray dermatitis and consists of enlarged follicles around the side of the nose which is plugged with dry sebaceous material.
- *Ocular changes*—it consists of corneal vasodilatation, photophobia and superficial and interstitial keratitis. There may be itching and burning of the eyes.
- *Skin and nails*—it may also result in dull or oily hair, an oily skin, premature wrinkles on the face and arms and split nails.

- *Others*—malfunctioning of adrenal glands, anemia, vaginal itching and cataract.

Oral manifestations

- *Glossitis*—glossitis which begins with soreness of lateral margins of the tongue. Filiform papillae become atrophic while fungiform papillae remain normal or become engorged and mushroom shaped giving the tongue a reddened coarsely granular appearance. In severe cases, the tongue becomes glazed and smooth due to complete atrophy of the papillae and exhibits a magenta color.
- *Cheilitis*—lips become red and shiny because of desquamation of epithelium. Paleness of lips and cheilitis which is seen as maceration and fissuring at the angle of the mouth (**Fig. 38-3**). There is maceration at angle of mouth with pain on the opening mouth; it again results in fissuring and cracking with ulceration. As the disease progresses, angular cheilitis spread to the cheek, the tissues bleed easily and are painful if secondarily infected.

Fig. 38-3: Angular cheilitis seen in patient with riboflavin deficiency.

Management

- Riboflavin 25,000 to 50,000 mcg is given daily in divided doses.

Niacin (vitamin B₃)

It is also known as 'nicotinic acid'. Niacin is required for the formation of coenzyme NAD and NADP, which are important pyridine nucleotides which play an important role in redox reactions involving carbohydrate, protein and lipid metabolism. Deficiency of niacin leads to a disease called as 'pellagra' which means rough skin.

Absorption

It is absorbed from both stomach and intestine and stored in all tissues. It is excreted in the urine mostly as salts and to a smaller extent as free niacin.

Sources

- *Cereals*—rice bran, barley, wheat flour, jowar, wheat germ and finger millet.
- *Pulses and legumes*—peas, soya beans, red gram and split kesari.
- *Vegetables*—turnip greens, beet green, carrot leaves and potatoes.
- *Nuts and oilseeds*—groundnuts, sunflower, almonds and mustard seeds.
- *Fruits*—apricots, passion fruit, custard apple and bael fruit.
- *Animals*—liver of sheep, mutton, beef and prawns.
- *Milk and milk products*—skimmed milk powder, cow's milk and whole milk powder.
- *Tryptophan*—it can be endogenously prepared from tryptophan 60 mg of tryptophan gives 1 mg of niacin.

Daily requirements

- *Infants*—650 mcg per kg body weight daily.
- *Men*—17 mg daily.
- *Women*—13 mg daily.
- *Children*—15 mg daily.
- *Pregnancy and lactation*—12-15 mg daily.

Function in the body

- *Nervous system*—it is important for proper blood circulation and healthy functioning of the nervous system.
- *Gastrointestinal tract*—it is essential for the proper metabolism of proteins and carbohydrates.
- *Blood vessels*—it dilates the blood vessels and increases the flow of blood to the peripheral capillary system.
- *Hormone*—it is essential for the synthesis of sex hormone, estrogen, progesterone and testosterone as well as cortisone, thyroxine and insulin.
- *Others*—it helps to maintain a normal healthy skin.

Pellagra**Causes of deficiency**

- *Tryptophan deficiency*—if insufficient tryptophan is available for synthesis of niacin.
- *Diet*—dietary deficiency of niacin. High dietary levels of amino acid leucine antagonise the synthesis of NAD and NADP.
- *Miscellaneous*—chronic alcoholism, diarrhea and carcinoid syndrome.

Clinical Features

- *Prodromal symptoms*—it can be developed in 3 weeks with prodromal symptoms of loss of appetite, vague gastrointestinal disturbances and numbness or burning in various locations.
- *3 Ds of disease*—it is called as disease of 3-Ds
 - Dermatitis

- Diarrhea
- Dementia
- *Dermatitis*—there is an erythema resembling severe sunburns appears symmetrically over all parts of the body exposed to sunlight and especially on the neck. Affected area is well demarcated from the normal. In acute cases, skin lesions may produce vesiculation, cracking, exudation, crusting with ulceration and secondary infection. In chronic cases, dermatitis occurs as roughening and thickening of skin with brown pigmentation (**Fig. 38-4**).
- *Alimentary tract*—anorexia, nausea, dysphagia. Glossitis precedes the skin lesions. Non infective inflammation may extend through the gastrointestinal tract. Diarrhea is caused by atrophy of gastric epithelium followed by submucosal inflammation which is then followed by ulceration.
- *Nervous system*—delirium is the most common mental disturbance in the acute form and dementia in chronic cases.
- *Others*—there is also loss of appetite, irritability and burning sensation in different areas of the body.

Fig. 38-4: Thickening of skin with brown pigmentation seen in pellagra (Courtesy Dr Pincha).

Oral manifestations

- *Oral mucosa*—entire oral mucosa becomes fiery red and painful and salivation is profuse.
- *Glossitis*—the epithelium of the entire tongue is desquamated. The filiform papillae are most sensitive and disappear first; the fungiform papillae may become enlarged. The tongue becomes red swollen and beefy and in animals the deficiency leads to black tongue. In early stages, only the tip and margins of the tongue are swollen and red. In advanced cases, the tongue loses all the papillae and the reddening becomes intense. In this stage, the tongue becomes so swollen that indentation from the teeth are found along the borders of the tongue.

- *Stomatitis*—the mouth is sore and shows angular stomatitis, cheilitis. Tenderness, pain and ulceration begin at the interdental papillae and spreads rapidly.
- *Other features*—superimposed ANUG or Vincent's infection involving the gingiva, tongue and mucosa is common.

Management

- Niacin 10 mg or 10,000 mcg per day and vitamin B complex should also be given.
- Alcohol should be stopped.

Pantothenic Acid (vitamin B₅)

It is water soluble vitamin of the B complex group. It was discovered by Roger Williams in 1933. Tissue extracts from a variety of biological materials provided a growth factor for yeast. This growth factor is identified as pantothenic acid, derived from Greek word '*pantos*' meaning everywhere. It is a pale yellow oily liquid which is not crystallized, but its calcium crystallizes readily and this is the form in which it is generally available.

Absorption and excretion

It is not destroyed in neutral solution. It is liable to destruction by food, processing techniques, caffeine, sulphur drugs, sleeping pills and alcohol. It is absorbed from the alimentary tract and excreted in urine and mother's milk.

Sources

- *Cereals*—oatmeal, toasted wheat germ, brown rice and wheat flour.
- *Pulses and legumes*—Soya bean flour, split peas, lentil and blackeye peas.
- *Vegetables*—mushrooms, broccoli and cauliflower.
- *Nuts and oilseed*—peanuts, sunflower seeds and cashew nuts.
- *Meat*—calf liver.

Daily requirement

- *Men*—10 mg
- *Women*—10 mg
- *Children*—5.5 mg

Function in the body

- *Metabolism*—it is a part of enzyme system which plays a vital role in the metabolism of carbohydrates, fats and protein and in the synthesis of amino acids and fatty acids.
- *Formation porphyrins*—it is also essential for the formation of porphyrins, the pigment portion of the hemoglobin molecule.
- *Stimulation of gland*—it stimulates the adrenal glands and increases production of cortisone and other adrenal hormones.

- *Anti-stress factors*—it is primarily used as an anti-stress factor and protects against most physical and mental stress.
- *Recovery*—it increases vitality, wards off infections and speeds recovery from ill health.
- *Maintenance of normal growth*—it helps in maintaining the normal growth and development of the central nervous system.
- *Anti aging factor*—it prevents premature ageing and provides protection against any damage caused by excessive radiation.

Deficiency symptoms

- *Muscle tissue*—chronic fatigue, muscle cramps, painful and burning feet and muscular weakness.
- *Nervous system*—mental depression, irritability, dizziness and insomnia.
- *Gastrointestinal*—it may lead to gastric distress and constipation.
- *Others*—increase in tendency toward infection, graying and loss of hair, skin disorders, low blood sugar, low blood pressure and duodenal ulcer.

Management

- It is given in the dose of 1000 mg daily for 6 weeks.

Pyridoxine (Vitamin B₆)

It is an important coenzyme in the intermedullary metabolism of amino acids and complex glycolipids. It is a white crystalline substance soluble in water and alcohol.

Absorption and excretion

It is absorbed mainly in the jejunum and ileum of the small intestine by passive diffusion. It is widely distributed in various tissues and excreted mainly from the kidney. Small quantities of vitamins are excreted in the feces and in sweat.

Dietary sources (Fig. 38-5)

- *Cereals*—wheat germ, brown rice, wheat flour and barley.

Fig. 38-5: Sources of vitamin B₆.

- *Pulses and legumes*—soya beans, lentil and lima beans.
- *Vegetables*—spinach, Brussels sprouts, potatoes and cauliflower.
- *Nuts and oilseeds*—sunflower seeds, walnuts and chestnuts.
- *Fruits*—bananas, avocados, prunes and raisins.

Daily requirements

- *Adults*—2 mg.
- *Children*—1.7 mg.
- *Infants*—0.1–0.4 mg.

Deficiency symptoms

- *Nervous*—peripheral neuropathy, mental retardation, irritability, mental confusion and nervousness.
- *Blood*—anemia, albuminuria and leukopenia.
- *Skin*—dermatitis and eczema.
- *Others*—kidney stones, inflammation of the colon, damage to the pancreas, loss of muscular control, migraine headache and premature senility.

Oral manifestation

- *Cheilosis*—cracking at the corner of the lip.
- *Glossitis*—inflammation of the tongue.
- *Others*—angular stomatitis, tooth decay and halitosis.

Management

- 10–50 mg daily in divided doses.

Biotin (vitamin B₇)

It functions as a coenzyme for four carbohydrates involved in fatty acid and amino acid metabolism. Previously was known as 'vitamin H'.

Daily requirements

- *Men and women*—100–200 mcg.
- *Children*—50–200 mcg.
- *Infants*—35 mcg.

Sources

- *Cereals*—rice bran, rice polishing, rice germ, barley, oatmeal and brown rice.
- *Pulses and legumes*—Soya bean flour, Soya bean, blackeye peas, spilt peas and lentil.
- *Vegetables*—mushrooms and cauliflower.
- *Nuts*—walnuts, peanuts and almonds.
- *Meat*—beef liver.

Function in the body

- *Metabolism*—it is involved in the metabolism of carbohydrates, proteins and fats.
- *Hair*—it is essential for the growth and health of the hair. It prevents premature graying of the hair as well as hair loss.
- *Others*—it helps to maintain the skin and nervous system in a sound condition. It controls proper distribution of color pigments.

Deficiency symptoms

- *Skin*—scaly dermatitis, eczema, seborrhea and prickling of the skin.
- *Hair*—it can cause alopecia and dandruff.
- *Nervous*—there is confusion, mental depression and drowsiness.
- *Muscle*—there is muscular weakness, extreme fatigue and lassitude.
- *Others*—anemia, lack of appetite, hearing abnormalities and lung infections.
- *Oral*—the fleshy part of the tongue may waste away.

Management

- 20 mcg of biotin is taken daily for 10 days IM can heal skin lesions. Oral biotin to be taken in amount of 400 mcg daily for 8–12 weeks. Shampoo coating 1% biotin can be useful in controlling excessive hair loss.

Folic Acid (vitamin B₉)

It is also known as 'folacin' or 'folate'. It is a water-soluble vitamin. It is a yellow crystalline substance sparingly soluble in water and soluble in acid solution. It undergoes fairly rapid destruction when heated in neutral or alkaline substances.

Absorption and excretion

It is absorbed along the entire length of the intestine, although the jejunum of the small intestine is the primary site for its absorption. About half of the folic acid stored in the body is in the liver. A small amount is excreted in the feces and urine but the additional amount is presumed to be metabolized and lost by cells coming off in the form of scales, from the body surface.

Daily requirements

- *Men and women*—100 mcg.
- *Children*—80 mcg
- *Infants*—25 mcg.
- *Pregnant women*—400 mcg.
- *Lactating women*—150 mcg.

Dietary sources

- *Cereals*—bajra, jowar, maize and wheat flour.
- *Pulses and legumes*—cowpeas, whole Bengal gram, split Bengal gram, split green gram, split black gram and lentil.
- *Vegetables*—spinach, cluster beans, ladies finger, curry leaves and French beans.
- *Nuts and oilseeds*—gingelly seeds, groundnuts and coconuts.
- *Meat and poultry*—eggs, liver of sheep and liver of goat.

Functions in the body

- *RBC*—folic acid in combination with vitamin B₁₂ is essential for the formation, maturation and multiplication of red blood cells.

- **Nerve**—it is necessary for the growth and division of all body cells, including nerve cells and for manufacturing a number of nerve transmitters.
- **Hair and skin**—it is essential for the health of skin and hair and helps to prevent premature graying of hair.
- **Pregnancy**—it is an important nutrient for the pregnant women and her developing fetus. Folic acid also improves lactation.
- **Others**—it helps in building of antibodies which prevent and heals infection. It also produces nucleic acids, RNA and DNA.

Deficiency causes

- **Decreased intake**—inadequate diet, impaired absorption, malabsorption states and intrinsic intestinal diseases.
- **Increased loss**—hemodialysis.
- **Increased requirement**—the body demands exceed the intake like in pregnancy, infancy, leukemia, hemolytic anemia.
- **Others**—impaired utilization, diseases of the upper small bowel where folate is mainly absorbed and idiopathic.

Clinical features

- **Anemia**—deficiency of folic acid cause anemia which often occurs in pregnant women and also children.
- **Skin**—loss of hair, grayish brown skin pigmentation can also occurs.
- **Reproductive disorders**—spontaneous abortions, difficulty during labor and high infant death can also occur. Loss of libido occurs in males.
- **Nervous**—dementia, mental depression and fatigue.

Oral manifestations

- **Atrophic glossitis**—filiform papillae disappear first and fungiform papillae remain prominent. In severe cases, fungiform papillae are lost and tongue becomes thick, smooth and fiery red (**Fig. 38-6**).

Fig. 38-6: Atrophic glossitis seen in folic acid deficiency patient.

- **Ulcerative stomatitis**—severe ulcerative stomatitis may be seen.
- **Other features**—swelling and redness of lips and lateral margin of the tongue.

Management

- A daily dose of 5,000 mcg to 10,000 mcg of folic acid is sufficient and a maintenance dose of 5000 mcg once in week is given in cases of megaloblastic anemia.

Cyanocobalamin (vitamin B₁₂)

Vitamin B₁₂ is a complex organomatrix compound called as cobalamine which is cobalt containing porphyrins. It is freely soluble in water. It is resistant to boiling in neutral solution, but it is liable to destruction in the presence of alkalis and acids.

Absorption and excretion

The presence of sufficient quantities of gastric juice is essential to facilitate its absorption in the intestine. Calcium and protein rich foods greatly help in the absorption of this vitamin from the intestine. It is stored in the liver which is capable of storing relatively large amounts of these nutrients. It is excreted in normal urine, stools and breast milk.

Sources (Fig. 38-7)

- **Animal origin**—it is unique amongst vitamins in that it is mostly found in foods of animal origin. Vegetarians are therefore advised to increase their intake of milk or take it in tablet form as a supplement.
- **Fish, meat and poultry**—sheep liver, goat liver, fresh shrimps, yolk eggs, goat meat, mutton, buffalo meat and whole eggs.

Fig. 38-7: Sources of vitamin B₁₂.

- *Milk and milk products*—skimmed milk powder, buffalo milk, cow's milk and curd.

Daily requirements

- *Men and women*—1 mcg.
- *Children*—0.2-1 mcg.
- *Infants*—0.2 mcg.

Functions in the body

- *Red blood cells*—like vitamin B₆ it is essential in the production and regeneration of red blood cells.
- *Nervous*—it improves concentration, memory and balance and relieves irritability.
- *Metabolism*—it is necessary for proper utilization of fats, carbohydrates and proteins for body building. It is also used in metabolism of folic acid.
- *Others*—it promotes growth and increases appetite in children.

Causes of deficiency

- *Congenital*—congenital deficiency without gastric atrophy.
- *Systemic diseases*—diseases of terminal ileum i.e. Crohn's disease.
- *Defective absorption*—there is defective absorption of vitamin B₁₂. There is chronic atrophic gastritis with failure of production of intrinsic factor.
- *Smoking*—studies show that smokers have lower levels of vitamin B₁₂ and folic acid than non-smoker.
- *Others*—inadequate diet and intrinsic factor deficiency.

Deficiency symptoms

- *Megaloblastic anemia*—deficiency of vitamin B₁₂ leads to megaloblastic anemia or pernicious anemia. However, pernicious anemia is a result of deficiency of intrinsic factor, which is essential for absorption of vitamin B₁₂ and hence a deficiency of vitamin B₁₂.
- *Age and sex*—it occurs in 5th to 8th decades of life. It is more common in men than in women.
- *Symptoms*—there is generalized weakness, numbness and tingling of the extremities. Fatigue, headache, dizziness, nausea, vomiting, diarrhea, loss of appetite, pallor and abdominal pain.

Oral manifestations

- *Tongue*—there is sore painful tongue, glossitis and glossodynia. Tongue is inflamed and is beefy red in color. Painful and burning lingual sensation. Small shallow ulcers resembling aphthous ulcers on the tongue with atrophy of papillae with a loss of normal muscle tone is called as 'hunter's glossitis'. Fiery red appearance of tongue due to inflammation and burning sensation.
- *Denture wearing discomfort*—discomfort in wearing dentures is due to weakened muscular tone.

Management

- *Oral*—it is used in a dose ranging from 6 to 150 mcg, helps in the treatment of lack of concentration, fatigue depression, insomnia, anorexia, poor memory and loss of weight.
- *Parenteral*—1000 mcg of vitamin given twice weekly in cases of anemia.

Vitamin C

It is also called as 'ascorbic acid' and 'antibiotic vitamin'. It is a modified simple sugar. It is the most active reducing agent. Its highest concentration is in the pituitary, adenoid, eye and WBCs. Stress and corticotrophin leads to loss of ascorbic acid from the adrenal cortex. It is a powerful antioxidant. It is necessary for normal maintenance of intercellular substances of connective tissue in bone and other tissue of mesenchymal origin.

Absorption and excretion

Absorption of ascorbic acid into the bloodstream takes place in the upper part of the small intestine. It is excreted by the kidney through the urine.

Dietary sources (Fig. 38-8)

- *Cereals, pulses and legumes*—red gram, peas, maize and Bengal gram.
- *Vegetable*—parsley, drumstick leaves, turnip greens, cabbage, bitter gourd, radish leaves, carrot leaves, beet greens cauliflower, cluster beans, tomatoes, spinach and ladies finger.
- *Nuts*—coconut dry and coconut milk.
- *Fruits*—Indian gooseberries, guavas, orange juice, limes, papayas strawberries, lemons, pineapples, custard apple, raspberry and mangoes.
- *Fish and meat*—Indian shad, Rohu, sheep liver and tenger fish.

Fig. 38-8: Sources of vitamin C.

- *Milk and milk product*—khoa and skimmed milk powder and wholemilk powder.

Daily requirements

- *Men and women*—40 mg.
- *Infants*—25 mg.
- *Children*—40 mg.
- *Pregnant and lactating women*—80 mg.

Functions of vitamin C

- *Synthesis*—it is important in the formation of collagen, chondroitin sulfate and neurotransmitter.
- *Maintenance*—it is useful for maintenance of folate pool and mobility and phagocytic activity of neutrophils. It is also necessary for maintenance of bones and proper functioning of the adrenal and thyroid glands.
- *Absorption*—it enhances, the absorption of iron in the body.
- *Metabolism*—tryptophan, nor-epinephrine and tyrosine metabolism require vitamin C.
- *Others*—it promotes healing and protects against all forms of stress.

Deficiency symptoms

- *Mild deficiency*—it may appear in the form of lassitude fatigue, anorexia, muscular pain and greater susceptibility to infection.
- *Severe or prolonged deficiency*—a prolonged deficiency may cause scurvy.

Scurvy

Prolonged deficiency of vitamin C may result in scurvy. It is characterized by weakened blood vessels particularly microvessels having least muscular supports. There is also defective synthesis of osteoid which is derivative of collagen which results in impaired wound healing.

Pathogenesis

- *Defective collagen formation*—there is defective formation of collagen in connective tissues because of failure of hydroxylation of proline to hydroxyproline which is a characteristic amino acid of collagen.
- *Increase capillary permeability*—there is also increase in permeability of capillary (hemorrhage), anemia due to erythropoiesis and defective collagen formation.

Clinical features

- *Infantile scurvy*—lassitude, anorexia, painful limbs and enlargement of costochondral junction.
- *Folliculosis*—hair follicle rises above skin and there are perifollicular hemorrhages i.e. tiny points of bleeding occurring around the orifice of hair follicles with heaping of keratin like material.
- *Hemorrhage*—hemorrhage may occur in the joint, into nerve sheath under the nails or conjunctiva. Petechial hemorrhage occurs in buttocks, abdomen, legs, arms,

ankle and nail beds. There is also epistaxis, anemia and delayed wound healing.

- *Scorbutic child*—scorbutic child usually assumes a 'frog like' position and this may reflect as subperiosteal hemorrhage.
- *Edema*—edema of the limbs and face is a frequent finding in severe ascorbic acid deficiency.
- *Other features*—it may lead to premature aging, thyroid insufficiency and lower resistance to all infections.

Oral manifestations

- *Site*—it occurs chiefly in gingival and periodontal region.
- *Scurvy bud*—interdental and marginal gingiva is bright red, swollen, smooth, shiny surface producing an appearance known as 'scurvy bud' (Fig. 38-9). In fully developed scurvy, the gingiva becomes boggy, ulcerated and bleeds easily.
- *Color*—color changes to violaceous red.
- *Breath*—typical fetid breath of the patient with fusospirochetal stomatitis.
- *Severe cases*—in severe cases, hemorrhage and swelling of periodontal ligament membrane occurs followed by loss of bone and loosening of teeth which are exfoliated.

Fig. 38-9: Scurvy buds seen on gingiva in vitamin C deficiency patient

Diagnosis

- *Clinical diagnosis*—scurvy buds with increased hemorrhagic tendency may give clue to the diagnosis.
- *Laboratory diagnosis*—the calcified matrix material is not destroyed so that wide zone of calcified but nonossified matrix, called the 'scorbutic lattice' develops in the metaphysis. Anemia in scurvy is mild to moderate but may be severe.

Management

- Vitamin C 250 mg 3 times daily can be given.

Choline

It is a colorless crystalline compound which absorbs water quickly. It is highly soluble in water and alcohol. It is member of vitamin B group. It is present in foods as well as in the body in relatively large amount.

The body can make choline from methionine, an amino acid, with the aid of vitamin B₁₂ and folic acid.

Absorption and Excretion

It is highly soluble in water and alcohol. It is absorbed from the intestine and excreted mostly through the urine.

Sources

- *Fish and sea food*—it is available in liberal quantities in fish and sea foods.

Functions

- *Fat transportation*—it helps in the transportation of fats in the body and prevents accumulation of fat in the liver.
- *Nerve cell formation*—in combination with fatty acid and phosphorus, it stimulates the formation of lecithin, an important constituent of nerve cells in the body.
- *Memory*—it goes directly into the brain cells to produce a chemical that aids memory.

Deficiency Symptoms

- It may cause cirrhosis and fatty degeneration of the liver, high blood pressure and atherosclerosis.

Management

- *Doses*—it can be given in doses of 1000-2000 mg daily in divided doses.

Inositol

It is a crystalline compound which has sweet taste. It is highly soluble in water and is not destroyed by heat in neutral, acid and alkaline media.

- *Functions in the body*
 - *Fat transportation*—it is essential for transportation of fat in the body.
 - *Brain cells nourishment*—it is important in providing nourishment to the brain cells.
 - *Maintenance of cholesterol level*—it helps to lower cholesterol levels.
 - *Hair growth*—it also promotes the growth of healthy hair and helps to prevent its falling.
 - *Prevention of eczema*—it helps in preventing eczema.
- *Sources*—the most important sources is from liver, brewer's yeast, wheat germ, unrefined molasses, peanuts and cabbage.
- *Deficiency symptoms*—it can cause alopecia or patchy baldness, gastritis hypertension, fatty infiltration in the liver, hardening of the liver and eczema.
- *Doses*—it is given in the dose of 2 gm a day for 6-10 weeks.

Fat Soluble Vitamins

Common Properties

- They are soluble in fat.
- Bile salts are essential for their absorption.
- They are generally stored in the liver.
- They are not excreted in urine.

Vitamin A (Retinol)

Carotene is a yellow pigment found in vegetable foods. It is converted into vitamin A in the body. Vitamin A or retinol is found in foods of animal origin, while carotene is provided by foods of both plant and animal origin. Vitamin A is stored in liver. As a concentrated solution retinol is light yellow in color. It solidifies when cooled and has a mild pleasant odor.

Absorption

Approximately 80% of vitamin A is absorbed in the human system. It is passed along with fat through the lymphatic system in to the bloodstream. Absorption of vitamin A is increases if it is taken with fats. Absorption more rapid in men than in women. Absorption is of this vitamin is poor in cases of diarrhea, jaundice and abdominal disorders. Vitamin A which is not absorbed is excreted within one or two days in feces.

Sources (Fig. 38-10)

- *Plant sources*
 - *Cereals and pulses*—red gram, soya beans, bajra and lentil.
 - *Vegetables*—carrots, green leafy vegetables and spinach.
 - *Fruits*—sweet potatoes, papayas, tomatoes, mangoes, persimmon and raspberries.
- *Animal sources*—sheep liver, cow's milk, kidneys, fish liver oils.
- *Fats and edible oils*—butter, hydrogenated oil and ghee.

Fig. 38-10: Sources of vitamin A.

Requirements

- *Men and women*—600 mcg
- *Pregnancy and lactation*—950 mcg
- *Children*—600 mcg
- *Infants*—350 mcg

Functions in the Body

- *Epithelial tissue*—vitamin A helps in maintaining the integrity of epithelial tissue such as epithelial layer of skin, respiratory mucosa and esophagus and gastrourinary tract. Due to this, it builds up resistance to respiratory infection.
- *Structural integrity*—its function in the preservation of the structural integrity and normal permeability of the cell membrane as well as that of membrane of intracellular particles such as lysosomes and mitochondria.
- *Bone and teeth*—it accelerates the normal formation of bones and teeth.
- *Vision*—vitamin A also has a specific role on the physiological mechanism of vision.
- *Oxygenation*—it also increases permeability of blood capillaries thereby contributing to better tissue oxygenation.
- *Aging and senility*—it also prevents premature ageing and senility.
- *Synthesis*—it is required for synthesis of glucocorticoids and cholesterol.
- *Somatic growth*—vitamin A is required for somatic growth.

Deficiency Symptoms

- *Effect on growth*—failure of growth in young and collagenous tissue is affected.
- *Effect on eyes*—night blindness, dry conjunctiva, Bitot's spot, corneal xerosis, corneal ulceration or keratomalacia can occur. Xerophthalmia due to decrease in lacrimal secretion.
- *Keratinizing metaplasia*—the epithelial cells fail to differentiate. This means that the cells in the basal layer lose their specificity and tend to form a stratified squamous epithelium with keratin production. Keratinizing metaplasia of epithelial cells is usually evident in several organs such as bladder, vagina and skin and predisposes them to infection. Drying of skin and atrophy of sebaceous glands.
- *Effect on reproductive organs*—degeneration of germinal epithelium thus affecting reproduction causes sterility in males and cornification of vaginal epithelium in females.
- *Effects on bone*—imbalance between osteoblasts (bone forming cells) and osteoclasts (bone resorbing cells) causing aberrations in the shape of bone.

- *Skin disorders*—it may result in pimples, acne, boils and premature wrinkles.

Oral Manifestations

- *Teeth*—defective formation of enamel in teeth. Odontogenic epithelium fails to undergo normal histodifferentiation and morphodifferentiation, which results in increased rate of cell proliferation. Therefore epithelial invasion of pulpal tissue is characteristic of vitamin A deficiency. There is also distortion of shapes of the incisors and the molars.
- *Hypoplasia of teeth*—since the enamel forming cells are disturbed, enamel matrix is poorly defined so that calcification is disturbed and enamel hypoplasia results (Fig. 38-11).

Fig. 38-11: Enamel hypoplasia seen in patient with vitamin A deficiency.

- *Dentin*—dentin is too atypical in structure, lacking the normal tubular arrangement and containing vascular and cellular inclusions.
- *Caries*—there is increased caries susceptibility.
- *Eruption*—eruption is delayed. In prolonged deficiency, eruption ceases completely.
- *Alveolar bone*—alveolar bone is retarded in its rate of formation.
- *Gingiva*—gingival epithelium becomes hyperplastic; in prolonged deficiency it shows keratinization.
- *Periodontal disease*—tissue is easily invaded by bacteria that may cause periodontal disease and micro abscess formation.
- *Salivary gland*—major and minor salivary glands undergo typical keratinizing metaplasia.

Management

- Depending upon deficiency symptoms it is given in the dose of 7500-15,000 mcg per day for one month.

Hypervitaminosis A

- *Causes*—if more than 30,000 mcg of vitamin A is taken daily, it can produce toxic effect in adults if continued

for many months. In infants, toxic effect can be produced by the intake of more than 5,550 mcg per day.

- *Toxicity symptoms*—painful joints, thickening of long bones, anorexia, low grade fever, loss of hair, hepatomegaly, blurred vision, rashes, irregular menstruation, fatigue and headache.
- *Acute toxicity*—it results from a single massive dose and it manifests as abdominal pain, nausea, vomiting, headache, dizziness and sluggishness.
- *Chronic toxicity*—it may occur following ingestion of 12,000 mcg or more daily for prolonged periods. It is characterized by joint pain, hair loss, dryness and fissuring of lips, loss of appetite, low grade fever and weight loss.
- *Radiological findings*—radiographically, there is fragmentation of the distal fibular epiphysis and pronounced periosteal thickening.

Carotenemia

There is generalized yellowish skin and mucosa seen in patient. There is also excessive deposition of carotene which is result of high intake of foods containing carotene. Increased yellowishness is also seen in hyperlipidemia, diabetes, nephritis and hypothyroidism and in condition in which conversion of carotene to vitamin A is impaired by inborn metabolic error or hepatic disease.

Management

- *Restriction of diet*—there should be restriction of diet in the patients.

Vitamin D

It is also called as 'sunshine vitamin'. Vitamin D (1,25-dihydroxycholecalciferol) is one of the compound that are grouped together as the hydroxylated cholecalciferol. If vitamin D deficiency occurs in children and infants it is called as 'rickets' and if it occurs in adults it is called as 'osteomalacia'. Deficiency of vitamin D tends to cause hypocalcemia.

Forms

- D_3 —it is present in fish liver oils and animal fats. It is called as cholecalciferol.
- D_2 —it is obtained artificially by irradiation of ergosterol and called as ergocalciferol.

Absorption

Bile is essential for the absorption of vitamin D, fat helps in its absorption too. The vitamin is absorbed from the jejunum of the small intestine and is transported in the lymph chylomicrons to the bloodstream. Excretion of vitamin D

and its metabolites occurs primarily in the feces with the aid of bile salts.

Function in the Body

- *Maintenance*—the major function of vitamin D is the maintenance of normal plasma levels of calcium and phosphorous.
- *Teeth and bone*—it is very important for the proper formation of teeth and bones. It plays an important role in prevention of dental caries.
- *Thyroid gland*—it is necessary for the healthy functioning of parathyroid gland, which regulates the calcium levels in the blood.

Requirement

- *Infants and children*—0.01 mg.
- *Men and women*—0.01 mg.
- *Pregnancy and lactating women*—0.01 mg.

Sources (Fig. 38-12)

- *Fish and poultry*—cod liver oil, shark liver oil and eggs.
- *Fats and edible oils*—ghee and butter.
- *Sunlight*—it is the most important source the vitamin D.

Fig. 38-12: Sources of vitamin D.

Pathogenesis

- *Overgrowth*—there is overgrowth of epiphyseal cartilage due to inadequate provisional calcification and failure of cartilage cells to form a matrix and disintegrates.
- *Formation of irregular masses*—there is persistence of distorted, irregular masses of cartilage many of which projects into the marrow cavity.
- *Deposition*—deposition of osteoid matrix on inadequately mineralized cartilaginous remnants.

- *Disruption*—disruption of the orderly replacement of cartilage by osteoid matrix with enlargement and lateral expansion of osteochondral junctions.
- *Microfracture*—there is abnormal growth of capillaries and fibroblasts in the disorganized zone because of microfracture and stresses on inadequately mineralized, weak, poorly formed bone.
- *Deformity*—deforming of skeleton due to loss of structural rigidity of the developing bone.

Vitamin D Deficient Rickets

The word 'Rickets' refers to any disorder in vitamin D calcium phosphorous axis which results in hypomineralized bone matrix that is failure of endochondral calcification. It develops in an area where sunlight is deficient. It results from inadequate extracellular level of calcium and inorganic phosphate, mineral necessary for new bone to calcify. Osteoid builds in excessive amounts because it fails to mineralize properly. Rickets occur in infants and children and osteomalacia common in adults.

Clinical features

- *Age*—it occurs in infants and children. In the first 6 month of life, tetany, convulsions are common manifestations due to hypocalcemia.
- *Sites*—the wrist and ankles are typically swollen. The changes in bone are found in the epiphyseal plates, metaphysis and the shaft.
- *Craniotabes*—localized area of thinning are sometimes present in the skull, so that a finger can produce indentation. This condition is called as 'craniotabes'. There is softening of posterior part of the parietal bone, which may be first sign of the disease.
- *Extremities*—patients has a short stature and deformed extremities. Children with rickets show bowing of legs.
- *Head*—excess of osteoid produces frontal bossing and squared appearance to the head.
- *Rachitic rosary*—deformation of chest results from over growth cartilage or osteoid tissue at the costochondrial junction producing 'rachitic rosary'.
- *Pigeon breast*—the weakened metaphyseal areas of the ribs are subject to pull of the respiratory muscles and thus bend inwards creating anterior protrusion of the sternum resulting in a pigeon breast deformity.
- *Harrison grooves*—the inward pull at the margins of diaphragm creates Harrison's grooves, girdling the thoracic cavity at the lower margin of the rib cage.
- *Lumbar lordosis*—the pelvis may be deformed. When an ambulatory child develops rickets, deformities are likely to affect the spine, pelvis and long bones causing 'lumbar lordosis'.

Oral manifestations

- *Teeth*—developmental abnormalities of dentine and enamel, delayed eruption and malalignment of teeth.
- *Caries*—there is higher caries index in rickets as compared to normal.
- *Enamel*—there may be hypoplasia of enamel; enamel may be mottled, yellow gray in color.
- *Pulp*—there are large pulp chamber, high pulp horns and delayed closure of root apices.
- *Malocclusion*—the osteoid is so soft that teeth are displaced leading to malocclusion of the teeth.

Radiographic features

- *Long bones*—the earliest and prominent manifestation is widening and fraying of epiphysis of the long bones. Bowing is a characteristic deformity seen in the weight bearing areas, fine trabeculae are reduced in number.
- *Green stick fractures*—it will be noted in many cases.
- *Jaw bone*—a thinning of jaw cortical structure such as the inferior mandibular canal, the lamina dura and the follicular walls of developing teeth has been described in rickets. The trabeculae become reduced in number. In severe cases, jaws appear completely radiolucent, so that teeth appear to be suspended in air.
- *Teeth*—if the disease occurs before 3 years of age, enamel hypoplasia is fairly common. The pulp cavities of deciduous teeth are grossly enlarged. The dentin is reduced to a thin margin separating the pulp cavity from enamel and cementum. The density of existing dentin appears to be normal and margins of pulp cavities are well and sharply defined. There is narrowing of the periodontal ligament space.

Diagnosis

- *Clinical diagnosis*—rachitic rosary, pigeon breast, Harrison grove with hypocalcification will diagnosed rickets.
- *Radiological features*—green stick fracture with narrowing of periodontal space.

Management

- *Dietary enrichment*—dietary enrichment of vitamin D in the form of milk.
- *Calcium gluconate*—if tetany is present, give calcium gluconate IV. Daily dose between 1000-2000 IU of vitamin D combined with 500-1000 mg of calcium. Curative treatment includes 2000 to 4000 IU of calcium daily for 6 to 12 weeks followed by a daily maintenance dose of 2000 to 4000 IU for a prolonged period.
- *Hormonal therapy*—hormonal therapy like flucytosine.

Vitamin D Resistant Rickets (Familial Hypophosphatemia, Refractory Rickets)

It is X-linked trait with some defect in reabsorption or metabolism.

Pathogenesis

- Vitamin D promotes the absorption of calcium and phosphorus from the intestinal tract, therefore diet deficient in vitamin D produces a negative calcium balance that in turn leads to under mineralization of the skeletal system. Thus rickets is caused by a lack of calcification of cartilage and osteoid tissue.

Causes

- *Decreased renal tubular reabsorption*—the disease is now recognized as a specific disorder characterized by hypophosphatemia associated with decreased renal tubular reabsorption of inorganic phosphates.
- *Genetic*—familial occurrence being inherited as X linked dominant trait.
- *Diminished calcium and phosphate absorption*—diminished intestinal calcium and phosphate absorption.

Clinical features

- *Age*—it is first recognized in children when they are about to walk.
- *Stature*—slight decrease in height of the patient and reduced growth and rickets like bone changes.
- *Signs and symptoms*—bowing of legs, enlarged epiphysis, bone pain, muscle weakness and vertebral fracture. Bony outgrowth at the site of muscular attachment and around joints may limit the movement

Oral manifestations

- *Dentin*—widespread formation of globular hypocalcified dentin with clefts and tubular defects occurring in the region of pulp horns. Gross reduction in amount and quantity of dentin which results in abnormally wide root canal and large pulp chambers with faulty calcification and marked interglobular space in dentin.
- *Pulp*—pulp horns are elongated and extend high often reaching the dentoenamel junction.
- *Periapical infection*—because of this defect there commonly is invasion of the pulp by microorganisms without demonstrable destruction of the tubular matrix. Thus there is often periapical involvement of a grossly normal appearing deciduous or permanent tooth followed by the development of multiple gingival fistulae. Tract is frequently present in dentinoenamel junction or even outer enamel surface. This tract remains patent and may result in early pulpal infection developing in abscess or carious lesion.
- *Cementum*—there is formation of abnormal cementum.

Radiographic features

- *Lamina dura*—lamina dura around the teeth is frequently absent or poorly defined. Osteoporotic bone with thinned dental crypts.
- *Jaw bones*—in some cases, only a relatively faint outline of the jaw is seen, with almost complete absence of

trabeculation. In such cases, there is no evidence of the normal cortical layer of bone around the follicle of developing teeth; as a result they appear unsupported by solid tissue.

- *Long bone*—it shows persistent deformities fracture and pseudo fractures.
- *Teeth*—thin enamel cap and enlarged pulp chambers and root canals. The dentin is reduced to a thin margin separating the pulp cavity from the enamel and cementum.
- *Infection*—high incidence of periapical and periodontal abscess which spread diffusely through the bone. The reasons for this is that as enlarged pulp forms in these teeth reaching nearly to dentinoenamel junction and there may be invasion of microorganisms in areas of hypoplastic enamel leading to pulpal necrosis. Alveolar pattern of bone is abnormal.

Diagnosis

- *Clinical diagnosis*—similar clinical feature of vitamin D dependent rickets with absence of teeth hypocalcification.
- *Radiological features*—multiple periapical infection with loss of lamina dura.
- *Laboratory diagnosis*—biopsy shows deposition of bone salts in cartilage matrix between the rows of hypertrophic cells so that these cells are not invaded and destroyed by capillaries. The histological feature is characterized by a broad zone between the multiplying cartilage cells and the shaft the so called 'rachitic metaphysis' which is composed of tongues of cartilage which extend down toward the shaft and are separated from one another by collection of capillaries.

Management

- *25-hydroxy cholecalciferol*—it is given lower doses is useful than conventional vitamin D.
- *Calcitrol and phosphate*—multiple daily doses of phosphate and calcitrol are given.
- *Endodontic therapy*—it is done tooth with periapical pathology.

Osteomalacia

It is also known as 'adult rickets' and only flat bones and diaphyses of long bones are affected. It is most commonly seen in post menopause females with a history of low dietary calcium intake and little exposure to UV light.

Clinical features

- *Age and sex*—it is seen in adults and pelvic deformities are commonly seen in females.
- *Bone*—remodeling of bone occurs in the absence of adequate calcium resulting in softening and distortion of the skeleton.

- *Symptoms*—the majority of patients has bone pain and muscle weakness of varying severity.
- *Others*—there is increased tendency towards fracture, peculiar waddling or penguin gait, tetany and green stick bone fractures.

Oral manifestations

- *Severe periodontitis*—there is incidence of severe periodontitis in some cases of osteomalacia.

Radiographic features

- *Pseudofracture*—a poorly calcified ribbon like zone extending into bone at approximately right angles to the periosteal margin. They are partial or complete fracture without displacement in which callus has been formed but there is no calcium available to be deposited, thus healing process is not complete and fracture remains apparent radiographically. It is also called as “Looser’s zone”. Osteoid tissue is formed in the defect but there is no calcium available to be deposited in the osteoid.
- *Jaws*—pseudofracture of the jaws near the angle has also been noted.
- *Bone*—individual bony trabeculae may be sparse and unusually coarse in intraoral periapical radiograph.
- *Lamina dura*—the lamina dura may be thin or absent in long standing and severe cases of osteomalacia.

Diagnosis

- *Clinical diagnosis*—bone pain, muscle weakness, fracture and waddling gait.
- *Radiological diagnosis*—pseudofracture can be seen radiologically.
- *Laboratory diagnosis*—there is elevation of serum alkaline phosphatase to three or more times its normal levels. Serum phosphorus is low due to increased phosphorus excretion in response to reduction of serum calcium. Serum calcium levels are usually on the lower side.

Management

- *Doses*—patients with osteomalacia due to intestinal malabsorption require a larger dose of vitamin D and calcium i.e. 40,000 to 1, 00,000 IU of vitamin D and 15 to 20 gm of calcium lactate per day.
- *Effect of hypervitaminosis D*—if patient is given in excess of vitamin D, patient may suffer from nausea, vomiting, constipation, drowsiness and sign of renal failure. There is also metastatic calcification in arteriole and kidneys and other tissues.

Vitamin E (Tocopherol)

It is also called as ‘anti-aging’ factor. The word tocopherol is derived from the word *tocos* meaning child birth and *pheros* meaning to bear. It is yellow, oily liquid freely soluble in fat solvents. Tocopherol alpha, beta, gamma, lambda

have been obtained from natural sources and their relationship with fertility and prevention of muscular dystrophy have been found. They are not destroyed by heat even at room temperature or above 100°C. They are destroyed by UV light.

Absorption and Excretion

Vitamin E in the diet is absorbed from the gastrointestinal tract by a mechanism similar to that for other fat soluble vitamin. It enters the bloodstream via the lymph. About 1/3rd of the vitamin is excreted in the bile and the balance is excreted in the urine.

Sources (Fig. 38-13)

- *Vegetables oils*—the richest sources of vitamin E are cold pressed crude vegetable oils, especially wheat germ, sunflower seeds, safflower and soya bean oils.
- *Cereals*—raw sprouted seeds and grains especially whole wheat are moderate sources.
- *Animal*—meats, eggs are minor sources of vitamin E.

Fig. 38-13: Sources of vitamin E.

Daily Requirements

- *Men*—15 mg.
- *Women*—12 mg.
- *Children*—8.3 mg
- *Infants*—4-5 mg.

Functions in the Body

- *Reproductive function*—protective effect of vitamin E on reproduction and prevention of sterility. All the three layers of embryo ectoderm, mesoderm and endoderm are preserved by vitamin E.
- *Blood flow and clotting mechanism*—vitamin E dilates the capillary and enables the blood to flow freely into the

blood deficient muscle tissue thus strengthening both the tissue and the nerves supplying them. It also dissolves the blood clot and also prevents their formation.

- *Electron transport system*—it functions as a cofactor in the electron transport system.
- *Healing*—it prevents the formation of excessive scar tissue and in some instance, even melts away unwanted scar tissue.
- *Prevention*—it is required for prevention and storage of creatinine in muscles. It has ability to prevent hepatic necrosis in animals. Prevents vitamin A from destruction and helps in its storage in tissue.

Deficiency Symptoms

- *Reproductive*—abortion of fetus in females and atrophy of spermatogenic structures in males leading to permanent sterility.
- *Muscles*—it causes degenerative changes in muscles. There is muscle fiber atrophy which is replaced by connective tissue.
- *Heart*—there is necrosis and fibrosis of heart muscles.
- *Blood capillaries*—deficiency may lead to degenerative changes in the blood capillaries which in turn lead to heart and lung diseases, pulmonary embolism and brain stroke.

Oral Manifestations

- Loss of pigmentation, atrophic degenerative changes in enamel of vitamin E deficient rates.

Management

- Vitamin E is given in the doses of 100 -400 mg daily.

Vitamin K (Phylloquinone)

It is essential for the production of a type of protein called Prothrombin and other factors involve in the blood clotting mechanism. Hence it is known as '*anti-hemorrhagic vitamin*'. It is not easily destroyed by light, heat or exposure to air. It is destroyed by strong, acids, alkalis and oxidizing agents.

Forms

- K_1 —it is the form which occurs in plants.
- K_2 —it is produced by most bacteria present in human intestine if not supplied in the diet.

Requirements

- *Men and women*—70-140 mcg.
- *Children*—35-75 mcg.

Sources (Fig. 38-14)

- *Vegetables*—kale, turnip greens, spinach, broccoli, cabbage, lettuce, asparagus and watercress.

Fig. 38-14: Sources of vitamin K.

Functions in the Body

- *Synthesis*—it is essential for the hepatic synthesis of coagulation factors II, V, VII, IX and X.
- *Clotting*—it prevents hemorrhage only in cases when there is defective production of prothrombin.
- *Oxidative phosphorylation*—it acts as a cofactor in oxidative phosphorylation associated with lipid.

Effects of Deficiency

- Prolongation of clotting time and a tendency to bleed profusely.
- There may be nasal bleeding.

Oral Manifestations

- Gingival bleeding can also occur in cases of vitamin K deficiency.

Management

- It is given in dose of 10-20 mg daily.

Introduction

Man is a complex biologic unit in a complex environment. Duncan defined metabolisms as sum of total tissue activity as considered in terms of physicochemical changes associated with and regulated by availability, utilization and disposal of protein, fat, carbohydrate, vitamins, minerals, water and influence which the endocrine exerts on these processes. Alternation from this normal metabolic process constitutes the disturbances of metabolism.

Disturbances in Protein Metabolism

All living tissues, whether plant or animal contains protein. Proteins constitute the most important group of foodstuffs. In addition to contributing to cells and intercellular materials, proteins and their constituent amino acids are important in the formation of hormone, enzymes, plasma proteins, antibodies and numerous other physiologically active substances. 1 gm of protein is required for each kg of body weight. It is required in increased quantity in later half of pregnancy, during lactation and infancy, childhood and adolescence.

Protein Energy Malnutrition

Protein energy malnutrition is characterized by energy deficit in macronutrient and micronutrient. Protein is the most important group of foodstuff. In addition to contributing to cells and intercellular material, proteins also help in the formation of hormones, enzymes, plasma protein antibodies and numerous physiologically important substances.

Types

- *Marasmus*—it is an overall deficit of food intake which results from near starvation with deficiency of protein and non-protein nutrient.
- *Kwashiorkor*—it is associated with primary dietary protein deficiency.
- *Marasmic kwashiorkor*—this is combined form of between the two extremes.

Etiology

- *Prolonged illness*—it occurs due to prolonged febrile illness, massive burns and large chronic ulcer.
- *Chronic infection*—chronic infections like urinary tract infection, tuberculosis and parasitic infection.
- *Endocrine disease*—hyperthyroidism and hyper-metabolic state which interfere with utilization.
- *Other*—stress, starvation and persistent vomiting and diarrhea.

Clinical Features

- *Age*—it occurs between the age of 1 and 3 years in children.
- *Marasmus*—there is emaciation due to weight loss, wasting of subcutaneous fat and muscles. Marasmus can also cause infantile gastroenteritis.
- *Kwashiorkor disease*—there is generalized edema, flaky paint dermatosis, thinning, and reddening of hair. There is also enlarged fatty liver. Kwashiorkor is distinguished from Marasmus by the presence of edema and the relatively less severe degree of body wasting.
- *Striped flag appearance*—alternating episodes of under nutrition and adequate nutrition may cause hair to have dramatic striped flag appearance. This is seen in kwashiorkor disease.

Oral Manifestations

- *Tongue*—bright reddening of tongue with loss of papillae. In kwashiorkor patient may have edema of tongue and may develop scalloping around the lateral margins due to indentation of the teeth. Papillary atrophy may be present and dorsum of the tongue assumes an erythematous and smooth appearance.
- *Perioral finding*—there is bilateral angular cheilosis, fissuring of lip. Loss of circumoral pigmentation.
- *Xerostomia*—mouth becomes dry. However, there is reduced caries activity due to lack of substrate carbohydrate.
- *Epithelium*—epithelium easily becomes detached from underlying tissue, leaving raw bleeding surface.
- *Jaws*—decreased overall growth of jaws, delayed eruption, retarded growth of incisors and molars.
- *Periodontal membrane*—The gingiva and periodontal ligament membrane exhibit varying degrees of degeneration.
- *Teeth*—deciduous teeth of children exhibits linear hypoplasia of the teeth.
- *Maxillofacial gangrene*—is severe infection that spread in mouth from necrotizing gingivitis.

Diagnosis

- *Clinical diagnosis*—striped flag appearance, weight loss, wasting of muscle, and flaky paint will give clue to diagnosis.
- *Laboratory diagnosis*—it may cause mild anemia which is normocytic and normochromic. The reticulocyte count is normal and the bone marrow tends to become hypocellular.

Management

- *Antibiotics*—infection should be treated with antibiotics.
- *Nutritional supplement*—it is usually supplied with milk based formulae. Full fat desiccated milk products can be fortified with corn oil and maltodextrin.

Amyloidosis

It is also called as 'amyloid disease'. It is deposition of amyloid in the tissue.

Forms of Amyloid

- *Type A* (secondary) amyloid is a fibrillar protein of unknown origin that is seen in prolonged inflammatory disease, genetic disease and syndromes such as familial Mediterranean fever.
- *Type B* (primary) amyloid is thought to be immunologic in origin because of its sequence homology with the NH₂

terminal end of immunoglobulin light chain. It is commonly seen in patient with multiple myeloma and macroglobulinemia.

- *Type C*—it includes amyloid of aging, localized nonspecific amyloid and pheochromocytomas.

Types

- *Primary amyloidosis*—there is no evidence of preceding or existing disease.
- *Amyloidosis associated with multiple myeloma*—it usually affects adult patients.
- *Secondary amyloidosis*—associated with variety of chronic inflammatory disease.
- *Localized amyloidosis*—it is characterized by small localized deposits of amyloid in the skin, bladder and respiratory tract.
- *Familial amyloidosis*—it is rare condition such as familial Mediterranean form or familial amyloidosis with polyneuropathy.
- *Hormone related amyloid*—it is associated with tumors of endocrine cells which secretes peptide hormones.

Etiology

- *Collagen diseases*—like rheumatoid arthritis.
- *Chronic infection*—chronic infections like tuberculosis, osteomyelitis, regional enteritis and ulcerative colitis.
- *Malignant disease*—malignant diseases like multiple myeloma, Hodgkin's lymphoma and renal cell carcinoma.

Clinical Features

- *Site*—commonly affected organs are kidneys, heart, G.I. tract, liver, respiratory tract, skin, eyes, adrenals, nerves and spleen. There may be primary localized collection of amyloid.
- *Symptoms*—the general symptoms are fatigue, weakness, ankle edema, dyspnea, paresthesia, orthostatic hypotension and weight loss.
- *Signs*—purpuric spots caused by hemorrhage resulting in formation of amyloid deposits in the blood vessels. Superficial waxy lesion occurs on the eyelids, nasolabial folds, neck, axilla or perineum and they may bleed on pressure.
- *Myocardium*—congestive cardiac failure is a common problem due to amyloid deposits in myocardium.
- *GIT involvement*—there is hepatomegaly, malabsorption or colitis may develop.

Oral Manifestations

- *Symptoms*—there are difficulties in chewing, swallowing or talking. The speech difficulty is due to paresis of the

vocal cord resulting from deposit of amyloid in the upper third of larynx.

- *Appearance*—tongue is enlarged and studded with small garnet colored enlargements along with nodes of cheeks and lips.
- *Signs*—mobility of the tongue is decreased. Yellowish nodules are present along the lateral border of the tongue and impressions from the teeth are also visible.
- *Skin lesion*—it may diffusely involve the face or may present as small elevated yellow nodules.
- *Macroglossia*—fibrous glycoproteins are deposited in submucosa as well as in deeper muscular layer of tongue. Amyloid deposition of tongue is found resulting in macroglossia of tongue. It is seen in both primary and secondary form.
- *Gingiva*—the gingiva may be infiltrated and may be bluish, spongy and hypertrophied.
- *Salivary gland involvement*—xerostomia may result from salivary gland involvement.

Diagnosis

- *Clinical diagnosis*—macroglossia with amyloid deposits can be seen on the face of patient.
- *Scintiscanning*—scintiscanning with ^{99m}Tc to localized soft tissue deposits.
- *Laboratory diagnosis*—congo red is used to diagnose amyloid which shows birefringence and dichroism.

Management

- *Alkylating agents*—you can treat amyloidosis by alkylating agents like melphalan.
- *Combination therapy*—combination therapy using melphalan, prednisone and fluoxymesterone has reported significant improvement.
- *Renal transplantation*—renal transplantation may be indicated. It will arrest the progression of bone lesion.
- *Debulking of lesion*—debulking of lesion can be carried out in case of macroglossia of tongue.

Porphyria

It is a group of disorders in which there is defect in enzymes involved in heme mechanism. These will result in accumulation of porphyrins.

Classification

- *Erythropoietic porphyria*—there is excessive abnormal porphyrins formation in developing erythrocytes. It is localized to bone marrow.
 - *Uroporphyrin*
 - *Protoporphyrin*.

- *Hepatic porphyria*—in it, liver is the site of excessive porphyrin formation.

- Acute intermittent porphyria
- Porphyria variegata
- Porphyria cutaneous tarda
- Hereditary coproporphyria.

Clinical Features

- *Sex*—it is transmitted as non-sex linked recessive character and both sexes are equally affected.
- *Urine*—the first sign is excretion of red urine containing uroporphyrin which may be noted at birth or apparent at first two year after birth.
- *Photosensitivity*—excessive deposition of the excess porphyrin in the skin lead to photosensitivity. It is absent in the neonatal period but may become apparent during first few years after it becomes exposed to sunlight.
- *Vesiculobullous lesion*—vesicular and bullous eruption appears on face, back and hand, i.e. exposed parts. Vesicle contains a serous fluid which exhibits red fluorescence. Ruptured vesicle heals slowly and leaves depressed pigmented scars.
- *Anemia*—there is often coexisting anemia.
- *Hepatic porphyria*—in this disease, there is abdominal crisis and psychological or metal symptoms. There is demyelination of nerve fibers.

Oral Manifestations

- *Teeth*—the porphyrin has an affinity for calcium phosphate and due to this, deposition of porphyrin occur in dentin. Deciduous and permanent teeth show red or brownish discoloration which under ultraviolet light exhibits red fluorescence due to incorporation of porphyrins during development.
- *Oral mucosa*—bullous, erosive lesions of oral mucosa may be present.
- *Cheilitis and periodontitis*—there is also atrophic cheilitis and advanced periodontal diseases.

Diagnosis

- *Clinical diagnosis*—red urine, photophobia and oral ulcerative lesion will give clue to diagnosis.
- *Laboratory diagnosis*—urine will demonstrate 5-aminolevulinic acid and porphobilinogen in the urine.

Management

- *Venesection*—this will reduce hepatic iron overload.
- *Stoppage of triggering drugs*—use of triggering drugs should be stopped immediately.
- *Intravenous drug*—intravenous drugs of hem arginate, fluids, electrolytes and glucose.

Disturbances in Lipid Metabolism

Lipids are a heterogeneous group of organic compounds which are relatively insoluble in water but, soluble in solvent such as ether, chloroform and benzene.

Classification

- *Simple lipids*—they are esters of fatty acids with various alcohols, i.e. natural fats and waxes.
- *Compound lipids*—they are esters of fatty acids containing groups other than and in addition to an alcohol and fatty acids.
- *Derived lipids*—they are derivatives obtained by hydrolysis of the simple and compound lipids, which still possess the general characteristics of lipids.
- *Miscellaneous*—it includes carotenoids, vitamin E and K.

Function of Lipids

- *Fuel*—lipids act as fuel in the body.
- *Insulation of body*—they insulate the body and protect various internal organs.
- *Building blocks*—they provide building blocks for different high molecular weight substance.
- *Essential fatty acids*—lipids supply the essential fatty acids which cannot be synthesized in the body and are essential in the diet for normal health and growth.
- *Proper functioning of nervous system*—the nervous system is particularly rich in lipids and is essential for proper functioning.
- *Vitamin maintenance*—some vitamins like A, D, E and K are fat soluble, hence lipid is necessary for these vitamins.
- *Carrier*—lipoprotein is also 'carrier' of triglycerides and cholesterol.

Classification of Disorders

- *Non-lipid reticuloendotheliosis*—it is also called as histiocytosis X, idiopathic histiocytosis and Langerhans cell disease. It is inflammatory reticuloendothelioma condition with evidence suggesting that it may be reaction to some type of infection. There is pathological accumulation of histiocytes and eosinophilic leukocytes. It is of 3 types. Nowadays, all these three diseases is called as *Langerhans cell histiocytosis (LCH)*:
 - Hand-Schüller-Christian disease.
 - Eosinophilic granuloma of bone (chronic localized Histiocytosis X)
 - Letterer Siwe disease (acute disseminated histiocytosis X).
- *Lipid reticuloendotheliosis*—it is disturbance in sphingo-myelin and glucosyl ceramide metabolism.
 - Gaucher's disease

- Niemann-Pick disease
- Tay-Sachs disease.

Langerhans Cell Histiocytosis

Nomenclature

In 1893, Hand reported child patient with diabetes insipidus, hepatosplenomegaly with punched out lesion of skull. In 1915 Schüller presented same features with another child patient. In 1920 Christian presented two cases with same features. So initially first entity called Hand-Schüller-Christian disease was established. Histologically, it is now classified as non-lipid reticuloendotheliosis.

In 1924, Letterer reported infant patient who has got low grade fever, hepatosplenomegaly, lymphadenopathy, and cutaneous petechiae with evidence of reticuloendothelial proliferation. In 1933 Siwe described similar cases. So term Letterer Siwe disease term was established.

In 1940, Otani and Ehrlich presented seven cases of solitary granuloma of bone which is subsequently called as eosinophilic granuloma of bone.

In 1953, Lichtenstein proposed a term Histiocytosis X for all the three diseases to indicate that basic disease process is of unknown etiology.

Nowadays, dominant histolytic cells identified as antigen processing Langerhans cells. So it is now called as Langerhans cell histiocytosis (LCH). All the three diseases are now called separated clinical entity under the heading of Langerhans cell histiocytosis.

Variant

- *Hand-Schüller-Christian disease*—it is also called as 'multifocal eosinophilic granuloma', 'chronic disseminated histiocytosis X' or 'xanthomatosis'. It is characterized by widespread skeletal and extraskelatal lesions and chronic clinical course. It is result of error in the metabolism of cholesterol and its esters.
- *Letterer Siwe disease*—It is an acute fulminating disease, which invariably occurs in infants usually before the age of 3 years.
- *Eosinophilic granuloma*—it is also called as 'unifocal eosinophilic granuloma'. It is the lesion of bone which is primarily histiocytes proliferation with an abundance of eosinophilic leukocytes by no intra- or extracellular lipid accumulation.

Clinical Features

Hand-Schüller-Christian disease

- *Age and sex*—it is more common in boys than girls 2:1. Occur in early life usually before age of five.
- *Classic triad*
 - Single or multiple areas of punched out bone destruction in skull.

- Unilateral or bilateral exophthalmos.
- Diabetes insipidus.
- *Facial asymmetry*—involvement of facial bone which is commonly associated with soft tissue swelling and tenderness causing facial asymmetry.
- *Signs*—otitis media and skin may sometimes exhibit papular or nodular lesion.
- *Progress*—course is chronic with numerous remissions and exacerbation.

Letterer-Siwe disease

- *Age*—it is fulminating condition that most often occurs in infants younger than 1 year of age.
- *Onset*—initial manifestation is skin rash involving trunk, scalp and extremities. Rash may be erythematous, purpuric and ecchymotic, some time with ulceration.
- *Symptoms*—patient may have persistent low grade spiking fever with malaise and irritability.
- *Signs*—splenomegaly, hepatomegaly and lymphadenopathy are common. Nodular and diffuse involvement of visceral organs particularly in lung and GI tract. Soft tissue and bony granulomatous reaction, hemorrhage, anemia, failure to thrive

Eosinophilic granuloma

- *Age and sex*—it occurs primarily in older children and young adults and proportion of male to female is 2:1.
- *Site*—skull and mandible are common site but femur, humerus, ribs may be affected.
- *Symptoms*—there may be local pain which may be dull and steady, swelling and tenderness may also be there. General malaise and fever may accompany the eosinophilic granuloma of bone.
- *Sign*—lesion is destructive and well demarcated, roughly round or oval in shape. The area destroyed is replaced by soft tissue. Tissue of early lesion is soft and brown and since there is no necrosis, it is not friable. Later, it become fibrous and grayish.

Oral Manifestations

Hand-Schüller-Christian disease

- *Symptoms*—sore mouth with or without ulcerative lesion, halitosis, and unpleasant taste, loose and sore teeth. There is also history of precocious exfoliation and failure of healing of tooth socket following extraction.
- *Periodontal disease*—loss of supporting alveolar bone mimics advanced periodontal disease.
- *Gingivitis*—inflammation of gingiva is also present.

Letterer-Siwe disease

- *Gingival hyperplasia*—enlargement of the gingival tissue occurs.
- *Ulcer*—there may be presence of ulcer on the oral mucosa.

- *Teeth*—diffuse destruction of bone of maxilla and mandible which may result in loosening and premature loss of teeth.

Eosinophilic granuloma

- *Site*—it may occur in jaws and overlying soft tissues.
- *Juvenile periodontitis*—there is loss of superficial alveolar bone often mimicking juvenile periodontitis.
- *Symptoms*—gingivitis and bleeding gingiva, pain or ulceration is present.
- *Signs*—loosening and sloughing of teeth often occurs after destruction of alveolar bone. Sockets fail to heal normally.

Radiological Features

Hand-Schüller-Christian disease

- *Site*—bone lesion usually seen in membrane bone but can occur in long bones and the mandible.
- *Skull lesion*—the skull lesion may be small or large, single or multiple (**Fig. 39-1**) and they may occur anywhere but anterior portion of the vault and the floor of anterior and middle cranial fossa are commonest site.

Fig. 39-1: Multiple skull lesions seen in patient with Langerhans histiocytosis.

- *Radiodensity*—the lesion is entirely destructive, so there is radiolucency which is usually sharply defined but with no cortical margin.
- *Margins*—it is well defined at periphery with punched out appearance. Margins are smooth or somewhat irregular.
- *Scooped out shape*—this particular appearance occurs because the bone destruction starts below the crest of the alveolar process (**Fig. 39-2**). Usually portions of the superior aspect of crest of the alveolar bone are maintained at the mesial and distal margins of the areas of destruction and produce scooped out appearance.

- *Floating teeth appearance*—destruction of periodontal bone support of one or more teeth especially in the posterior areas while producing virtually no resorption of tooth roots. The result is often a distinctive radiographic appearance of ‘teeth standing in space (floating teeth appearance)’, in the region superior to the mandibular canal.
- *Pathological fracture*—in some cases, there may be complete loss of continuity of the mandible, so that there is pathologic fracture.
- *Effect on surrounding structure*—displacement of erupted teeth and follicle was the most common radiographic finding. In some cases, root resorption can be seen.

Fig. 39-2: Scooped out lesion seen in skull of the patient.

Eosinophilic granuloma

- *Site*—mandible is more commonly affected than maxilla, posteriorly more common than anteriorly.
- *Shape*—eosinophilic granuloma may be solitary or multiple and the lesions are circular or elliptical in shape.
- *Margin*—it is moderately well defined at its radiographic periphery.
- *Punched out appearance*—the lesion in the jaw have fairly discrete borders, which are rarely hyperostotic. Thus they have punched out appearance.
- *Floating teeth appearance*—jaw lesions of eosinophilic granuloma are usually seen as areas of pure osteolytic activity in close vicinity to the alveolar processes.
- *Periosteal new bone*—periosteal new bone formation is observed in some cases.
- *Bone sclerosis*—sclerosis is a common observation in inflammatory lesions of the jaws and the fact that it appears frequently in the alveolar bone lesions by communication of the lesions with the oral cavity that results in superimposed infection.

Diagnosis

- *Clinical diagnosis*—punched out destruction of skull, diabetes insipidus, ulcerative lesion, skin lesion with exophthalmos will give clue to diagnosis.
- *Laboratory diagnosis*—biopsy shows Langerhans cells which contain rod shaped cytoplasmic structure known as Birbeck granules. Plasma cells, lymphocytes, and multinucleated giant cells are also seen. Patient also suffers from anemia and less frequently leukopenia and thrombocytopenia. Serum cholesterol level is normal but tissue cholesterol level is raised.

Differential Diagnosis

- *Oral carcinoma*—found in older age.
- *Primordial cyst or dentigerous cyst*—they are more or less rounded while xanthoma is not likely to be round.
- *Benign giant cell tumor*—they usually contain some bone within the cavity while xanthoma does not. They also cause expansion of the bone. While in case of xanthoma there is no expansion of the bone.
- *Traumatic bone cyst*—they have got well defined border as compared to histiocytosis.
- *Fibrous dysplasia*—they have got clearly marked and corticated borders.
- *Apical infection*—in this case, pulp is dead.
- *Cherubism*—limited to jaw and it is bilateral.
- *Metastatic carcinoma*—incidence of histiocytosis is higher in children. A history of primary tumor helps to distinguish multiple punched out bony lesions of histiocytosis X and metastatic carcinoma.
- *Leukemia*—jaw bone lesions are most common at the crest of the alveolar ridge. But in contrast, those of leukemia characteristically originate in the deeper medullary portion.
- *Multiple myeloma*—it has to be differentiated by laboratory tests. The ratio of albumin to globulin is reserved and Bence Jones proteins are present in the urine in multiple myeloma.

Management

- *Curettage*—it is usually treated by curettage or excision of lesion.
- *Radiation*—the lesions which are inaccessible are treated by irradiation.
- *Corticosteroids*—intralesional injection of corticosteroids may be effective in local lesion.
- *Chemotherapy*—patients with acute disseminated disease, may be given drug treatment like prednisolone, vinblastine, etoposide, and cyclophosphamide.

Gaucher's Disease

It may be familial and is thought to be due to faulty metabolism of the lipid, kersin. Lack of glucocerebrosidase results in accumulation of glucosylceramide within lysosomal cells of macrophages and monocytes lineage. The reticular cells and histiocytes are increased in number and many of them become infiltrated with kersin. They become accumulate in bone marrow of this patient. It is autosomal recessive.

Types

- *Type I (chronic non-neuropathic)*—there is no cerebral involvement.
- *Type II (acute neuropathic)*—it is characterized by hepatosplenomegaly and central nervous system disorders.
- *Type III (subacute neuropathic)*—it resembles type II but later in onset and has more protracted clinical course.

Clinical Features

- *Age*—it is mostly seen in adults and progress is slow.
- *Signs*—there is enlargement of the lymph nodes, spleen and to a lesser extent the liver.
- *Symptoms*—there may be bone pain due to changes in bone marrow. There is often bleeding from the nose or from the gums. Teeth extraction from the affected area may result in bleeding complications.
- *Signs*—there is hepatosplenomegaly and CNS involvement. Patient also suffers from anemia and thrombocytopenia.
- *Pingueculae*—the skin is sometimes pigmented and the conjunctival fibrous tissue may be thickened and of brownish discoloration, a condition known as 'pingueculae'.
- *Prognosis*—the prognosis of malignant infantile form is very poor; the disease results in death usually within the first year.

Radiographic Features

- *Rarefaction*—bone changes occur due to destructive infiltration of the cerebrosidic reticulosis of the bone marrow. As a result of this and proliferation of cells so called Gaucher cells, the bone undergoes rarefaction.
- *Porosity*—there may be generalized porosity of the mandible and maxilla, with loss of trabecular structure. Sometimes, there is porosity in the mental region and thinned out mandibular cortex and areas of osteolysis present in maxillary premolar area.
- *Worm eaten appearance*—pseudocystic radiolucent areas in the molars and premolars with 'worm eaten appearance' can be seen.

Diagnosis

- *Clinical diagnosis*—pingueculae on skin, features of anemia and thrombocytopenia with hepatosplenomegaly may give clue to the diagnosis.
- *Radiological diagnosis*—worm eaten appearance with loss of lamina dura.
- *Laboratory diagnosis*—biopsy of spleen and liver show typical Gaucher cells which are round pale cells, containing a small eccentric nucleus and wrinkled or crumpled silk cytoplasm.

Management

- *Glucocerebrosidase*—enzyme replacement therapy with macrophages targeted glucocerebrosidase is used.

Niemann-Pick Disease

It is also called as '*sphingomyelin lipidosis*'. It is characterized by an abnormal storage of phospholipids due to lack of sphingomyelinase.

Clinical Features

- *Site*—it involves lungs, liver and the nervous system.
- *Signs*—there is hepatosplenomegaly, retarded physical and mental growth and severe neurological disturbance.

Diagnosis

- *Clinical diagnosis*—not so specific.
- *Laboratory diagnosis*—biopsy shows presence of foam cells, usually an enlarged reticuloendothelial cell whose cytoplasm contains numerous droplets-like inclusion of lipid.

Management

- *Symptomatic*—it is only symptomatic to control the infection. Death usually occurs within 3 years of age.
- *Others*—enzyme replacement therapy and organ transplantation are also carried out.
- *Genetic counseling*—it should be provided for the affected family.

Tay-Sachs Disease

It is caused by lack of hexosaminidase A, which results in the accumulation of ganglioside within lysosomes of neurons. This condition is heterogeneous. There is progressive neuronal degeneration developing after birth. Death occurs at 3 to 5 years of age.

Disturbances in Carbohydrate Metabolism

Classification

- *Monosaccharide*—these are those carbohydrates which cannot hydrolyze further to yield smaller carbohydrates. For example: glucose and fructose.
- *Oligosaccharides*—these are condensation product of two to three monosaccharides. For example: sucrose, maltose, lactose and raffinose.
- *Polysaccharides*—these are high molecular weight polymers of monosaccharide. For example: cellulose, starch, glycogen and dextrin.

Function

- *Energy source*—carbohydrates are the best source of energy for human body.
- *Fuel for fetus*—glucose is a major fuel of mammalian tissue and a universal fuel of fetus.
- *Cell membrane*—carbohydrates occur in cell membrane.

Hurler's Syndrome

It is disturbance of mucopolysaccharide metabolism, which is characterized by elevated mucopolysaccharide excretion ratio and an excessive intracellular accumulation of chondroitin sulphate B and heparin sulphate in those tissue and organ where they are normally found. It is inherited as an autosomal recessive trait.

Clinical Features

- *Age*—it usually becomes apparent within first two years of life, progresses during early childhood and adolescence and terminates in death before puberty.
- *Signs*—head is large, prominent forehead, broad saddle nose and wide nostrils, hypertelorism and puffy eyelids with coarse bushy eyebrows, thick lip, large tongue, open mouth and nasal congestion and noisy breathing (**Fig. 39-3**).
- *Abdomen*—progressive corneal clouding, hepato-splenomegaly resulting in protuberance of abdomen.
- *Claw hand*—a short neck and spinal abnormalities are typical, while flexion contractures result in the 'claw hand' (**Fig. 39-4**).

Oral Manifestations

- *Mandible*—shortening and broadening of mandible with prominent gonions and wide intergonial distance.
- *Teeth*—there is typical spacing of teeth. Teeth are small and misshapen.
- *Gingiva*—there may be gingival hyperplasia.

Fig. 39-3: Hurler syndrome showing large head and prominent forehead (Courtesy Dr Shetty).

Fig. 39-4: Claw hand seen in Hurler syndrome (Courtesy Dr Shetty).

Radiological Features

- *Bone destruction*—localized areas of bone destruction in the jaws may be found which appear to represent hyperplastic dental follicles with large pool of metachromate material probably mucopolysaccharide.
- *Dentigerous cyst type appearance*—radiolucent area resembles a dentigerous cyst.

Diagnosis

- *Clinical features*—open mouth appearance (**Fig. 39-5**), claw hand and puffy eyelid will diagnose this condition.
- *Radiological diagnosis*—destructive lesion of bone is seen radiologically.

Fig. 39-5: Open mouth appearance seen in Hurler syndrome (Courtesy Dr Shetty).

- **Laboratory diagnosis**—there is excessive accumulation of intracellular mucopolysaccharide in many tissues and organs throughout the body including liver, spleen, reticuloendothelial system, nervous system, cartilage, bone and heart. Abnormal deposits are found in many sites with involved fibroblasts assuming the appearance of clear (gargoyle) cells. There is elevated level of mucopolysaccharide in the urine.

Management

Death usually occurs before the age of ten due to pneumonia and cardiac failure.

Lipoid Proteinosis

It is described in Chapter 11: Keratotic and Nonkeratotic Lesions.

Hereditary Fructose Intolerance

It is transmitted as autosomal recessive trait. It results from a deficiency in fructose 1-phosphate aldolase. It is manifested by hypoglycemia and vomiting after ingestion of fructose containing foods. Affected individuals rapidly acquire an intense aversion to all sweets and fruits. There are fewer incidences of caries in these individuals.

Hypoglycemia

It is a subnormal blood glucose level. It is caused by delayed meal, inadequate total caloric intake, unusual physical

exertion, insulin measurement error, insulin overdose, the “brittle” diabetic, and oral hypoglycemic agents.

Clinical Features

- **Symptoms**—sudden onset of hunger, sweating, shakiness, tremor, anxiety, restlessness, faintness, weakness, nausea, palpitations. Progression to mental confusion, bizarre behavior, personality change, reduced level of consciousness, loss of consciousness, seizures.
- **Signs**—pulse rapid, blood pressure may be elevated and moderate hypothermia may be present due to sweating, hyperventilation and vasodilatation.
- **Other features**—bizarre or aggressive behavior may be present, staggering gait, may appear drunk, cold and clammy skin.

Diagnosis

- **Clinical diagnosis**—hunger onset, anxiety and mental confusion will give clue to the *diagnosis*.
- **Laboratory diagnosis**—blood glucose reduced.

Management

- **Consult physician**—consult physician, ensure that the airway is patent and protected and that ventilation is adequate in the patient with a reduced level of consciousness.
- **Determination of serum glucose**—determine the serum glucose with glucometer and give the conscious patient a glass of orange juice or some other form of rapidly absorbed sugar.
- **Glucose administration**—when patient is unable to take glucose orally, then give: adult—Glucagons 1 mg IM/SC, if no response may repeat in 5-20 minutes, child—Glucagons 0.025 mg/kg IM/SC, if no response may repeat in 5-20 minutes.
- **Glucagon**—glucagon is well absorbed and a response should be seen within 5 minutes. It is less sclerosing to veins than Dextrose 50% in water, start an IV with normal saline to keep vein open.

Disturbances in Mineral Metabolism

Acrodermatitis Enteropathica

It is also called as ‘zinc deficiency’. Rare disease of infancy and childhood, transmitted as autosomal recessive character. Since supplements appear to be curative even pathogenesis of the characteristic lesions involves a number of etiologic factors.

Clinical Features

- **Age**—it is usually occur in childhood after weaning.
- **Symptoms**—the primary signs of the disorder are skin lesion, hair loss, nail changes and diarrhea.
- **Signs**—erythematous, pustular, moist erosions of the orofacial areas occur as an early manifestation. In fully developed conditions, the buttocks, elbows, fingers and toes are affected by vesiculobullous rash similar to that affecting the orofacial region. Retarded body growth and mental changes also occur with some frequency.

Oral Manifestations

- **Site**—the buccal mucosa, palate, gingiva and tonsils.
- **Candidiasis**—large number of children suffer from candidiasis.
- The perioral area usually being affected by weeping erosions, angular fissuring and spreading dermatitis.
- **Papilloma**—there may be numerous small whitish papillomas on the buccal mucosa and borders of the tongue.
- The oral changes are sometimes described as 'stomatitis', 'glossitis' and 'stomatitis producing thrush like picture'.
- **Signs**—buccal mucosa is present with red and white spots, erosions, ulcers and desquamation.
- **Tongue lesion**—lesion on the tongue is sometime papillated and halitosis is often severe.

Diagnosis

- **Clinical diagnosis**—stomatitis, skin lesion, and hair loss will give clue to the diagnosis.
- **Laboratory diagnosis**—serum level of zinc is decreased.

Management

- **Zinc sulfate**—220 mg of zinc sulfate tds daily produces remarkable improvement.

Phosphorus

Phosphates form an intermediate stage in the metabolism of fats and carbohydrates by their function in phosphorylation. They are used in building the more permanent organic phosphates including some catalysts essential to the structure and function of cells. They are utilized in the formation of phosphoproteins, such as milk casein and in the formation of the nerve polypeptides. They provide the energy rich bonds such as adenosine triphosphate, which is important in muscle contraction and they form part of such coenzymes as pyridoxal phosphate, which is necessary in decarboxylation and transmission of certain amino acids such as tyrosine, tryptophan and arginate.

The suggested dietary intake of phosphorus ranges from 240 mg for infants to 800 mg for adults. It is increased in lactating and pregnant women by 50%.

Hypophosphatasia

It is a hereditary disease transmitted as a recessive autosomal characteristic. There is deficiency of serum alkaline phosphate. It resembles rickets. There is low level of serum alkaline phosphatase activity and elevated urinary excretion of phosphorylethanolamine which result in formation of defective bone matrix.

Types

- **Perinatal type**—it is diagnosed at birth and death occurs within few hours of birth. Death occurs due to respiratory failure.
- **Infantile type**—it appears at 6 months of age.
- **Juvenile type**—this appears in childhood and has wide range of clinical expression.
- **Adult type**—it is mild form and appear late in life.

Clinical Features

- **Symptoms**—there is anorexia, irritability, persistent vomiting and mild pyrexia.
- **Infantile form**—severe hypocalcemia, bone abnormalities and failure to thrive manifest the infantile form. Most of the cases are lethal. Deformities of rib may be seen in these patients.
- **Juvenile form**—hypophosphatasia of childhood is characterized by increased infection, growth retardation (**Fig. 39-6**) and rochite-like deformities including deformed extremities, costochondral junction enlargement (rochite rosary) and pulmonary gastrointestinal and renal disorders.
- **Adults form**—the adult form includes fracture with a prior history of rickets and osseous radiolucency. Stress fracture of metatarsal bones of feet may be presenting sign of this condition.
- **Homozygous involvement**—disease with homozygous involvement begins *in utero* and patient die within 1st year. Bowed limb bone and marked deficiency of skull ossification.
- **Heterozygous involvement**—in heterozygous, there is milder effect with poor growth and fracture and deformities.
- **Skull**—skull suture close early resulting in bulging suture and gray marking on internal surface of skull which occur due to increased intracranial pressure. Shape of skull is brachiocephalic.
- **Pseudohypophosphatasia**—disease resembling classic hypophosphatasia but with normal serum alkaline phosphatase level. There is osteopathy of long bones and skull. There is premature loss of deciduous teeth.

Fig. 39-6: Growth of this child is retarded due to hypophosphatasia (Courtesy Dr Manish Thadani).

Oral Manifestations

- *Premature loss of teeth and root resorption*—there is almost total lack of cementum and normally attached periodontal fiber leading to poor support and premature loss of teeth in deciduous teeth (Fig. 39-7). There is also delayed eruption of permanent teeth. The roots either fails to develop fully or undergo early resorption of the apices.
- *Hypoplasia*—teeth may be hypoplastic.
- *Pulp chamber and root canal*—the pulp chamber and root canal are sometimes larger than normal.

Fig. 39-7: Premature loss of primary teeth in child plus enamel hypoplasia is seen (Courtesy Dr Manish Thadani).

- *Alveolar bone*—the alveolar bone which support the teeth fail to develop normally which result in premature loss of primary teeth.
- *Gingiva*—there is inflammation of the gingiva.

Radiographic Features

- *Irregular ossification*—the metaphyses of long bones have been described as showing a spotty, streaky or irregular ossification.
- *Long bone*—elongated very fine processes of uncalcified tissue extend longitudinally into the poorly formed osseous tissue at the ends of long bones. Periosteal new bone formation may be present along the shaft of the long bones.
- *Skull*—skull show poor calcification.
- *Beaten copper appearances*—multiple radiolucent areas on skull called *gyral* or *convolutions* marking which described as beaten copper appearance which results due to increased intracranial pressure.
- *Jaw bone*—generalized reduction in bone density.
- *Lamina dura*—cortical and lamina dura thinning and alveolar bone deficiency.
- *Teeth*—reduced enamel thickness, enlarged pulp chamber and root canal and presence of large pulp chamber as well as alveolar bone loss.

Diagnosis

- *Clinical diagnosis*—premature loss of teeth is typical feature of this disease.
- *Radiological diagnosis*—beaten copper appearance seen and there is also thinning of lamina dura.
- *Laboratory diagnosis*—reduce level of bone, liver and kidney isozyme of alkaline phosphatase. There is also increased level of blood and urinary phosphoethanolamine. Biopsy shows abundant poorly mineralized osteoids.

Management

- *Symptomatic*—treatment of hypophosphatasia usually is symptomatic as infusion of alkaline phosphatase is not successful.
- *Prosthetic appliance*—these are given to replace missing tooth.
- *Genetic counseling*—this should be carried out to identify carriers of defective gene.

Calcium

- *Action*—it plays a large role in the formation of bones and teeth. It is also useful in the maintenance of skeletal structure, tooth structure, normal membrane permeability, normal heart rhythm and other neuromuscular

activities. It is one of the important constituent in coagulation of the blood.

- *Daily requirement*—daily recommended calcium intake of 360 mg for newborn and infants and 800 mg for children and adults. Adolescents and pregnant and lactating women are advised to increase their daily dietary calcium intake by 50%, i.e. 1200 mg.
- *Absorption and excretion*—only about 1/3rd of daily intake of calcium is absorbed under normal conditions. High protein diet has shown to increase calcium absorption. Calcium is excreted in both faeces and urine.
- *Deficiency*—deficiency may lead to internal hemorrhage and generalized paralysis can occur. There may be hyperirritability and tetany with characteristic carpopedal spasm and sometimes laryngospasm and convulsion. Derangement of blood coagulation and the integrity of the capillaries.

Magnesium

- *Action*—magnesium appears to participate practically in every phosphorylating mechanism. It is also needed for activity of certain enzymes such as phosphatase and carboxylase.
- *Daily requirement*—the recommended daily dietary allowance for magnesium ranges from 50 mg for infants to 400 mg for teenage males. A daily increase of 150 mg is suggested during pregnancy and lactation.
- *Deficiency*—deficiency of magnesium occurs due to gastrointestinal loss of the mineral resulting from frequent diarrhea and vomiting.
 - *Neuromuscular hyperirritability*—patients with deficiency exhibit severe neuromuscular hyperirritability including carpopedal spasm and a positive Chvostek sign, athetosis movements, marked susceptibility to auditory, visual and mechanical stimuli, a decreased serum magnesium level and normal calcium level.
 - *Personality changes*—there may be personality changes, anorexia, nausea and vomiting.
 - *Tetany*—the tetany appears when the serum magnesium level is depressed below 1.30 mEq per liter.
 - *Oral manifestation*—there may be localized degeneration with enamel hypoplasia of the teeth.
 - *Management of deficiency*—treatment is done by intramuscular injection of magnesium sulfate followed by a prompt rise in serum magnesium and a concomitant disappearance of the tetany and the convulsion.
- *Excess*—the administration of magnesium containing antacids to patients with renal insufficiency has resulted in central nervous system depression. There may be severe voluntary muscle paralysis. High magnesium intake will produce rickets in growing animals.

Sodium

- *Action*—sodium plays an important role in the maintenance of the acid base equilibrium as well as of osmotic pressure which depends on total base.
- *Daily requirement*—the minimum requirement of salt is thought to be about 0.5 gm.
- *Absorption and excretion*—the kidney is the principal organ for excretion of water and salt. When the diet is low in salts and when there is profuse sweating, there is no sodium found in the urine. The regulatory mechanism controlling the reabsorption of sodium by the renal tubules is controlled by adrenal gland.
- *Deficiency*—sodium deficiency occurs in man probably when diet very low in salt is used for long period of time. It is associated with gradual weakness, excessive fatigue, lassitude, apathy, anorexia, a sense of exhaustion, nausea, muscle cramps and peripheral vascular collapse.

Potassium

- *Daily requirement*—most of potassium is intracellular and average requirement of potassium is 2 to 4 gm daily. The requirement is greatest during periods of rapid growth.
- *Excretion*—about 90% of potassium is excreted in the urine.
- *Deficiency*—deficiency may occur due to loss of potassium through diarrhea and vomiting, malnutrition state, administration of diuretics and ion exchange resins, excessive dose of cortisone or hydrocortisone and diabetic acidosis during insulin therapy. The signs of potassium deficiency are primarily those of muscular irritability, muscular weakness, reduced or absent reflex, mental confusion, paralysis, disturbance in conductivity and contractility of heart muscle and alterations in the gastrointestinal tract.
- *Hyperkalemia*—it may result from extensive tissue breakdown, adrenal insufficiency, advanced dehydration on administration of excessive amounts of potassium. Hyperkalemia will produce mental confusion, numbness and tingling of the extremities, pallor, cold skin, weakness, disturbances in cardiac rhythm and peripheral collapse.

Miscellaneous Disorders

Malabsorption Syndrome

It is also called as 'sprue', 'idiopathic steatorrhea', 'celiac disease'. It includes conditions causing poor digestion or absorption to a variable degree of a number of nutrients, fats, proteins, carbohydrates, vitamins, minerals and water. The defective absorption may be due to defective digestive

or defective intestinal absorption. This disturbance in calcium metabolism may result in osteoporosis and other skeletal anomalies.

Clinical Features

- *Prodromal symptoms*—it usually begins with intestinal disturbances including diarrhea, constipation and flatulence.
- *Symptoms*—nervous irritability, numbness and tingling of the extremities occur; malaise and generalized weakness are also common.
- *Signs*—the skin changes include irregular brownish pigmentation particularly on the face, neck, arms and legs and drying of skin with scaly eruptions.

Oral Manifestations

- *Glossitis*—there may be severe glossitis with atrophy of filiform papilla, although the fungiform papillae persist for some time on the atrophic surface.
- *Symptoms*—painful burning sensation of the tongue and oral mucosa are common.
- *Signs*—there are small projections which are pink or red in color and the erythematous swelling and palatal lesions appear as multiple aphthous ulcers.

Diagnosis

- *Clinical diagnosis*—intestinal disturbances with glossitis, and erythematous swelling.
- *Laboratory diagnosis*—there is low blood calcium level.

Management

- *Vitamin*—administration of vitamin B₁₂ and folic acid.
- *Diet*—diet must be carefully supervised and supplemented with vitamins and minerals.

Section **5**

Drugs used in Dentistry

Introduction

Antibiotics are chemical substances produced by microorganisms (fungi, actinomycetes, bacteria) that suppress the growth of other microorganisms and may eventually destroy them. Waksman and Woodruff in 1942 formally defined an antibiotic as a chemical substance produced by microorganisms, which at a high dilution can inhibit the growth and/or multiplication or kill another microorganism.

Antimicrobial drugs are the greatest contribution of the present century to therapeutics. The purpose of antibiotic/antimicrobial chemotherapy is to aid the host defenses in controlling and eliminating microbes that temporarily have overwhelmed the protective host mechanisms. Antimicrobial agents share pharmacokinetic determinants with other drugs, including ability to pass through membranes (absorption), diffuse through extracellular fluids (distribution), undergo biotransformation by hepatic enzymes (metabolism) and be eliminated from the body by renal or fecal routes (excretion).

In addition, each antimicrobial agent demonstrates unique pharmacokinetic properties including the acidic dissociation constant (pKa), lipid solubility, plasma protein binding, volume of distribution (degree of dispersal of the drug through the intracellular and extracellular fluids) and rate and type of hepatic metabolism or renal excretion. The volume of distribution and hepatic and renal excretion ratios constitute the major determinants of a drug's half-life (the time required for the peak concentration of a drug to fall by one half in a given body fluid).

The antimicrobial therapy, which targets a living organism with a physiology different from that of host, by the influence of the variables such as microorganism density, growth phase, ease of development of resistance and glycocalyx formation capable of interfering with antibiotic diffusion.

The determinants of the clinical outcome of antimicrobial therapy includes the nature and virulence of the offending organism, site of infection, possibility of establishing surgical drainage, ability of antibiotic to penetrate to the infected site, postantibiotic effects, adverse drug reactions and efficiency of the host defenses.

Since it is a unique host-parasite interaction, the unit dosages, dosing intervals and duration of therapy are not yet precisely established for the majority of specific infections.

The word '*chemotherapy*' can be defined as the use of chemical compounds in the treatment of infections, so as to destroy offending organisms or parasites without damaging the host tissues.

A chemotherapeutic agent may act by destroying the organism (bactericidal) or by inhibiting its growth (bacteriostatic). These drugs can hit at least 4 targets in bacteria: cell wall, cytoplasmic membrane, ribosomes and RNA molecules involved in transcription of genetic information.

Classification

Antimicrobial drugs can be classified in many ways:

According to Chemical Structure

- *Sulfonamides and related drugs*—Sulfadiazine and others, Sulfones-Dapsone (DDS), Para Aminosalicic acid (PAS)
- *Diaminopyrimidines*—Trimethoprim, Pyrimethamine
- *β -lactam antibiotics*—Penicillin, Cephalosporin
- *Tetracycline*—Oxytetracycline, Doxycycline
- *Nitrobenzene derivative*—Chloramphenicol
- *Aminoglycosides*—Streptomycin, Gentamycin, Neomycin etc
- *Macrolide*—Erythromycin, Oleandomycin
- *Polypeptide antibiotics*—Polymyxin-B, Colistin, Bacitracin, Tyrothricin

- Nitrofurans derivative—Nitrofurantoin, Furazolidone
- Nitroimidazoles—Metronidazole, Tinidazole
- Quinolones—Nalidixic acid, Cinoxacin, Rosaxacin
- Nicotinic acid derivative—Isoniazid, Pyrazinamide, Ethionamide
- Polyene antibiotics—Nystatin, Amphotericin B, Hamycin
- Imidazole derivative—Miconazole, Ketoconazole, Clotrimazole
- Others—Rifampin, Clindamycin, Spectinomycin, Vancomycin, Lincomycin, Sodium fusidate, Cycloserine, Viomycin, Ethambutal, Thiacetazone, Clofazimine, Griseofulvin.

According to Mechanism of Action

- Interference with cell wall synthesis—Penicillin, Cephalosporin, Bacitracin, Vancomycin and Cycloserine C
- Damage to cytoplasmic membranes—Polypeptides: Polymyxins, Colistin, Bacitracin
- Polyene antibiotics: Amphotericin B, Nystatin, Hamycin
- Inhibition of protein synthesis and impairment of function of the ribosomes—Aminoglycosides, Tetracycline, Chloramphenicol, Macrolide and lincomycin
- Interference with transcription/ translation of genetic information (misreading of mRNA code)—Quinolones, Metronidazole, Rifampin and Ethambutol
- Antimetabolite action—Sulfonamides, Sulfones, PAS and Trimethoprim
- Binding to viral enzymes essential for DNA synthesis (Interfere with DNA function)—Vidarabine, Acyclovir

According to Type of Organism against which Primarily Active

- Antibacterial—Penicillin, Aminoglycosides, Erythromycin etc
- Antifungal—Griseofulvin, Amphotericin B, Miconazole
- Antiviral—Idoxuridine, Acyclovir, Amantadine
- Antiprotozoal—Chloroquine, Pyrimethamine, Metronidazole, Diloxamide
- Anthelmintic—Mebendazole, Piperazine, Pyrantel, Niclosamide.

According to Spectrum of Activity

- Narrow spectrum—Penicillin G, Streptomycin, Erythromycin
- Broad spectrum—Tetracycline, Chloramphenicol

According to Type of Action

- Primary bacteriostatic—Sulfonamides, Tetracycline, Chloramphenicol, Erythromycin, Ethambutol

- Primary bactericidal—Penicillins, Cephalosporins, Aminoglycosides, Polypeptides, Rifampin, Cotrimoxazole, Vancomycin, Nalidixic acid, Isoniazid (Some primary 'static drugs' may become 'cidal' at higher concentrations, e.g. Sulfonamides, Erythromycin etc.; On the other hand some 'cidal' drugs may only be static under certain circumstances, e.g. Cotrimoxazole, Streptomycin).

According to Antibiotics Obtained From

- Fungi—Penicillin, Cephalosporin, Griseofulvin
- Bacteria—Polymyxin B, Colistin, Bacitracin, Tyrothricin
- Actinomycetes—Aminoglycosides, Tetracyclines, Chloramphenicol, Macrolides, Polyenes
- Entirely by chemical method—Chloramphenicol

According to the Organisms Susceptible

- Antibiotics mainly effective against Gm +ve bacteria—For systemic infections, e.g. Penicillins, Macrolides. For topical use, e.g. Bacitracin
- Antibiotics mainly effective against Gm-ve bacteria—For systemic, e.g. Streptomycin and other Aminoglycosides
- Antibiotics effective against both Gm +ve and Gm-ve bacteria—For systemic infections: Ampicillin, Amoxicillin, Cephalosporins, etc. For topical use: Neomycin, Framycetin
- Antibiotics effective against both Gm +ve and Gm-ve bacteria: Rickettsiae and Chlamydia—Tetracyclines, Chloramphenicol
- Antibiotics effective against acid-fast bacilli (*Mycobacterium tuberculosis*)—Streptomycin, Rifampin, Kanamycin
- Antibiotic effective against protozoa—Tetracycline
- Antibiotic effective against fungi—Nystatin, Amphotericin B, Griseofulvin
- Antimalignancy antibiotics—Actinomycin D, Mitomycin.

Routes of Drug Administration

Route and time of administration are major factors in determining ultimate concentration at the site of infection.

Antimicrobial drugs can be administered:

- Topically/ Locally
- Orally
- Intramuscular injection
- Intravenous injection

With few exceptions, the absorption of antibiotics given orally is decreased in the presence of food. Some antibiotics are acid unstable and nearly complete inactivation of these drugs will occur if it is taken just before and after meals when gastric secretions are high. Therefore, in general, antibiotics should be taken no sooner than 1 hour before or

at least 2 hours after a meal. In addition, interaction with other orally administered drugs can decrease the external absorption of some antibiotics. For example, the absorption of tetracycline is decreased by milk, by antacids containing divalent and trivalent metallic cations and by medications containing iron salts.

Antimicrobial Dosing Principle

The proper dose of a drug is the amount that produces the maximum benefit, with the least attendant harm, i.e. with minimal adverse effects on the physiology of the host and the microbial ecology.

- *Vigorous dosage*—the current trend in antimicrobial therapy is to give a vigorous dosage for a short time as the clinical situation permits. Such a regimen is desirable since a major factor in the success of most antimicrobial agents is the height of the concentration in the serum and in the infected tissue by the drug. High concentrations are more critical with aminoglycoside, metronidazole and quinolones (concentration-dependent antibiotics), whereas prolonged exposure of the organism to the antimicrobial agent is more critical with β -lactams (time-dependent antibiotics). Prolonged dosing beyond what is necessary increases the antibiotic toxicity, allergy and selection of resistant microorganisms.
- *Loading dose*—use of an oral antibiotic loading dose: Without a loading dose, it takes 6-12 hours to achieve maximum therapeutic blood and tissue levels via oral administration.
- *Achieving maximum blood level*—achieve blood levels of the antibiotic at 2-8 times the minimal inhibitory concentration. Such blood levels are necessary to compensate for the tissue barriers that impede antibiotic penetration to the site of the injection.
- *Use frequent dosing intervals*—this is important with the older β lactam antibiotics such as penicillin V and the first generation cephalosporins so as to maintain relatively constant blood levels.
- *Determine duration of therapy by remission of disease*—the antimicrobial agents is terminated when the patient host defenses have gained control of the infection and the infection is reasonably certain to resolve or has resolved.
- *Improper dosing*—it may be in 3 forms:
 - Inadequate concentration of drugs
 - Inadequate duration of therapy
 - Excessive dosage (leading to toxic effects in the host).

Duration of Antibiotic Therapy

A significant misconception in antibiotic therapy is that antibiotic use requires a “complete course” of therapy.

Conceptual errors about a preordained “course” of antimicrobial therapy emanate from several faulty assumptions:

- *Resistant microorganism*—prolonged antimicrobial therapy destroys resistant microorganisms. This is a contradiction in terms, as antimicrobial agents cannot affect microorganism resistant to them and the prolonged use of antimicrobial agents only serves to select for these resistant species.
- *Rebound infection*—prolonged antibiotic therapy is necessary for “rebound” infections that recur since the organisms are suppressed but not eliminated. Acute orofacial infections do not rebound particularly if the source of the infection is probably eradicated.
- *Variability in infectious process*—antibiotic dosages and duration of therapy can be extrapolated from one infection to another. This is not possible to give the variability in infectious processes.
- *Remission and relapse of infection*—according to Norsby S. R (1991) the ideal duration of antibiotic therapy is the shortest that will prevent both clinical and microbiological relapse. According to Leitman P. S (1990), the only practical guide for determining the effectiveness of antimicrobial treatment and hence the duration of therapy is clinical improvement of the patient as judged by remission of the infection. Acute orofacial infections have a rapid onset and relatively short duration of 2-7 days or less, particularly if the offending cause is treated or eliminated. If clinical experience and the nature of the infection dictate that it is anticipated course, if it will be 3 days, then 3 days of antibiotic therapy is enough; if 5 days, then 5 days of therapy, etc. When clinical evidence indicates that the infection is reasonably certain to resolve or is resolved, the antibiotic therapy should be terminated.
- *Rule of thumb*—according to the rule of thumb, antibiotic coverage should last for at least 48 hours after complete remission of clinical symptoms. Treatment of the usual oral infections of bacterial origin requires an average of 5-7 days of antibiotic therapy.

Effectiveness of Antibiotics

Age, Type and Extent of Infection

The time duration of the presence of an infection plays a significant role in determining the effectiveness of antibiotic therapy. Older, well established infections grow slowly and thus both bactericidal and bacteriostatic antibiotics are less effective than they would be in new infections.

The larger the size or extent of infection, the less effective the antibiotic therapy will be, because the increased number of bacteria generally requires a higher concentration of antibiotic be present at the site of infection.

Antibiotics by themselves cannot be relied on to eradicate some infections. Appreciable quantities of pus, necrotic tissue, a foreign body and abscessed areas that are relatively avascular require prompt surgical management in addition to adequate doses of antimicrobial agents.

Resistance

Some species of bacteria are protected against the action of certain antibiotics by virtue of the fact that the drug will not reach the target site (e.g. cell wall may be impermeable). Also, bacteria that would normally be expected to be susceptible to a particular antibiotic can develop resistance. Resistance to antimicrobials can be produced by a number of mechanisms.

- *Decreased permeability*—By the decrease in the permeability of the bacterial cell membrane to the drug (e.g. resistance to ampicillin).
- *Inactivation of drug*—by inactivation of the drug by enzymes of bacteria (e.g. Betalactamase inactivates some penicillin).
- *Alteration of drug receptor*—by alteration of the drug receptor site in bacteria (e.g. in erythromycin, there is a change in the ribosomal binding site).
- *Alternative metabolic pathway*—by the development of an alternative metabolic pathway in bacteria which are unaffected by the drug (e.g. in sulfonamide resistance).
- *Increases elimination of drug*—by increased elimination of drugs from the bacterial cell (e.g. Fluoroquinolones may be actively expelled from the cell).
- *Mutation*—resistance can develop from one bacterial generation to the next by mutation (vertical transfer). Mutation is not a result of exposure to antibiotics but there are spontaneous mutations occurring continually in the bacterial population and some of them will coincidentally confer resistance.

Patient Compliance

This is a very important factor since patients may miss doses when clinical symptoms begin to subside and a patient may choose to discontinue therapy as soon as overt symptoms are absent. Premature termination of drug therapy will favor selection of microorganisms that are more resistant to the drug. Particularly with bacteriostatic agents, patient compliance is a requisite for a successful clinical outcome.

Concentration of Antibiotics at the Site of Infection

To be effective, an antibiotic must reach the site of infection in amounts above the MIC for infecting microorganism. (MIC—Lowest concentration needed to inhibit visible growth of an organism on media after 18-24 hours of incubation).

Metabolism and Excretion of Antibiotics

Alteration of a drug within a living organism is known as biotransformation. The time during which an antibiotic is present in effective concentration at the site of infection depends on the rate of inactivation of the drug through metabolism or excretion or both. Based on this, the dose is repeated at specific intervals so that antibacterial blood concentration is maintained. After absorption, drugs can undergo 3 possible fates:

- Metabolic degradation by enzymes (by oxidation, reduction or hydrolysis)
- Spontaneous change into other substances
- Excretion as the same or unchanged.

Penicillins, cephalosporin, aminoglycoside and polymyxins are excreted mainly through kidney. Other antibiotics undergo varying degree of biotransformation in the liver.

Indications for Antibiotics

Therapeutic

- In patients where the host response is decreased by diseases like diabetes mellitus, immunoglobulin deficiency, malnutrition and alcoholism.
- Acute severe rapidly spreading infection.
- Pericoronitis, osteomyelitis, fracture, soft tissue wound and odontogenic infection.

Prophylactic

- More than 1/3rd are used for this purpose.
- For postoperative wound infection.
- In prevention of endocarditis in high risk patients undergoing any dental procedures that likely to cause gingival bleeding.

Inhibition of Protein Synthesis

Tetracyclines

The first member of this group called *chlortetracycline* and the second member *oxytetracycline* are derived from streptomyces species. Later in 1953, tetracycline has been prepared by catalytic hydrogenation of chlortetracycline. (Chemically, the Tetracyclines are naphthalene derivatives. The naphthalene nucleus is made up by fusion of 4 partially unsaturated cyclohexane radicals and hence the name tetracycline). Broad-spectrum bacteriostatic antibiotic was isolated from soil, i.e. Actinomycetes in 1948.

- *Action*—it inhibits protein synthesis by binding to 30S ribosomes in susceptible organism. It is effective against

a variety of gram -ve and gram +ve bacteria, rickettsial, spirochetes, protozoa, and mycoplasma. It is mainly given orally, secreted in saliva, concentrated in liver and excreted in bile. They cross placental barrier.

- *Use in dentistry*—it is used in number of dental-related conditions such as prevention of subacute bacterial endocarditis, as an adjunct to conventional periodontal therapy, for the treatment of ANUG and dental abscesses.
- *Dosage*—Tetracycline (orally 250/500 mg qid), Minocycline (orally 200 mg bid/od) and Doxycycline (orally 100 mg bid for the 1st day, with a subsequent daily dose of 100 mg OD).
- *Adverse reaction*—
 - *GIT disturbances*—it can anorexia, vomiting, heart burn, diarrhea, epigastric pain, gastroenteritis.
 - *Hepatic and renal toxicity*—there is also hepatic toxicity and renal toxicity can occur.
 - *Tooth discoloration*—hypoplasia and brown discoloration of teeth can occur; hence it is not used in 3rd trimester. All Tetracyclines are deposited in calcifying areas of the bones and teeth and may cause a yellow discoloration. Tetracyclines are not recommended for children under the age of 8 years old and pregnant women since they can permanently discolor developing teeth and alter bone growth.
 - *Increases blood urea level*—tetracycline reduces protein synthesis and has an overall catabolic effect. They induce negative nitrogen balance and can increase blood urea level.
 - *Superinfection*—Tetracyclines are the most common antibiotics responsible for superinfection.
 - *Other*—Minocycline causes dizziness, vertigo and tinnitus with high dosage. Other adverse effects, though rare, include nephrotoxicity, mild leukopenia, neurotoxicity and possibly decreased phagocytic activity.
- *Contraindication*—All tetracyclines are contraindicated during pregnancy since the drugs cross the placenta and form a stable calcium complex in bone forming tissue which can result in decrease in the fibula growth rate and retardation of skeletal development. The drug should not be given to nursing mothers since they are excreted in milk.
- *Absorption, fate and excretion*—they are not destroyed by the gastric acid or the intestinal flora. The tetracycline form insoluble complexes by chelation with calcium, magnesium, aluminium and hence substances like milk that contain calcium and antacids reduce their absorption. Administration of iron also interferes with absorption. Food also interferes with the bioavailability. The tetracycline is mainly absorbed from the duodenum and upper small intestine. Hence with larger doses, more

drugs escapes through absorption causing GIT disturbances. Tetracyclines are metabolized in the liver and metabolites are excreted mainly in the urine by glomerular filtration.

- *Properties*—Tetracyclines also have non-bactericidal properties that include anti-inflammatory, immunosuppressive properties, suppression of antibody production in lymphocytes, reduction in phagocytic function of PMNs, reduction of leukocyte and neutrophils chemotaxis, as a sclerosing agent, as an inhibitor of lipase and collagenase activity, as an enhancer of gingival fibroblast cell attachment and even at tumor activity.
- *Drug interaction*
 - *Oral contraceptive*—concurrent use of any tetracycline may render oral contraceptives less effective and may induce bleeding.
 - *Antacid*—the absorption of tetracycline from the stomach is impaired by divalent cations due to binding by the tetracycline and can decrease bioavailability. Therefore, the following should be avoided during tetracycline therapy: antacids containing aluminum, calcium or magnesium, dairy products such as milk, cheese, etc. that contain calcium and iron preparations.
 - *Penicillin*—since any bacteriostatic antibiotic may interfere with bactericidal action of penicillin, tetracycline class drugs should not be used in conjunction with any penicillin drugs.
 - *Anticoagulant therapy*—because tetracycline has proven to depress plasma prothrombin activity, patients on anticoagulant therapy (Coumarin, heparin, protamine) may require decreasing the dosage of anticoagulant drug.
 - *Methoxyflurane*—the concurrent use of tetracycline and anesthetic, methoxyflurane is contraindicated since the combination has been reported to result in fatal renal toxicity.
 - *Other drugs*—carbamazepine, Phenytoin, barbiturates, chronic ethanol ingestion may decrease the half life of tetracycline.

Macrolide

The Macrolides are a group of antibiotics that have in common macrocyclic lactone rings linked with amino-sugars. Apart from erythromycin, clindamycin, spiramycin, roxithromycin, clarithromycin and azithromycin are used clinically. Azithromycin is from a novel class of antibiotics called azalides which have been derived from Macrolides.

Erythromycin

It is isolated from streptomyces erythreus in 1952.

- **Action**—it is bacteriostatic and interferes with protein synthesis by inhibiting enzyme transferase at the 50S subunit of ribosome. It is effective against gram +ve and gram -ve bacteria. Depending upon its concentration, the antibiotic can be bacteriostatic or bactericidal. The drug is effective against penicillin resistant staphylococci.
- **Use in dentistry**—it is used as prophylactic agent against endocarditis before dental procedures and in patients allergic to penicillin. It is also used in tetanus, diphtheria and syphilis.
- **Excretion**—it is excreted through urine, faeces and bile.
- **Adverse reactions**—there may be stomatitis, abdominal pain, nausea, vomiting, jaundice, diarrhea, urticaria, and anaphylaxis. Severe adverse effects are uncommon. Hepatic dysfunction is a relative contraindication for erythromycin therapy. Super infection with Gm-ve organisms and candida may develop.
- **Dose**—it is given orally in dose of 250 to 500 mg/8 hourly.
- **Spectrum**—erythromycin has a wide range of activity against both Gm +ve facultative and anaerobic bacteria like Streptococcus, Staphylococcus, Eubacterium, Propionibacterium, bifido-bacterium, Lactobacillus and Peptostreptococcus species. However, most Gm-ve bacteria are resistant to erythromycin except Hemophilus and Neisseria species due to its inability to penetrate the lipopolysaccharide cell wall complex.
- **Absorption, fate and excretion**—the drug is partially destroyed by the gastric juice and therefore, has to be administered in the form of enteric coated tablets. The ester form, erythromycin esteolate is more resistant to inactivation by the gastric acid and is absorbed better, giving higher and more prolonged blood levels than the base. The drug can pass into fetal circulation.
- **Drug interaction**—Reduction in plasma clearance with increased plasma levels and increased toxicity when astemizole, terfenadine, theophyllin, carbamazepine, cyclosporine digoxin and warfarin are coadministered. It interferes with the action of chloramphenicol and clindamycin. Physical/chemical incompatibility between parenteral forms of erythromycin and vitamin B complex, ascorbic acid, tetracycline, heparin and phenytoin.

Other Macrolides

Azithromycin is active against Gm-ve anaerobes and provides higher drug concentrations in the tissues than in blood or serum. It has been found to be highly effective against all serotypes of Actinobacillus actinomycetemcomitans (Aa) and against Porphyromonas gingivalis. Effectiveness of erythromycin against viridans streptococci is poor. Other Macrolides, such as azithromycin and spiramycin have been used in treating dentoalveolar infections.

Azithromycin is more effective than spiramycin and might serve as an alternative antibiotic against odontogenic infections and periodontal abscess.

Aminoglycoside

- **Spectrum**—aminoglycosides are compounds that are composed of at least one sugar attached to one or more amino groups. Their main antibacterial spectrum is against Gm-ve bacilli. Some of the aminoglycoside are active against staphylococci, but most Gm +ve and most anaerobic bacteria are resistant. All are potentially ototoxic and may produce deafness due to their effect on the 8th cranial nerve.
- **Drug includes**—this group includes Streptomycin, Gentamycin, Tobramycin, Sisomycin, Kanamycin, Amikacin, Paromomycin, Framycetin and Neomycin.
- **Mechanism of action**—evidence indicates that the bactericidal effect of these drugs may be due to their ability to cause detachment of the ribosomal complex from the mRNA, which would result in the inability of the cell to produce essential proteins. The aminoglycosides are inactive under anaerobic conditions because intracellular transport is severely impaired in the absence of oxygen. Therefore, all anaerobic bacteria are markedly resistant even though they contain ribosomes that are sensitive to these antibiotics.
- **Dosage**—the dosage of these antibiotics required for clinical effectiveness is only slightly below the levels that elicit toxicity and potential adverse reactions can be serious and irreversible. Ototoxicity and nephrotoxicity have been frequently associated with use of the aminoglycoside with an incidence rate of 2-10%. Therefore, use of an aminoglycoside is somewhat limited. Due to the synergistic effect with other antibiotics, aminoglycoside are usually given in lower doses in combination with other drugs.
 - **Gentamycin**—IM/ slow IV dose (2-5 mg/kg/day in 3 divided doses) (it can produce bactericidal effect)
 - **Tobramycin**—IM/IV 3-5 mg/kg/day in 3-4 equal doses (bactericidal)
 - **Streptomycin**—0.5 to 1 gm 12 hourly for 7 days in acute infection.
- **Use**—Penicillin and Gentamycin are commonly used together for the treatment of bacterial endocarditis. Most of the aminoglycosides are only available for parenteral administration; however, some are available as creams or ointments for topical application.

Inhibitors of Cell Wall Synthesis

Penicillin

Penicillin, the most important antibiotic, was first extracted (1928) from the mould penicillium notatum. Subsequently,

a mutant of a related mould, *P. chrysogenum*, was found to give the highest yield of penicillin and is now employed for commercial production of this antibiotic. Penicillins belong to a group of antibiotics called as beta-lactams. The other members include cephalosporin, cephamycin, monobactams and carenems.

Penicillins are a family of antibiotics, with bactericidal activity against broad spectrum bacteria. The basic structure of the penicillin consists of thiazolidine ring fused with a beta lactam ring which is essential for antibacterial activity. The 2 rings constitute the fundamental nucleus of all the penicillins, namely 6-amino-penicillanic acid (6APA). Substitutions and modifications on the acyl side chain have resulted in a number of semisynthetic penicillins with enhanced antimicrobial properties such stability to gastric acids, resistance to hydrolytic enzymes and increased absorption from the stomach.

The side chain also determines the stability of the penicillin against degradation by gastric acid and by enzyme penicillinase (beta lactamase) produced by certain microorganisms. (The beta lactamase producing organisms are *Staphylococcus aureus*, *Pseudomonas*, *Enterobacter*, etc). The first identified penicillin is benzyl penicillin-G. If phenoxyacetic acid was added to the culture, phenoxy-methyl penicillin (penicillin V) was produced which is semi-synthetic one.

Classification

- *Natural penicillins*—Penicillin G (Benzyl penicillin), Procaine penicillin G and Benzathine penicillin.
- *Semi-synthetic penicillin*—
 - *Acid resistant penicillins*—phoxymethyl penicillin (Penicillin V) and Phenoxyethyl penicillin (Phenethicillin)
 - *Penicillinase-resistant penicillins*—Acid labile (Methicillin, Nafcillin, Cloxacillin, Dicloxacillin) and Acid resistant (Flucloxacillin)
- *Penicillins effective against Gm +ve and Gm-ve organisms*—Ampicillin, Amoxicillin.
- *Extended spectrum penicillins*—Carboxy penicillin (carbenicillin, Ticarcillin), Ureidopenicillins—Piperacillin, Amidinopenicillin (Mecllinam).
- *Penicillins with beta lactamase inhibitors*—Amoxicillin—Clavulanic acid (Augmentin), Ticarcillin—Clavulanic acid (Timentin).

Cloxacillin

- *Activity*—this is Penicillinase resistant penicillin. This drug has weaker antibacterial activity than penicillin G. So, it is used in conjunction with ampicillin or amoxicillin to enhance the synergism.

- *Absorption*—food interferes with the absorption of the drug. High concentration occur in kidney and liver; approximately 90 to 95% bound to plasma proteins.
- *Dosage*—the initial dose varies from 0.5 to 1 gm qid and the maintenance dose is 250 mg qid. The drug should be administered 1 hour before or 2 hours after a meal to ensure adequate absorption. It can also be given IM and by slow IV 250-500 mg 4-6 hourly.

Ampicillin

- *Action*—it is effective against Gm +ve and Gm-ve organisms. The antibacterial activity of ampicillin is generally similar to that of Benzyl penicillin, but it is more effective than benzyl penicillin against a variety of Gm-ve bacteria. The Gm +ve cocci are less sensitive to ampicillin than to benzyl penicillin. Ampicillin is inactivated by penicillinase.
- *Absorption*—it is incompletely absorbed on oral administration. Food does not interfere with its absorption. Plasma levels are reached at peak within 2 hours and 1 hour after oral and IM administration respectively.
- *Adverse effect*—ampicillin causes skin rash is usually maculopapular and not urticarial. Diarrhea is common with oral ampicillin.
- *Dosage*—the ampicillin capsule contains ampicillin hydrate equivalent to 250 mg of the base. The usual adult dose of ampicillin is 250 to 500 mg 6 hourly (qid); doses as large as 1 gm qid may be required for more refractory Gm-ve infections. High doses for IM/ IV injection are used in the treatment of meningitis and bacterial endocarditis.

Amoxicillin

- *Action*—this is effective against Gm +ve and Gm-ve organisms. This is a semisynthetic penicillin (amino-p-hydroxy-benzyl penicillin) with a broad spectrum of antibacterial activity and having substantial advantages over ampicillin.
- *Absorption*—amoxicillin is effective on oral administration and the blood levels are twice as high as those after similar dose of ampicillin. Its absorption is not affected by food. The incidence of skin rashes and diarrhea is less than with ampicillin.
- *Dosage*—250-500 mg (tid) in adult. It can also be given IV / IM.
- *Adverse reaction*—penicillins are among the least toxic of any antibiotics. Hypersensitivity is by far the most common adverse reaction noted with any penicillin. According to Idsoe et al 0.6-10% of patients treated with penicillin develop some form of allergic reactions such

as maculopapular rash, urticaria, fever, bronchospasm, vasculitis, serum sickness, exfoliative dermatitis and anaphylaxis. Mild reactions are often limited to a rash or skin lesions located on or about the head and neck that may be accompanied by facial swelling. More severe reactions may involve the joints and result in pronounced swelling or tenderness. In highly sensitized patients, anaphylaxis may occur and can result in death. IV administration has been associated with more severe reactions. Penicillin G can become more allergic after being in solution for a while, either because it breaks down to form more allergenic substances or due to the formation of high molecular weight polymers. Therefore, only freshly prepared solutions should be used. It should always be remembered that an allergy to one penicillin exposes the patient to a greater risk of reaction if another penicillin or cephalosporin is given. Broad-spectrum penicillins may alter the natural bacterial flora of the oral cavity and GIT resulting in superinfection with resistant bacteria, colonization by opportunistic pathogens, fungal infections or pseudomembranous colitis.

- **Drug interaction**—concurrent therapy of penicillin and aminoglycosides are not advised since the former may inactivate the latter.

Newer Penicillins

- **Azlocillin**—it is an acyl ampicillin antibiotic with an extended spectrum of activity and greater *in vitro* potency than the carboxy penicillins. Azlocillin is similar to mezlocillin and piperacillin. It demonstrates antibacterial activity against a broad-spectrum of bacteria, including *Pseudomonas aeruginosa* and, in contrast to most cephalosporin, exhibits activity against enterococci.
- **Dicloxacin**—it is a narrow spectrum beta-lactam antibiotic of the penicillin class. It is used to treat infections caused by susceptible Gram-positive bacteria. Notably, it is active against beta-lactamase-producing organisms such as *Staphylococcus aureus*, which would otherwise be resistant to most penicillins. It is very similar to flucloxacillin and these two agents are considered interchangeable. Dicloxacin is commercially available as the sodium salt **dicloxacin sodium** in capsules (250 or 500 mg) and injections (powder for reconstitution, 500 and 1000 mg per vial).
- **Flucloxacillin**—it is a narrow spectrum beta-lactam antibiotic of the penicillin class. It is used to treat infections caused by susceptible Gram-positive bacteria. Nowadays, it is no longer recommended against beta-lactamase-producing organisms such as *Staphylococcus aureus*, since like in other penicillins, it is not active against such infections. It is very similar to dicloxacin and these two agents are considered interchangeable.
- **Flucloxacillin** is commercially available as the sodium salt **flucloxacillin sodium**, in capsules (250 or 500 mg), oral suspensions (125 mg/5 mL or 250 mg/5 mL), and injections (powder for reconstitution, 250, 500 and 1000 mg per vial).
- **Mecillinam**—it is an extended-spectrum penicillin antibiotic that binds specifically to penicillin binding protein 2 (PBP2), and is only considered to be active against Gram-negative bacteria. It is used primarily in the treatment of urinary tract infections, and has also been used to treat typhoid and paratyphoid fever.
- **Nafcillin**—it is a narrow spectrum beta-lactam antibiotic of the penicillin class. As a beta-lactamase-resistant penicillin, it is used to treat infections caused by Gram-positive bacteria, particularly species of *Staphylococci*, that are resistant to other penicillins.
- **Oxacillin**—it is a narrow spectrum beta-lactam antibiotic of the penicillin class. It is effective against penicillinase enzymes, such as that produced by *Staphylococcus aureus*. However, resistant strains are now emerging that are called oxacillin-resistant *Staphylococcus aureus*.
- **Piperacillin**—it is an extended spectrum beta-lactam antibiotic of the ureidopenicillin class. It is normally used together with a beta-lactamase inhibitor. The combination has activity against many Gram-positive and Gram-negative pathogens and anaerobes, including *Pseudomonas aeruginosa*. Piperacillin is not absorbed orally, and must therefore be given by intravenous or intramuscular injection; piperacillin/tazobactam is administered intravenously every 6 or 8 hours; the drug may also be given by continuous infusion, but this has not been shown to be superior.
- **Ticarcillin**—it is a carboxypenicillin. It is almost invariably sold and used in combination with clavulanate. Because it is penicillin, it also falls within the larger class of beta-lactam antibiotics. Its main clinical use is as an injectable antibiotic for the treatment of gram negative bacteria, in particular, *Pseudomonas aeruginosa*. Ticarcillin is not absorbed orally, and therefore must be given by intravenous or intramuscular injection. The usual adult dose of Ticarcillin is 3.5 gm four times a day.

Cephalosporins

In 1945, Prof. G. Brotzu isolated a fungus called as *Cephalosporium acremonium*. Cephalosporins are extracted from this fungus. Cephalosporins have 7-amino cephalosporanic acid nucleus which bears close resemblance to the 6-APA nucleus of penicillins.

- **Antibacterial activity**—cephalosporins possess a wide range of activity against Gm +ve and Gm-ve bacteria. Cephalosporins act by inhibiting bacterial cell wall synthesis and are bactericidal.

- *Absorption, fate and excretion*—cephalosporins are administered either orally or IV (IM is painful). Cephalosporins are eliminated mainly by renal excretion (As with penicillins, renal tubular blocking with probenecid increases the plasma levels significantly).
- *Adverse reaction*—it can cause allergy such as skin rashes, fever, serum sickness, anaphylactic reaction (Rare), eosinophilia, neutropenia, transient splenomegaly and increased SGOT levels. Some of the newer cephalosporins cause disulfiram like effect when combined with alcohol.
- *First generation cephalosporins*—the first cephalosporin introduced into medical practice was cephalothin. This compound is active against both penicillin-sensitive and resistant staphylococci, pneumococci, streptococci and the common Gm-ve pathogens, but they are not effective against anaerobes. Other 1st generation cephalosporins are cephacetrile and cefazolin. The 1st orally active cephalosporin for medical use was cephaloglycin. Cephalexin is more stable and has better oral absorption. It is often used as follow-up therapy and for the treatment of minor infections involving Gm+ve organisms. Cephradine has a similar Gm+ve spectrum, but is more active against Gm-ve organisms.
- *Second generation cephalosporins*—these offer a wide range against Gm-ve bacilli. Their main use would appear to be in the Gm-ve infections, especially those caused by β lactamase producing organisms. But they have less activity against most pathogens that cause infection of wounds.
- *Third generation cephalosporins*—they have poor activity against the Gm+ve cocci; but are more active against Gm-ve bacilli than the first and second generation cephalosporins. This generation includes ceftazidime, cefsulodin, ceftriaxone (once a day).
- *Fourth generation cephalosporins*—Cefepime is more resistant to some β lactamase. It is active against streptococci, and methicillin-sensitive staphylococci. Its main use is in serious Gm-ve infections including infections of the CNS into which has excellent penetration. Dose: 2 gm IV bid.
- *Fifth generation cephalosporins*—this is recently discovered cephalosporin and it is used in severe infection. Example of this generation cephalosporin is ceftobiprole.
- *Cefazolin*—parenteral administration results in higher blood level that persists longer. It has a half life of 2 hours due to slower tubular secretion. Dose—0.25 gm 8 hourly (mild cases), 1 gm 6 hourly (severe cases) IM and IV.
- *Cephalexin*—it is effective against most gram +ve cocci, bacilli, *E. coli* and *Klebsiella*. It is an orally effective first generation cephalosporin. Dose—0.25 to 1 gm 6-8 hourly and in children 25-100 mg/kg/day.
- *Cefadroxil*—it is close congener of cephalexin, has good tissue penetration and it exerts more sustained action at the site of infection. Dose—0.5 to 1 gm BD.
- *Cefaclor*—it retains significant activity by the oral route. It is more active *H. influenzae*, *E. coli*. Dose—125 to 250 mg daily.
- *Cefuroxime*—it is highly active against ampicillin resistant *H. influenzae*. It is well tolerated by the IM route and attains relatively higher CSF level. Dose—0.75 to 1.5 gm IM 8 hourly.
- *Cefixime*—it is an orally active and is highly active against enterobacteria. Dose—200 to 400 mg BD.
- *Ceftobiprole*—the adult dose of ceftobiprole is 500 mg every eight hours given intravenously. Ceftobiprole cannot be given by mouth. Ceftobiprole is not licensed to be used in children.

Interference with Cell Membrane Structure

5

The selective permeability of the cytoplasmic membrane allows the bacterial cell to control the entry and exit of substances by specific transport mechanisms. This membrane is associated with a number of vital cell functions such as DNA replication and cell wall synthesis. Any agent that adversely affects the function of this membrane is usually lethal for the cell. Unfortunately, the antibiotics that exert their effect against the cell membrane do not exhibit selective toxicity and are equally destructive to both bacterial and mammalian cells.

Two general classes of antibiotics belong to this category, 1) the Polymyxins, which are antibacterial and 2) the Polyenes, which are primarily used against fungi and yeasts. Due to this host toxicity, these are used only in cases of Gm-ve bacteria resistant to multiple antibiotics. The Polyenes are a group of large, structurally related compounds that have no antibacterial activity, except some members of the genus *Mycoplasma*, but are highly active against yeasts and fungi. Polyenes act on sensitive fungi by binding to sterols of the plasma membrane resulting in alteration of membrane permeability and leads to the leakage of essential metabolites and eventually cell death.

Large Polyenes such as amphotericin B and nystatin exhibits 2 types of sterol binding, separable into fungistatic and fungicidal. The first is reversible and is associated with inhibition of growth and increased permeability of the membrane resulting in the loss of potassium from the cell. The second occurs at high drug concentrations, is irreversible and leads to cell death.

Mammalian cells due to the presence of cholesterol in their membranes are also subject to the action of Polyenes. This accounts for the very toxic and numerous side effects

associated with systemic polyene therapy such as headache, fever, chills, muscle and joint pain, nausea, vomiting, nephrotoxicity, neurotoxicity, hepatotoxicity, allergic reactions, etc.

Parenteral administration is only indicated in the treatment of serious infections. Amphotericin B is available as a lotion, cream or ointment for the treatment of cutaneous candidal infections and as lozenges for the treatment of oral candidiasis. Nystatin paint or lozenges can also be used for local application against candidal infections.

Interference with Nucleic Acid Synthesis

Several antimicrobial agents preferentially inhibit either DNA or RNA synthesis and most of them do not exhibit selective toxicity. However, nitroimidazole and quinolones do exhibit selective toxicity and are clinically useful in the treatment of certain bacterial infections.

Nitroimidazoles

- *Drugs include*—members of the nitroimidazole group of antibiotics include Metronidazole, Nimorazole, Tinidazole, Secnidazole and Ornidazole.
- *Mechanism of action*—the mechanism of action of these antibiotics is not clear. Since the drugs are only active against anaerobic organisms, it was first postulated that the drug interacted with biochemical pathways are found only in obligate anaerobes. This theory has been replaced, since current evidence indicates that these drugs interact with bacterial DNA. Upon entry into an anaerobic organism, metronidazole is reduced at the 5-nitro position producing a number of short-lived cytotoxic intermediates which react with DNA, resulting in cell death. The reductive pathways are characteristic of sensitive anaerobic bacteria and protozoa but are not present in aerobic bacteria. The reported carcinogenicity of this drug in rodents may be related to the fact that mammalian liver microsomes can reduce metronidazole.
- *Use in dentistry*—its primary use is in the treatment of obligate anaerobes associated with the oral cavity, intestinal and female genital tracts. Metronidazole has been used successfully in the treatment of periodontitis which is probably related to its high activity against the Gm-ve anaerobic bacilli that are often associated with the disease. The concurrent oral administration of metronidazole with either amoxicillin or Augmentin has been used with some success in the treatment of both juvenile and adult forms of periodontitis and also effective in the treatment of *A. actinomycetemcomitans*—associated periodontitis.

- *Absorption, fate and excretion*—metronidazole is rapidly and almost completely (80%) absorbed from the small bowel and very little reaches the colon. Food does not affect its bioavailability. The drug is metabolized mainly in liver. The metabolites are excreted mainly in the urine, imparting a deep red-brown color to it. The drug crosses the placental barrier and is present in the milk.
- *Adverse reaction*—nausea, anorexia, abdominal pain and metallic taste in mouth are common. Concurrent consumption of alcohol along with metronidazole causes antabuse like reactions due to accumulation of acetaldehyde in the blood. Metronidazole affects the activity of hepatic enzymes involved with the metabolism of ethanol and acetaldehyde. Possible tumorigenic effects are seen in experimental animals but not in clinical practice (But it should not be given to pregnant women or nursing mothers). The most severe, but rare reactions have been epileptic seizures and peripheral neuropathy.
- *Drug interaction*—alcoholic beverages should not be consumed during therapy with metronidazole for at least one day afterward, since abdominal cramps, nausea, vomiting, headache and flushing may occur. Toxic psychosis has been described when the drug has been administered to alcoholics receiving disulfiram within the last two weeks due to the possibility of psychotic reactions. Metronidazole potentiates the anticoagulant effect of warfarin and other oral coumarin anticoagulants.
- *Dosage*—Metronidazole (tablets—200/ 400 mg tid, IV—500 mg tid, Tinidazole, Secnidazole and Ornidazole have got longer half life (Dose: 500 mg bid for periodontal infections).

Quinolones

- *Drugs include*—the quinolones constitute a group of 1, 8-naphthyridine derivatives. These are synthetically produced drugs and therefore are not true antibiotics. Nalidixic acid was introduced into clinical use in 1964 and is the prototype of the quinolones drugs. Ciprofloxacin, a fluorinated quinolones carboxylic derivative is an example of the newer drug/2nd generation drug. Others in this group include Norfloxacin, Ofloxacin, Pefloxacin, Amifloxacin, Lomfloxacin, Levofloxacin, and Gatifloxacin.
- *Mechanism of action*—Nalidixic acid and Ciprofloxacin are generally considered bactericidal, since they inhibit the bacterial DNA replication (The bactericidal effect can only occur in the presence of competent RNA and protein synthesis. The imbalance of inhibited DNA replication and continuing protein synthesis results in inhibition of cell division). The site of inhibition is a

specific enzyme, DNA gyrase. This enzyme is responsible for the coiling of the long bacterial chromosome so that it fits into the bacterial cell, but still maintains its spatial arrangement. Quinolones interfere with this gyrase so that the spatial arrangement of the DNA is not possible and therefore it cannot be transcribed.

- **Ciprofloxacin**—ciprofloxacin is the 1st oral broad-spectrum antimicrobial agent with good activity against *Pseudomonas aeruginosa*. It has an excellent activity against a wide range of Gm-ve organisms, including many that are resistant to 3rd generation cephalosporins, broad-spectrum penicillins and the newer aminoglycosides. It also has good activity against Gm+ve bacteria and is thus useful in the management of mixed infections. However, most anaerobic bacteria are resistant. The newer quinolones may not be used routinely by dental professionals due to resistance encountered with the oral flora. Fortunately ciprofloxacin does not cross-react with most antibiotics. Infact, an additive effect has been reported with some antibiotics such as the β lactams, aminoglycosides, clindamycin and metronidazole.
- **Adverse reaction**—in comparison to other antibiotics, most quinolones are well tolerated. Nausea, headache, vomiting, diarrhea, photosensitivity, skin rashes, etc. are rarely seen. Ciprofloxacin is excreted in breast milk and may cross the placental barrier. Therefore, it should not be given to pregnant women or nursing mothers except in the case of severe infections. The quinolones are not recommended for pre-pubertal children.
- **Drug interaction**—quinolones inhibit the metabolism of theophylline and caffeine. Toxicity may occur due to the inhibitory effect of ciprofloxacin on theophylline if given together. Concurrent administration with antacids containing magnesium, Al, Ca, Zn containing multivitamins or iron containing preparations may substantially interfere with absorption of ciprofloxacin. Quinolones enhance the effect of warfarin and other oral *anti-coagulants*. It must be remembered that organisms do develop resistance to them and also since it is costly, their routine use in all infections is to be discouraged.
- **Dosage**—Ciprofloxacin (250/ 500 mg bid orally, 200/ 400 mg IV bid over 30-60 minutes), Ofloxacin (200-400 mg OD orally in the morning preferentially, 200-400 mg IV bid/ OD), Lomefloxacin (400 mg OD orally, 400 mg IV), Pefloxacin (400 mg bid orally, 400 mg IV bid over 1 hour), Sparfloxacin (200-400 mg OD/ bid orally).

Topical Antiseptic and Antibiotics

There are sufficient data to consider the species *Actinobacillus actinomycetemcomitans* (Aa), *Tannerella*

forsythensis and *Porphyromonas gingivalis* as key periodontal pathogens, whereas bacteria like *Prevotella intermedia*, *Campylobacter rectus*, *Peptostreptococcus micros*, *Fusobacterium nucleatum*, *Eubacterium nodatum*, *Streptococcus intermedia* and *Spirochetes* have shown moderate evidence for causation. Recent findings have associated yeasts, staphylococci, enterococci, pseudomonas, various enteric rods or some herpes viruses (Cytomegalovirus and Epstein-Barr virus type I) with destructive periodontal disease.

The clinical improvement after periodontal therapy indeed correlates directly with the degree to which pathogenic subgingival species are reduced or eradicated. To achieve reduction or elimination of pathogens, a subgingival application of antiseptics or antibiotics has often been considered.

Classification of Local Antimicrobial Therapy

Systemic antimicrobial agents enter periodontal pockets following their intestinal absorption and passage from the bloodstream into oral tissues, GCF and saliva. Systemic delivery provides a ready exposure of all periodontal sites to the antimicrobial agent, but it also poses a risk of adverse reactions to non oral body sites. Local antimicrobial therapy in periodontitis involves direct placement of an antimicrobial agent into subgingival sites, minimizing the impact of the agent on non-oral body sites. They are applied as a part of home oral hygiene regimens and professionally applied as part of office based treatment procedures. Local delivery may be further classified as providing either non-sustained or sustained subgingival drug delivery. Sub-gingival irrigation with antiseptic agents lacking substantively of oral tissues (Povidone-iodine) are examples of non-sustained drug delivery. Sustained or controlled drug release can be provided with sub gingival irrigation of agents intrinsically substantive for tooth root surfaces (aqueous tetracycline) or pocket placement of commercial antimicrobial fibers, gels or films.

- **Personally applied (Home self-care)**—Non-sustained subgingival drug delivery (Home oral irrigation) and sustained subgingival drug delivery (None developed to date).
- **Professionally applied (Dental office)**—Non-sustained subgingival drug delivery (Professional pocket irrigation) and Sustained subgingival drug delivery (Controlled-release device)

Agents that exert bactericidal effects within 5 minute time period are preferable for sub-gingival irrigation. Iodine showed 5 minute bactericidal action against the test organisms at concentrations therapeutically attainable at

Summary chart of antibiotics which are most commonly used in dentistry

Drug	Trade names	Dosage form	Dose	Indications	Contraindications	Adverse effects
Tetracycline	Achromycin, Terramycin	Capsule Injection Ointment	1-2 gm daily divided into 4 doses	Juvenile periodontitis, Chronic periodontal disease, Refractory periodontitis, Desquamative gingivitis	Pregnancy, children below 8 years	GI disturbance, tooth discoloration, enamel hypoplasia
Clindamycin	Clincin Dalcap	Tablet Capsule Injection	150-300 mg 6 hourly	Anaerobic streptococci, Clostridium infections, Refractory periodontitis	Hypersensitivity, infancy	Urticaria, diarrhea, abdominal pain, jaundice, liver abnormalities
Erythromycin	Althrocin Erythrocin E. mycin	Tablet	250-500 mg 8 hourly	Refractory periodontitis	Hypersensitivity	Mild epigastric pain, diarrhea, allergic reaction
Metronidazole	Flagyl Metrogyl Aldezole	Tablet Suspension injection	200-400 mg TDS. 200 mg/5 ml	Ulcerative gingivitis, periodontitis, ANUG	Neurological disease, blood dyscrasias, pregnancy	Anorexia, nausea, metallic taste, glossitis
Quinolone Ciprofloxacin	Ciplox Cipin	Tablet, injection	250-500 mg 12 hourly	Osteomyelitis, ANUG, joint infection, recurrent periodontitis	Hypersensitivity, children and elderly	Diarrhea, vomiting, abdominal pain, arthritis, restlessness
Penicillin Amoxicillin Ampicillin	Kaypen Ampilin Amox Mox	Capsule, Syrup	250 mg-1 gm TDS 125 mg/ml	Refractory periodontitis	Sensitivity Pregnancy	Skin rash, urticaria, GIT upset, diarrhea
Cephalosporin Cefotaxime Cefaclor Cefixime	Alcephin Biotax,	Capsule Injection Syrup	2-6 gm daily in 2-3 divided dose 4 gm initially followed by 2 gm IV	Inhibits growth of gram—ve anaerobes, Osteomyelitis	Hypersensitivity, renal failure	GIT upset, allergic reaction, increased SGPT, candidiasis
Chlorhexidine	Hexidine Rexitin	Suspension	0.2% w/v 100 ml	Oral hygiene bacterial infection	Allergy to chlorhexidine	Burning sensation, candidiasis, bad taste sensation, staining of teeth

subgingival sites (0.25-0.5%). But chlorhexidine needs (0.5-2%) and stannous fluoride needs (0.5-20%) 5 minutes for bacterial action. Metronidazole and amoxicillin required microbial contact time of 60 minutes or more for bactericidal activity. Interestingly, the bactericidal effects of povidone-iodine and of bicarbonate are potentiated by H_2O_2 . Chlorhexidine may be inactivated in periodontal pockets via binding to serum proteins, which are markedly elevated in GCF.

The other topical antimicrobial agents are : 1.64% SnF_2 gel, 3% H_2O_2 , 1% Chloramine-T, 1.25% amine fluoride gel, sodium bicarbonate tooth powder, and povidone-iodine etc.

Dose Calculation

Children Dose can be calculated by following formulas

$$\text{Young's Formula} = \frac{\text{Age} \times \text{Adult Dose}}{\text{Age} + 12}$$

$$\text{Clarke's Formula} = \frac{\text{Body Wt (kg)} \times \text{Adult Dose}}{150}$$

Prophylactic Antibiotics

According to AHA (American Heart Association, 2002)

- *Orally*—Amoxicillin 2 gm one hour before surgery. Children—50 mg/kg body wt. one hour before surgery.
- *IV or IM*—Ampicillin 2 gm half an hour before surgery. Children—50 mg/kg body wt. half an hour before surgery.
- *If allergic to penicillin*—Clindamycin 600 mg, children—50 mg/kg body wt. If Orally one hour before surgery, If IV or IM half an hour before surgery.

Others	Adult	Children
Clarithromycin	500 mg	15 mg/kg body wt.
Azithromycin	500 mg	15 mg/kg body wt.

41

Analgesic and Anti-inflammatory Drugs

Introduction

In dentistry most common complaint of the patient is pain. So management of pain with the analgesic is primary importance of dentist. Pain is ill-defined, unpleasant sensation usually evoked by external or internal noxious stimulus. Pain receptors are mainly the free nerve ending widely spread in superficial layer and deep into the body. Certain pain receptors are present in the body called as chemoreceptor like bradykinin, prostaglandin (PG), prostacyclin (PGI₂), thromboxane (TXA₂), histamine, acetylcholine and proteolytic enzymes elicit pain after tissue injury. A delta fiber transmits fast-acute pain whereas c-fibers transmit slow-chronic type of pain.

Definition of Analgesic

Analgesics are the drugs that selectively relieve pain by acting in CNS or on peripheral pain mechanisms, without significantly altering consciousness. Transmitters involved in analgesic system are enkephalin and serotonin.

Classification (Fig. 41-1)

Nonselective COX inhibitors (Conventional NSAIDs)

- *Salicylates*—Aspirin, Calcium carbaspirin, Choline salicylates.
- *Propionic acid derivatives*—Ibuprofen, Naproxen, Ketoprofen, Flurbiprofen, Oxaprozin.
- *Anthranilic acid derivative*—Mephenamic acid.
- *Aryl acetic acid derivative*—Diclofenac.
- *Oxicam derivative*—Piroxicam, Tenoxicam.
- *Pyrrolopyrrole derivatives*—Ketorolac.
- *Indole derivative*—Indomethacin, Sulindac, Tolmetin, Etodolac.

- *Pyrazolone derivatives*—Phenylbutazone, Oxyphenbutazone.

Preferential COX-2 inhibitors

- Nimesulide, Meloxicam, Nabumetone.

Selective COX-2 inhibitors

- Celecoxib, Rofecoxib, Valdecoxib, Etoricoxib.

Analgesic-antipyretics with poor anti-inflammatory action

- *Para-aminophenol derivative*—Paracetamol (Acetaminophen)
- *Pyrazolone derivative*—Metamizol, Propiphenazone.
- *Benzoxazocine derivative*—Nefopam.

Fig. 41-1: Types of analgesics

General Principles of Use of Analgesics

- *Treat the cause of pain*—where possible, identify and treat the cause of pain.
- *Psychological management*—relieve the factors which lower the pain threshold (fatigue, anxiety and depression).
- *Regular analgesia*—chronic pain requires regular analgesia.
- *Simple analgesics*—use simple analgesics initially.
- *Do not use multiple drug*—avoid polypharmacy.

Nonselective Cyclo-oxygenase Inhibitors/Nonsteroidal Anti-inflammatory Drugs

NSAIDs mainly block the PG generation. PG is the substance which is produced from arachidonic acid by the enzyme cyclo-oxygenase (COX) which exist in a constitutive (COX-1) found in blood vessels, stomach and kidney; and an inducible form which is induced at the site of inflammation by cytokines and other inflammatory mediators. *Prostaglandin* play a part in the erythema, edema, and fever associated with inflammation and generate the pain either by its direct action or by sensitizing the pain receptors or by release of substance by tissue damage such as bradykinin and histamine. NSAIDs inhibit the action of cyclo-oxygenase (COX-1 and COX-2) enzyme. It interfere with the synthesis of prostaglandin and hence, causes the blockage of impulse generation mediating pain.

Nabumetone, a new NSAIDs preferentially inhibit COX-2. Similarly, newer drugs like Nimesulide and Meloxicam are also reported to have greater affinity for COX-2 as compared to COX-1.

Action of NSAIDs

- **Analgesic action**—NSAIDs do not affect the tenderness which is induced by direct application of PG, but it blocks the pain sensitizing mechanism induced by bradykinin, tumor necrosis factor Alfa, interleukins and other algesic factors. It is used in dental caries and postextraction pain.
- **Antipyretic action**—fever during infection is produced due to generation of pyrogens which induces the PG production. Hence, NSAIDs are used to block the action of pyrogens and help to reduce the body temperature in fever.
- **Anti-inflammatory**—PG are only one mediator of the inflammation. NSAIDs is considered to be inhibition of PG synthesis at the site of injury. Anti-inflammatory potency of different compounds correspond with their potency to inhibit COX. However, Nimesulide is a potent anti-inflammatory but weak COX inhibitors.
- **Dysmenorrhea**—PG synthesis in endometrium causes uncoordinated uterine contraction with compressed blood vessel results in uterine ischemia and pain. NSAID decrease PG synthesis and relieves the pain approximately 70%. It also relieves additional symptoms like headache, muscle ache and nausea.
- **Antiplatelet Function/Bleeding**—Platelet aggregation is due to TXA₂. NSAIDs inhibit TXA₂. NSAIDs acetylates COX present in platelets when they are in portal circulation, before it get acetylated in liver.

- **Closure of ductus arteriosus**—PGE₂ and PGI₂ produced in ductus arteriosus, kept it patent during fetal life. At the time of birth, it get closed as in the normal mechanism. But in case if it is failed to close during birth, small dose of indomethacin or aspirin induce its closure by inhibiting PG. But it should be avoided in pregnancy, as it may cause premature closure. So indomethacin and Aspirin is contraindicated during pregnancy.
- **Gastric mucosal damage**—Cyclo-oxygenase-1 (COX-1) has physiological role like protection of gastric mucosa by secretion of mucous. NSAID other than selective COX-2 inhibitor which may inhibit COX-1 cause gastric irritation and gastric ulceration due to reduced mucous and HCO₃ secretion. They induce back diffusion of H⁺ ions in gastric mucosa also. Paracetamol has weak inhibition of COX and selective COX-2 inhibitor do not cause gastric mucosal damage.
- **Renal effect**: COX-1 dependent impairment of renal blood flow and reduction. COX dependent Na and H₂O retention. Renal efferent is more significant in CHF, hypovolemia, hepatic cirrhosis.
- **Anaphylactic reaction**—aspirin precipitated asthma, angioneurotic swelling and urticaria or rhinitis in some individuals. Asthma is due to imbalance between constrictor PG (PGD₂), TXA₂, LT and dilators PG (PGE₂, PGI₂).

Salicylates

Aspirin

Aspirin is acetylsalicylic acid. It is rapidly deacetylated in body by acetylating other macromolecule like COX in platelet, before platelet get deacetylated in liver as physiologically happened. Acetylated platelet reduce tendency to aggregate and induce bleeding tendency due to aspirin. It is developed by Bayer in 1899. This includes species of willow. Salicylates derived from salix, a Latin name willow tree.

Mechanism of Action for Therapeutic Use (Fig. 41-2)

It acts both centrally but peripheral effect is main. It has therapeutic action of analgesic and antipyretic at low dose. At high dose anti-inflammatory action.

- **Analgesic and anti-inflammatory action**—its analgesic and anti-inflammatory action is due to prevention of PG (mainly PGE₂) mediated activated nerve ending. PG is associated with pain and fever related to inflammation and activates receptors released by tissue damage like bradykinin and histamine. They are chemical pain mediators. Aspirin reduce PG secretion, so it has

Fig. 41-2: Mode of action of non-narcotic analgesics

antipyretic and analgesic effect by inhibiting COX pathway by acetylating active site of COX and hence PG and TXA_2 . Its action is irreversible. It also blocks peripheral pain impulse generation. It has same action on subcortical site like thalamus and hypothalamus. Bradykinin and histamine brings inflammatory action during tissue damage (e.g. pulpitis), these chemicals are inhibited by Aspirin, and so it explains its anti-inflammatory action. Dose: Analgesic dose- 0.3-0.6gm for headache, toothache, joint pain, dysmenorrhea. Anti-inflammatory dose—3-5 g/day.

- **Antirheumatic action**—Bradykinin and prostaglandin cause vasodilatation, increase in capillary permeability which is sign of inflammation and inflammatory changes. These chemical mediators are inhibited by Aspirin which is demonstrated as an antirheumatic agent. It also prevents the release of lysosome which destroys cartilage of rheumatic joints. Dose- 3-5 g/day
- **Antipyretic action**—temperature regulating center present at hypothalamus during infection pyrogens directly act on hypothalamic integrating center (thermostat) causing fever. PGE_2 is also involved in this process. Aspirin reduces temperature by profuse sweating and synthesis of PGE in hypothalamus.
- **Antiplatelet effect**—therapeutically used in cerebral or myocardial infarction. Action of platelet is due to thromboxane produced during cyclooxygenase pathway in nucleated platelets causing aggregation of platelets in constricted vessel wall. Aspirin has antiplatelet action as it causes acetylation of COX in nucleus of platelet and reduces thromboxane synthesis. Hence non-nucleated, acetylated platelet irreversibly loses its aggregatory properties. Dose: 60-100 mg/day.
- **Other uses**—After birth, if ductus arteriosus is kept patent due to elaboration of prostaglandin. So, NSAIDs bring about closure of ductus within a few hours by inhibiting PG production.

Uses

- **As an analgesic**—for headache, backache, myalgia, joint pain, toothache, neuralgia, in low dose of 0.3-0.6 gm, 6-8 hourly.
- **As an antipyretic**—effective in the any kind of fever.
- **Acute rheumatic fever**—it is the first drug to be used in the dose of 4-6 gm or 75-100 mg/kg/day. It brings out marked symptomatic relief in 1-3 days and maintenance dose of 50 mg/kg/day continued for 2-3 weeks until all the signs of active disease disappear. Withdrawals of drug should be gradual over the next 2 weeks.
- **Rheumatoid arthritis**—Aspirin in the dose of 3-6 gm/day is effective producing relief of pain, swelling and morning stiffness.
- **Osteoarthritis**—it affords symptomatic relief only. It is used only when required.
- **Postmyocardial infarction**—as Aspirin inhibits the platelet aggregation, it lowers the incidence of reinfarction. It is used in the dose of 100-300 mg Aspirin/day for 12 weeks, reduces the transient ischemic attacks.
- Patent ductus arteriosus.

Adverse Effects

- **Peptic ulceration**—COX-1 has physiological role in gastrointestinal tract like mucus secretion for protection of gastric mucosa. Aspirin is COX inhibitor, it decreases mucus secretion from gastric mucosa by inhibiting cyclooxygenase. Treatment: Misoprostol (PG analog) is used to heal these ulcers.
- **Precipitation of asthma**— PGD_2 , TXA_2 are bronchoconstrictors while PGE_2 and PGI_2 are dilators. Aspirin causes imbalance between these constrictors and dilators causing precipitation of asthma.
- **Hemorrhage**—treatment is vitamin K supplements.
- **Salicylism**—large dose (3-5 g/day is anti-inflammatory dose) results in headache, dizziness, tinnitus, confusion, vertigo, reversible impairment of hearing and vision, sweating, palpitation and hyperventilation. These syndromes are known as salicylism.
- **Reye's syndrome**—use of Aspirin in children below 12 years with influenza or chickenpox cause life-threatening condition characterized by vomiting, lethargy, delirium, coma and even death. If a person survives, it causes irreversible brain damage. Use of Aspirin in children is prohibited in India.
- **Acute salicylates poisoning**—10-30 g is the suicidal dose of Aspirin in adults. In children, 4 ml is the fetal dose. Toxicity is seen with serum salicylates level more than 50 mg/dl.
- **Clinical feature**—vomiting, dehydration, electrolyte imbalance, acidotic breathing, abdominal pain, anorexia. In severe cases, CNS abnormalities and skin eruption, hyperpyrexia, restlessness, vertigo, tremors,

hallucination, convulsion and coma and even death due to respiratory failure and cardiovascular collapse may occur. Severe hypoglycemia may be seen in children.

- *Treatment*—gastric lavage to remove unabsorbed drugs, alkalization, diuresis. Activated charcoal is used to reduce absorption of salicylates from gut alcohol and adequate amount of intravenous fluid for dehydration. Bicarbonate solutions for alkaline diuresis. Glucose IV for ketosis and hypoglycemia. Blood transfusion or vitamin K for hemorrhage.

Contraindication

- *Peptic ulcer*—in peptic ulcers, bleeding tendencies.
- *Pregnancy*—in pregnancy, it causes premature closure of ductus arteriosus, delayed and prolonged labor, greater postpartum blood loss, low birth weight babies.
- *Nursing mother*—it is not used in breastfeeding mothers.
- *G6PD deficiency*—it causes hemolysis.
- *Before dental extraction*—it should be stopped 1 week before dental extraction or any major surgeries.
- *Chronic liver disease*—it may cause hepatic necrosis.
- *Diabetes*—Aspirin has hypoglycemic action.
- *Hepatic damage*—in hepatic damage, vitamin K deficiency or hemophilia, hypoprothrombinemia.
- *Chicken pox*—in children suffering from chicken pox or influenza—due to risk of Reye's syndrome in pediatric patient.

Pharmacokinetics

Aspirin absorbed from stomach and small intestine. Approximately 80% plasma protein binding capability. Half life at therapeutic dose is 15-20 mins, at anti-inflammatory dose is 8-12 hours and during poisoning 30 hours.

Drug Interaction

- It increases toxicity of oral anticoagulants, heparin, naproxen, oral antidiabetics, phenytoin, thiopental, indomethacin, valproic acid, and methotrexate.
- It decreases action of probenecid and sulfinpyrazone (uricosuric action)
- Ascorbic acid and ammonium chloride increase action of Aspirin
- Sodium bicarbonate decreases action of Aspirin
- It increases action of antiplatelet drugs
- Phenobarbital decreases aspirin action
- Aspirin decreases beta blocker's action
- In patient taking Aspirin, gastrointestinal bleeding increases by steroids, alcohol, indomethacin, and pyrazolon and anti-inflammatory drug. Furosamide increases Aspirin precipitation by decreasing salicylates excretion.

- Aspirin increases insulin and sulfonylureas.
- Antacid and activated charcoal decrease Aspirin absorption.

Trade Name

T. Aspirin 350 mg, T. Ecosprin 75, 150, 325 mg, T. Disprin 35 mg, T. Loprin 75 mg.

Propionic Acid Derivative

Ibuprofen

- *Action*—analgesic, antipyretic, anti-inflammatory.
- *Use*—analgesic (Dose—400 mg/TDS), antipyretic, anti-inflammatory. It is used in rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, dental inflammation and other musculoskeletal disorders.
- *Adverse effects*—they are less than Aspirin. Gastric discomfort, nausea and vomiting. Headache, dizziness, blurring of vision, tinnitus and depression may occur. It precipitates aspirin-induced asthma.
- *Contraindication*—bronchial asthma, pregnant and lactating women, and peptic ulcer.
- *Pharmacokinetics*—99% bound to plasma protein, $t_{1/2}$ is 2 hours and it can cross blood-brain barrier, placenta.
- *Drug interaction*—it aggravates action of Aspirin, antiplatelet agent. It decreases action of diuretic and anti-hypertensive, e.g. beta blocker, thiazide.
- *Preparation*—T. Brufen 400, 200, 600, 800 mg. Ibugesic 100 mg/5 ml suspension.

Naproxen

- *Plasma $t_{1/2}$* —12-15 hours
- *Dose*—250 mg BID after meal
- *Trade name*—T. Naprosyn 500 mg, T. xenobid 250 mg.

Flurbiprofen

- *Action*—it suppresses both PGE₂ and PGE₂ alpha by cyclo-oxygenase enzyme. It inhibits leukocyte migration, 99% plasma protein binding.
- *Use*—as an anti-inflammatory in ocular infections—OCUFLUR (0.03%) eyedrop, 1 drop 6 hourly.
- *Trade name*—T. Arflur 50, 100 mg, T. Flurofen 100 mg. Ocuflur 0.03% eyedrop.

Anthranilic Acid

Mephenamic Acid

- *Action*—analgesic, antipyretic, anti-inflammatory in action.
- *Use*—as an analgesic primarily in muscles, joints and soft tissue pain. It is quite effective in dysmenorrhea. It may be useful in rheumatoid arthritis and osteoarthritis.

- *Pharmacokinetic*—Plasma $t_{1/2}$ 2-4 hours, absorbed slowly from gut.
- *Dose*—500 mg TDS
- *Adverse effect*—diarrhea, dizziness, rashes, hemolytic anemia, agranulocytosis, thrombocytopenic purpura, megaloblastic anemia.
- *Contraindication*—gastrointestinal ulceration, impairment of renal function.
- *Trade name*—C. Medol 250, 500 mg, T. Meftal 250, 500 mg, T. Ponstan 250 mg.

Aryl-Acetic Acid Derivative

Diclofenac

- *Action*—as an inhibitor of COX, it is analgesic, antipyretic, anti-inflammatory drug.
- *Plasma half-life*—2 hrs.
- *Indication*—rheumatoid arthritis, osteoarthritis, bursitis, post-traumatic and post-operative inflammation and ankylosing spondylitis.
- *Dose*—100-200 mg BID or TDS.
- *Trade name*—T. Diclomax 25, 50, 100 mg; Voveran IM 75 mg; T. Voveran 50 mg.
- *Adverse effect*—epigastric pain, nausea, headache, dizziness, rashes. Kidney damage is rare.

Oxicam Derivatives

Piroxicam

- *Action*—it reversibly inhibits COX, so it has analgesic, antipyretic, anti-inflammatory properties.
- *Plasma half-life*—2 days
- *Adverse effect*—heart burn, nausea, anorexia.
- *Indication*—rheumatoid and osteoarthritis, ankylosing spondylitis, postextraction pain, pulpitis in dentistry.
- *Dose*—20 mg BD for 2 days followed by 20 mg OD.
- *Trade name*—C. Pirox 10, 20 mg, C. Pirox 10, 20 mg. Tenoxicam: T. Tabitil 20 mg Dose: 20 mg OD. T. Dolonex.

Pyrrolo-pyrrole Derivative

Ketorolac

- *Action*—it also inhibits PG and relieves pain by peripheral mechanism.
- *Half-life*— $t_{1/2}$ 5-7 hour.
- *Indication*—Postoperative, dental and acute musculoskeletal pain, pain due to bony metastasis, migraine.
- *Adverse effect*—nausea, abdominal pain, ulceration, loose stools, drowsiness, pain at injection site, dizziness.
- *Dose*—Dose: 10-20 mg tablets 6 hourly. 15-30 mg IM or IV every 4-6 hours

- *Trade name*—T. Ketorol 10 mg, T. Toralac 10 mg, T. Ketanov 10 mg.

Preferential COX-2 Inhibitors

Nimesulide

- *Action*—it has weak inhibition of PG synthesis but action on COX-2 selectively, has potent anti-inflammatory action by inhibition of histamine release.
- *Use*—postoperative dental pain, dysmenorrhea, inflammation of the ear and throat.
- *Adverse effect*—nausea, loose motion, rash, pruritus, dizziness, hepatic failure.
- *Pharmacokinetic*—99% plasma protein binding
- *Plasma half life*—2-5 hours
- *Dose*—100 mg BID
- *Trade name*—T. Nimulid 100 BD, T. Nimegesic, T. Nimodol.

Para-amino Phenol Derivative

Paracetamol

- *Action*—it is de-ethylated active metabolite of phenacetin. It has analgesic-antipyretic action but no anti-inflammatory action. It has poor inhibition of PG, poor ability to inhibit COX in presence of peroxide which is synthesized at inflammation site. This peroxide is absent in brain, so it is more active on COX in brain (it has no effect on blood clotting mechanism).
- *Use*—headache, musculoskeletal pain, dysmenorrhea. It is first drug of choice for osteoarthritis and is also used in patient in whom Aspirin is contraindicated.
- *Pharmacokinetic*—it is well absorbed orally.
- *Plasma half life*—2 hours
- *Dose*—0.5-1 gm 6 hourly or TDS
- *Adverse effect*—it has safer action. On prolonged use liver damage can occur. Acute Paracetamol poisoning: Early manifestations are: nausea, vomiting, abdominal pain. After 12-18 hours, centrilobular hepatic necrosis and renal tubular necrosis, hyperglycemia and then coma. Treatment: Induce vomiting or gastric lavage. Activated charcoal to prevent further absorption.
- *Trade name*—T. Crocin 0.5, 1 gm, febrinil 300 mg/2 ml inj. T. Calpol 1 gm.

Patient Instruction for Use of Non-steroidal Anti-inflammatory Agents

- Take with a full glass of water.

- Take with food to minimize gastrointestinal irritation.
- Use caution with driving because of possible drowsiness or dizziness.
- If pain does not subside within a few days, call the dentist.

Opioid Analgesics

The dark brown, resinous material obtained from poppy capsule is called '*opium*'. These are plant products containing pharmacologically active ingredient i.e. alkaloid. It contains two types of alkaloids, viz. phenanthrene derivatives and benzoisoquinoline derivatives. They are also called *narcotic* drugs. The term narcotic is derived from the Greek word meaning '*stupor*' and was used for agents that produce sleep. The opioids bind to receptors located in the central nervous system, producing an altered perception of and response to pain.

Pharmacological Actions

- *Analgesia*—these drugs relieve severe pain like that of visceral pain and pain of trauma. Mechanisms by which they act are as follows:
 - They increase the threshold for painful stimuli. They act directly on the receptor site in the CNS to inhibit release of excitatory transmitters from primary afferents carrying pain impulses and elevate the pain perception threshold.
 - They alter emotional reaction to pain. They produce sleep which also elevates the pain threshold.
- *CNS*—these drugs have a site specific depressant and stimulant action in the CNS. It produces euphoria in the presence of pain. However, in absence of pain, it produces dysphoria; and, with an increased dose it produces sleep.
- *Respiration*—respiratory depression by reducing the sensitivity of medullary respiratory center neuron to CO_2 ; rate and tidal volume are both decreased.
- *Pupil*—miosis resulting in pin-point pupils.
- *CTZ*—nausea and vomiting can occur resulting from stimulation of the CTZ (chemoreceptor trigger zone) especially when the stomach is full.
- *Cough*—suppress cough by depressing the cough center.
- *Neuroendocrine*—the sex hormone and corticosteroid levels are lowered in the short term, but tolerance develops in the long term. Morphine can release ADH and reduce urine volume.
- *GIT*—these drugs increase tone and segmentation but decrease peristaltic propulsive movements. This produces spasm of intestine and sphincters. Secretion of HCl and intestinal secretions are decreased. These drugs increase absorption of H_2O , so lead to constipation.
- *Biliary tract*—there may be increase in intrabiliary pressure and may cause biliary colic.
- *CVS*—they cause vasodilatation by decreasing tone of blood vessels, histamine release and depression of vasomotor center. Hypotension may occur at toxic doses. Opioids are effective in relieving dyspnea of left ventricular failure because of reduced venous tone and decreased peripheral resistance.

Pharmacokinetics

- *Absorption*—Most opioid analgesics are absorbed well when taken orally. Absorption occurs from the lungs and from the nasal and oral mucosa whereas through GIT is slow and incomplete. A quick effect occurs following a subcutaneous injection.
- *Distribution*—they are partially bound to plasma proteins. The opioids can affect fetus in pregnant women.
- *Metabolism*—they are metabolized by conjugation with glucuronic acid in the liver.
- *Excretion*—they are excreted by glomerular filtration in the urine within 24 hours.

Adverse Effects

- *Constipation*—the opioids produce constipation by producing tonic contractions of the gastrointestinal tract.
- *Respiratory depression*—the opioid analgesic agonists depress the respiratory center in a dose-related manner. The depression is related to decrease in sensitivity of the brainstem to carbon dioxide.
- *Nausea and vomiting*—opioids often produce nausea and vomiting which is due to their direct stimulation of the chemoreceptor trigger zone (CTZ), located in the medulla.
- *Miosis*—the opioid analgesics cause miosis, an important sign (pinpoint pupils) in the diagnosis of an opioid overdose or an identical in addicts.
- *Urinary retention*—it increases smooth muscle tone in the urinary tract, thereby causing urinary retention.
- *CNS effects*—it may produce CNS stimulation exhibited by anxiety, restlessness, or nervousness.
- *Cardiovascular effects*—it may depress vasomotor center and stimulate the vagus nerve. With high dose, postural hypotension, bradycardia, and even syncope may result.
- *Biliary tract constriction*—in high doses, the opioids may constrict the biliary duct, resulting in biliary colic.
- *Apnea*—it may occur in newborns, when these drugs are given to mothers during labor pain.
- *Addiction*—it is proportional to their analgesic strength. As the use of opioids in dentistry is usually very less, this does not produce problems for dentist.
- *Allergic reaction*—it includes skin rashes and urticaria.

Summary chart						
Drug	Trade name	Dosage form	Dose	Indication	Contra-indication	Side effect
Salicylates (Aspirin)	Disprin Anacin Colsprin Biospirin	Tablet Injection	Analgesic / antipyretic— 0.3-0.6 gm TDS	Dental pain Headache Fever Arthritis Osteoarthritis Postmyocardial infarction	Hemophilia Hypersensitivity Peptic ulcer Gout Asthma Patient on anticoagulants	Nausea Vomiting GI disturbance Tinnitus Vertigo
Para-amino phenol derivative (Paracetamol)	Calpol Crocin Metacin Pacimol Febrinil	Tablet Injection Syrup Drops	0.5-1 gm TDS infant—50 mg 1-3 year— 60-80 mg 4-8 year— 240—320 mg 9-12 year— 300-600 mg	Pain Fever	No absolute contraindication Special precaution in hepatic and renal failure	Nausea Rash Leucopenia
Indole derivatives (Indomethacin)	Indocap Indoflam	Capsule Tablet Injection	25-50 mg 2 to 4 times a day neonates— 0.2 mg/ kg	Dental pain Rheumatoid arthritis Osteoarthritis Ankylosing spondylitis	Hypersensitivity Epilepsy Kidney disease Pregnancy Psychiatric cases	Gastric irritation Nausea Anorexia Diarrhea Asthma
Propionic acid derivatives (Ibuprofen Naproxen Ketoprofen)	Brufen Enflam Febrilix Combiflam Duoflam Nalyxan (Naproxen) Ostofen (Ketoprofen)	Tablet Capsule	Ibuprofen— 200-600 mg TDS Naproxen— 250 mg BD Ketoprofen— 50 mg BD	Postextraction pain Soft tissue injuries Rheumatoid arthritis Musculoskeletal disorders	Pregnancy Peptic ulcer Gastrointestinal bleeding Laceration	Gastrointestinal disorder Rash Hypersensitivity
Oxicam Piroxam	Pirox Dolonex Movon	Capsule Tablet Injection Gel	20-40 mg in divided or single doses	Post operative pain Osteoarthritis Rheumatoid arthritis	Hypersensitivity Pregnancy Lactation Children below 6 years Bronchial asthma	Heart burn Nausea Anorexia Rashes Pruritis Edema
Nimesulide	Nise Nulide Emsulide Nimsaid Nimulid Nimol	Tablet	Adult—100mg BD Children— 5 mg/kg /day in 2-3 divided doses	Dental pain Arthritis Gout Painful conditions Musculoskeletal pain	Peptic ulcer Hypersensitivity Hepatic impairment Pregnancy	Epigastric distress pain Nausea Rashes Edema
Aryl acetic acid derivatives Diclofenac sodium	Diclofen Diclomol Relaxyl Voveran	Tablet Gel	100-150 mg daily in 2-3 divided doses	Dental pain Arthritis Gout Painful post-operative condition	Peptic ulcer Hypersensitivity Pregnancy Lactation Asthma	Epigastric pain Nausea Rashes Edema Itching
Anthranilic acid Mephennamic acid	Mefac Meftal forte Spasmodol forte	Tablet Capsule Suspension	250-500 mg TDS	Pain Arthritis Osteoarthritis Dysmenorrhea As antipyretic	Hypersensitivity Epilepsy	Epigastric distress Rashes Hemolytic anemia Diarrhea
Ketorolac	Ketorol Ketanov Torolac	Tablet Injection	20 mg initially followed by 10 mg 4-6 hourly 30-60 mg IM followed by 10-30 mg 4-6 hourly	Short term management of postoperative pain Musculoskeletal pain	Hypersensitivity Syndrome of nasal polyps Peptic ulcer Coagulation disorders Angioedema	Gastric ulceration Bleeding Pain edema Headache Sweating

Drugs used in combination				
Drug	Dosage	Action and use	Adverse effect	Contraindication
Paracetamol + Ibuprofen	Adult— oral 325-500 mg Paracetamol + 100 mg Ibuprofen Children 125 mg Paracetamol + 100 mg Ibuprofen. TDS	It is a potent anti-inflammatory with analgesic and antipyretic action. Chronic pain, inflammatory dental conditions	Nausea, vomiting GIT and vision disturbances, rash	Active peptic ulcer, recent GI bleeding
Acetofenac + paracetamol	100 mg + 500 mg	It inhibits the synthesis of PGE ₂ and stimulates the synthesis of GAG. Chronic pain, inflammation	Nausea, vomiting, headache, vertigo, tinnitus	Hypersensitivity, pregnancy, peptic ulcer

- *Miscellaneous*—idiosyncrasy, allergy, tremor, delirium, sedation, mental clouding and lethargy.

Precaution and Contraindications

- *Infant and elderly persons*—they are more susceptible to respiratory depression.
- *Head injury*—as opioids depress the respiratory center, reduced ventilation produces vasodilation, and an increase in intracranial pressure.
- *Respiratory insufficiency*—it is dangerous to give these drugs in respiratory insufficiency as sudden death can occur.
- *Bronchial asthma*—morphine can precipitate an attack by its histamine releasing action.
- *Hypotensive states and hypovolemia*—there may be a fall in blood pressure.

Therapeutic Uses

- *Analgesics*—they are indicated in severe pain of any type. They provide symptomatic relief without affecting the cause. Opioids are used in traumatic, visceral, ischemic, postoperative, burn and cancer pain.
- *Preanesthetic medication*—morphine and pethidine are commonly used as preanesthetic medication.
- *Balanced anesthesia and neurolept analgesia*—morphine, pethidine and fentanyl are important components of these techniques.
- *Relief of anxiety and apprehension*—especially used in myocardial infarction and internal bleeding.
- *Acute left ventricular failure*—morphine affords dramatic relief by reducing preload on the heart due to

vasodilatation and peripheral pooling of blood.

- *Cough*—codeine or its substitutes are widely used for suppressing dry, irritating cough.
- *Diarrhea*—the constipating action of codeine has been used to check diarrhea and to increase consistency of stools.

Uses in Dentistry

- *Postoperative pain*—main use of narcotic analgesics in dentistry is for severe postoperative pain unresponsive to the anti-inflammatory analgesics.

Introduction

Fungi are eukaryotes and lack chlorophyll pigment. It possesses differentiated nuclei surrounded by nuclear membrane and reproduce either by budding or forming spores. It has rigid chitinous cell wall. Morphologically it may be either oval cells or long tubular septate hyphae showing true lateral branching. Fungi can be mould type, yeast type, yeast-like fungi (*Candida albicans*) and dimorphic fungi (Fig. 42-1).

Antifungal drugs are used in the treatment of superficial (Affecting oral mucous membrane, skin, nails, etc) and deep fungal infection (deeper tissues and organs). Fungal infections are caused by broad spectrum species of yeast like fungus including *Candida albicans*, *Cryptococcus neoformans*, *Histoplasma capsulatum*, *Blastomyces dermatitidis*, *Coccidioides immitis*, *Aspergillus fumigatus*, and many other pathogenic fungi.

Among these, *Candida albicans* has become most common organisms which is isolated from blood culture causes mainly oral fungal infection called as oral candidiasis or oral thrush. Oral candidiasis is most common fungal infection caused in humans and as variety of clinical

manifestations, it may be associated with the use of broad spectrum antibiotics, corticosteroids, cytotoxic drugs indwelling catheters, immunosuppressive therapy, dental implants, emergence of AIDS.

Types of Fungi

Fungi are either commensals or pathogenic. Pathogenic produces mycotoxins and enzymes causing harm.

- *Pathogenic fungi:*
 - Superficial
 - Deep
 - Truly pathogenic.

Classification

First Classification

Antibiotics

Polyenes

- Amphotericin B
 - Nystatin
 - Hamycin
 - Natamycin
- ##### Heterocyclic benzofuran

- Griseofulvin

Anti-metabolites

- Flucytosine

Azoles

Imidazole

Topical

- Clotrimazole
- Econazole
- Miconazole

Systemic

- Ketoconazole

Fig. 42-1: Different types of fungi.

Triazoles**Systemic**

- Fluconazole
- Itraconazole

Allylamine

- Terbinafine

Other topical agents

- Tolnaftate
- Undecylenic acid
- Benzoic acid
- Cyclopiroxolamine
- Quiniodochlor
- Sodium thiosulfate

Second Classification

According to its mode of action:

- Drugs that disrupt the fungal cell membrane-
 - Polyenes: Amphotericin B
 - Azoles: Imidazole, e.g. Ketoconazole, triazoles, Fluconazole
 - Allylamine: Terbinafine
- Drugs that inhibit mitosis: Griseofulvin
- Drugs that inhibit DNA synthesis: Flucytosine

Nystatin

It is polyene antibiotic obtained from *Streptomyces noursei*.

- **Trade name**—MYCOSTATIN
- **Preparation available**—Oral—5,00,000 unit tablets; Topical-100,000 unit/gm cream and ointments, 100,000 units vaginal tablets. It is available currently for topical use in creams, ointment, suppositories, lotion, suspension, vaginal tablets, and oral pastille.
- **Mechanism of action**—depending upon concentration used, it can be either fungistatic or fungicidal agent. Ergosterol is sterol found in cell membrane of fungi. It binds to the ergosterol and increases the permeability of cell membrane facilitating pore formation. These micropore formation allow leakage of intracellular ions and macromolecule leading to cell death.
- **Indication**
 - **Oral candidiasis (Oral thrush)**—Nystatin is drug of choice. it is commonly used as topical agent to suppress Candida infection. It is not administered parentally as it is toxic for systemic use. (1) Thrush is treated by holding 5 ml of nystatin suspension (for infants- 2 ml) in oral cavity for several minutes 4 times daily before swallowing. (2) Alternative treatment is to retain vaginal tablet in the mouth until it dissolves, at least 4 times a day. (3) Nystatin oral pastille (200,000 units) dissolved slowly in the mouth 5 times a day—can be mixed with glycerin. (4) Mycostatin creams and ointments (1 lack units) may be used in

candidiasis with angular cheilitis, stomatitis. (5) Mycostatin cream and ointments with absorbable corticosteroids and antibiotics may accelerate symptomatic effect. (6) Mycostatin oral rinse—1 teaspoon of nystatin oral suspension (100,000 unit/cc) mixed with ¼ cup of water is used as oral rinse for 3-4 times a day for 7-10 days.

- **Denture stomatitis (chronic atrophic candidiasis)**—0.2% chlorhexidine solution with Mycostatin tablet dissolves in it forming Gel are used mainly in such patients. In denture wearing patients, nystatin ointments is to be applied to the fitting surface of clean denture thoroughly and regularly and should be left out of mouth at night keeping it in hypochlorite solution.
- **Candidial angular cheilitis**—treatment with nystatin or Mycostatin yield good result.
- **Monilial diarrhea and monilial vaginitis**—nystatin is drug of choice. It is highly effective in monilial vaginitis in the dose of 1 tab 3-4 times a day (For children 1-2 million unit/day in divided doses in every 4-6 hours). For topical application, dissolves 1 tab in 5 ml of glycerin and then use.
- **Recurrent perianal/vaginal/vulvar and diaper candidiasis**—it is used topically.
- **Vulvovaginal candidiasis**—it is treated by application of vaginal tablet twice a day for 14 days, then nightly for an additional 14-21 days.
- **Mucocutaneous candidiasis**—topical Nystatin agent is applied on skin and mucosal surface 4 times a day gives better results.
- **Corneal infection / uterine infections**—cream, ointment, and vaginal tablets are commonly used. Nystatin is well tolerated in eye at the dose of 1,00,000 unit .1) Topical treatment: Eye drops containing nystatin 5-10 microgram. 2) Systemic treatment: nystatin tablets (250 mg) TDS for 2 weeks followed by 1 troche per day for three weeks.
- **Adverse effect**—fever, chills, headache, hypotension, rashes, nausea, and vomiting.
- **Contraindication**—Hypersensitivity reaction.

Amphotericin-B

Amphotericin B is an antifungal antibiotic produced by *Streptomyces nodosus*.

- **Trade name**—Fungizon, Abelcet, Ambisome, Amhotec.
- **Preparation available**—Parenteral: conventional formulation: Fungizone 50 mg power for injection. Lipid formulation: Abelcet—100 mg/20 ml suspension for injection. Ambisome—50 mg powder for inj. Amphotec—50,100 mg powder for inj. Topical: 3% cream, lotion, ointment.

- **Mechanism of action**—it binds to the ergosterol, the sterol of cell membrane of fungi increases the permeability of cell membrane facilitating pore formation. These pore formation allow loss of cation, intracellular ions and loss of calcium leading to cell death. It acts as fungicidal at high concentration and fungistatic at low concentration. It is effective against numerous fungi and yeast like *Candidia albicans*, *Cryptococcus neoformans*, *Histoplasma capsulatum*, *Blastomyces dermatitis*, *Coccidioides immitis*, *Rhodotorula*, *Aspergillus*, *sporothrix*.
- **Indication**
 - **Candidiasis**—amphotericin B remains the drug of choice for mainly oral, vaginal and cutaneous candidiasis. It is given in oral candidiasis (Oral thrush), acute atrophic candidiasis (antibiotic stomatitis), denture sour mouth (chronic atrophic candidiasis), chronic hyperplastic candidiasis (candidial leukoplakia). 1) Amphotericin B is mostly applied topically in the form of ointment, suspension, drops, cream, and lotion. It is applied 2-3 times a day. 2) In oral candidiasis- *Mystelcin elixir* containing both tetracycline and amphotericin used topically may prove to be beneficial. 1 ml suspension (100 mg/20 ml) is vigorously swished in the mouth and then swallowed, 4-5 times for 2-1 weeks. 3) In denture wearing patient, amphotericin B ointment applied to fitting surface of denture before it use. In candidial keratitis / corneal ulcers (conjunctivitis)- It is mostly applied topically by eyedrops containing 2.5 to 10 mg/ml. It cures only superficial infection because of its poor penetration. Subconjunctival injections are quite painful. Amphotericin B contains deoxycholate sodium which is highly toxic and irritating to eyes. Large doses may cause tissue necrosis.
 - **Mucosal leishmaniasis**. It is treated with intravenous Amphotericin B 0.1 to 1 mg/kg on alternate day with total dose of 1.5-2 gm.
 - **Fungal meningitis/cryptococcal meningitis**—intrathecal therapy with Amphotericin B is highly successful.
 - **Systemic fungal disease**—250 mg/kg daily, gradually increased if tolerated to 1 mg/kg by slow intravenous infusion over 4-6 hrs. Max. 1.5 mg/kg daily or on alternate day to a total dose of 3-4 gm is given over 2-3 months.
 - **Intestinal moniliasis/aspergillosis**—It is effective on topical use. It can be administered systemically in the dose of 50-100 mg in tablet form.
 - **Paronyllosis and intertriginous candidiasis**—apply 2-4 times daily to the affected area.
 - **Coccidioidomycosis**—it is given in Coccidioidal granuloma, valley fever, desert fever. Long term systemic therapy is required for complete cure.
- **Chromomycosis, chromo-blastomycosis, Phaeohyphomycosis**—Amphotericin B, intravenously or intralesional yield good treatment result.
- **Cryptococcosis (torulosis, European blastomycosis)**—intraoral lesions present over hard palate, extraction socket, tongue are mainly treated by oral application/topical use of Amphotericin B cream, ointment, 4-5 times daily for at least 14 days.
- **Histoplasmosis**—treatment includes systemic and topical use of Amphotericin B is the drug of choice. It gives good result. Long-term therapy may require.
- **Mucormycosis/Sporotrichosis/blastomycosis**—amphotericin B can use as an alternative drugs.
- **Adverse effect**—it is toxic drug causes impairment of renal and hepatocellular function, anemia, mental and neurological changes, renal toxicity.
Chills, fever, vomiting, headache, thrombophlebitis may occur if injected IV.

Hamycin

It is polyene antibiotics obtained from *Streptomyces pimprina*.

- **Trade name**—HAMYCIN
- **Preparation available**—Topical -4 lac unit/gm ointment, 5 lac unit vaginal ovules. 2 lac/ml suspension.
- **Mechanism of action**—same as Nystatin.
- **Indication**—oral thrush (due to *Candida albicans*)—ointment or suspension is applied to the affected area of oral mucosa with sterile cotton 2-3 times a day for 7-10 days. It can also be given in cutaneous candidiasis, monilial or *Trichomonas vaginitis*, histoplasmosis, pulmonary mycosis and otomycosis caused by *Aspergillus*. Dose recommended is 10-20 mg/kg daily.
- **Adverse effect**—mild rashes, irritation.
- **Contraindication**—Hypersensitivity.

Natamycin

This is a polyene antibiotic topically effective antifungal agent.

- **Trade name**—NATAMYCIN, PIMAFUCIN
- **Preparation available**—Topical- 5% suspension, 2% cream, 1% ointment and 25 mg vaginal Tabs.
- **Mechanism of action**- same as Nystatin.
- **Indication**—
 - Oral thrush/ Oral candidiasis: Natamycin vaginal tab or ointment is applied on affected area of oral mucosa for several minutes 3-4 times daily.
 - It can be given in vaginal candidiasis (25 mg vaginal tab is used topically).
 - *Trichomonas vaginitis* (used only topically).

- Ocular keratitis caused by fusarium, cephalosporium and other fungi. 5% Natamycin ophthalmic suspension as eyedrop is used topically 3-4 times a day.
- *Adverse effect*—nausea, mild rashes occasionally.

Griseofulvin

It is extracted from penicillium Griseofulvin. Griseofulvin was the first orally effective antifungal agent. It is effective against dermatophytes including Epidermophyton, Trichophyton, microsporum, etc. It is ineffective against Candida and *P. orbiculare*.

- *Trade name*—Dermofulvin, Grisactin, Grifulvin.
- *Preparation available*—Oral microsize: 125, 250 mg capsules, 250, 500 mg tablets, 125 mg/5 ml suspension. Oral ultramicrosize: 125, 165, 250, 330 mg tab.
- *Mechanism of action*—Griseofulvin binds to keratin in new forming skin cells and protects the skin from new infection. So, its action is to prevent infection of this new skin structure. It does not kill fungus which are already present.
- *Indication*—
 - *Dermatophytic infections*—Griseofulvin is effective against all superficial ringworm infection (skin and hair infection). It must be applied for 2-6 weeks on affected skin and hair to allow replacement of infected keratin.
 - *Fungal infection of nails and scalp*—Long therapy of griseofulvin may require to allow regrowth of new protected nails. For adult, 500 mg daily in single or divided doses with meal; For children, 10 mg/kg of body wt daily in single or divided dose with meals. Oral suspension is also available. Fingernails may respond to 6 month of therapy whereas toe nails may require 8-18 months.
 - *Fungal infection of tinea of hand, athlete's foot, tinea pedis, tinea manus*—it may require long therapy 500 mg daily in single/divided dose with meals for 3-4 weeks.
- *Adverse effect*—mild rashes, nausea, vomiting and headache, gastrointestinal upset, photophobia, peripheral neuritis.
- *Contraindication*—porphyria, liver disease, systemic lupus erythematosus.

Flucytosin

It is oral antifungal agent effective against systemic infection due to yeast and fungi. Its spectrum of action is much narrower than that of Amphotericin B.

- *Trade name*—ANCOBON
- *Preparation available*—Oral: 250, 500 mg capsule. 100-150 mg/kg/day in patient with normal renal function.

- *Mechanism of action*—it has antifungal action. Susceptible fungal cell take up flucytosin, convert it to fluorouracil, which is converted to 5-fluorodeoxyuridylic acid which inhibit DNA and RNA synthesis. But human cells are unable to convert parent drug to its active metabolites, so it is relatively non-toxic. It is widely distributed in the tissue including blood and CSF.
- *Indication*—it is mainly used as an adjuvant drug. *Cryptococcal meningitis*—It is used in amphotericin B to reduce its toxicity in dose of 100 mg/kg/day in 4 divided doses by an oral route. Systemic candidiasis with uterine/GIT infections. Aspergillosis and chromoblastomycosis: Flucytosin is used in combination with itraconazole.
- *Adverse effect*—prolonged use with high doses cause leukopenia, thrombocytopenia, and anemia due to bone marrow depression, nausea, vomiting, and skin rashes.

Clotrimazole

It is used exclusively as topical agent. It is toxic on parental administration.

- *Trade name*—Mycoban, Lotrimin Mycelex, Surfaz.
- *Preparation available*—Topical: Mycoban Gel 12% (30 gm), Gynostatum vaginal tab, 1% vaginal cream, lotion, solution. Oral: 100 mg, 200 mg, 500 mg tab.
- *Mechanism of action*—it inhibits the synthesis of ergosterol by binding to catalytic haem ion of fungal cytochrome resulting in damage to cell membrane of fungi.
- *Indication*—
 - Candidiasis caused by *Candida albicans*, oral candidiasis, cutaneous candidiasis.
 - Treatment of tinea pedis (athlete's foot), tinea cruris (jock itch), tinea corporis (ringworm).
 - Vaginal infection—1 vaginal tab 100mg intra-vaginally at bed time for 7 consecutive days. Then in alternative days 1 tab (200 mg) intravaginally at bedtime for 3 consecutive days.
 - *Dermatophytic infections like candidiasis and seborrheic dermatitis*—Topical antifungal-corticosteroid fixed combination has been recently introduced. Clotrimazole-betamethasone dipropionate cream (lotrisone) is used once or twice daily, applied to the affected area results in the clearing of superficial dermatophytic infection in 2-3 weeks.
 - *Skin infection caused by corynebacteria*—it is well tolerated by topical use.
 - *Oropharyngeal candidiasis* : it is used in the dose of 10 mg daily (TDS)
 - *Pityriasis versicolor*—100 to 500 mg/daily is quite effective.

- Toxoplasmosis, Aspergillus infection of eye—1% suspension is to be applied topically hourly, then 4 times a day for 8-12 weeks. In case of intraocular infection, both topical and oral dosage of 60 mg/kg/day for 1-2 weeks to achieve normal intraocular level, then discontinue.
- *Adverse reaction*—local burning or stinging, skin irritation, rash, hypersensitivity.
- *Contraindication*—1st trimester of pregnancy.

Econazole

It is antifungal agent mainly used topically.

- *Trade name*—ECANOL, SPECTAZOLE.
- *Preparation available*—Topical: 1% cream-10 gm.
- *Mechanism of action*—same as Cotrimazole.
- *Indication*—
Treatment for trichomoniasis—1% ointment, 150 mg vaginal tablets is applied to affected area of skin or oral mucosa twice a day for 7-10 days. Mucocutaneous candidiasis—it is used as an oral rinse, cream, ointment as well as suspension. Vaginal tab dissolved in ¼ cup of water and used as oral rinse for oral candidiasis. Dermatophytosis—mostly applied topically 2-3 times a day. Pityriasis versicolor.
- *Adverse effect*—local burning or stinging, skin irritation, rash.

Miconazole

It is used mostly as topical antifungal agent. It is more toxic than ketoconazole.

- *Trade name*—MICOGEL, MONISTAT, MICATIN.
- *Preparation available*—Topical: ointment 2%-15 gm, lotion 2%-15 ml, powder 2%-15 gm, cream 2%-15 gm, gel 2%-15 gm, vaginal suppositories- 100, 200 mg.
- *Mechanism of action*—same as Cotrimazole.
- *Indication*—
 - *Severe systemic fungal infection*—in adult, 1200 to 2400 mg/day in divided doses.
 - *Cutaneous candidiasis*—applied cream, ointment to affected area twice daily for 7 days.
 - *Systemic mycosis*—Miconazole is used by intravenous route (Monistat).
 - *Ocular infection*—Topical (1%) for every hours and subconjunctival injection of 5 mg miconazole (1%) MICOPTIC OPICOPS once/twice a day.
 - *Other*—chronic mucocutaneous candidiasis, fungal meningitis, fungal urinary tract infection. vulvo-vaginal candidiasis, Tinea pityriasis versicolor, otomycosis.
- *Adverse effects*—Chills, fever, itching, nausea, rashes, phlebitis, anemia, irritation to skin.

Ketoconazole

It was first orally effective azole antifungal agent used in the treatment of systemic fungal infection. It is less toxic than Amphotericin B.

- *Trade name*—Nizoral, Tocon, Fungicide, Funazole.
- *Preparation available*—Oral: Tab 200 mg, Topical: 2% cream, and shampoo.
- *Mechanism of action*—same as Cotrimazole.
- *Indication*—
 - *Mucocutaneous candidiasis*—Tab 200 mg once a day is very effective.
 - *Paracoccidioides mycosis and Chromoblastomycosis*—for adults, 200-400 mg once daily preferably after food; for children after 2 years, 3.3 to 6.6 mg/kg once daily.
 - *Histoplasmosis*—because of toxicity of amphotericin B, ketoconazole is mostly preferred in histoplasmosis.
 - *Leishmaniasis*—oral ketoconazole 600 mg/day for 28 days is most effective in cutaneous Leishmaniasis.
 - *South America blastomycosis / Almeida's disease*—Ketoconazole has been successfully tried in the recent year.
 - *Dermatophytosis, candidiasis, seborrheic dermatitis*—1) Oral dose of 200 mg daily for 2-3 weeks, can be given. 2) Ketoconazole (Nizoral) available as a cream for topical treatment. 3) Shampoo 1% is used for seborrheic dermatitis (Nizoral AD Shampoo).
 - *Ocular infection*—ketoconazole 200 mg tab containing ointment are used.
- *Adverse effect*—nausea, vomiting, loss of appetite, giddiness, headache, rashes, photophobia, paresthesia. It interferes with biosynthesis of adrenal and gonadal steroid hormone producing gynaecomastia, infertility, menstrual irregularities and GIT upset.

Fluconazole

It is new antifungal drug which is more water soluble and has good penetration into cerebrospinal fluid, ocular fluid, vaginal tissue and saliva. It can be administered intravenously or orally.

- *Trade name*—SYSCAN, DIFLUCAN.
- *Preparation*—Oral 50, 100, 150, 200 mg tablets, Topical: powder for 10, 40 mg/ml suspension. Parenteral-2 mg/ml in 100 and 200 ml vial.
- *Mechanism of action*—it acts by inhibiting the enzyme demethylase resulting in the damage to fungus cell membrane. It has fungistatic action.
- *Indication*—
 - *Cryptococcal meningitis*—Fluconazole is drug of choice for treatment and secondary prophylaxis of cryptococcal meningitis. Drug available in oral/

intravenous formulation at the dosage of 100-800 mg/day. For fungal prophylaxis: 50-100 mg once a day.

- *Mucosal candidiasis/mucocutaneous candidiasis*—Ketoconazole can be given orally in the dose of 50-100 mg daily for 14-30 days or intravenously. For mucosal infection, topical application may be useful.
- Systemic candidiasis—for systemic infection, 400 mg of ketoconazole either orally or intravenously on first day then 200-400 mg once a day for 15-30 days. For children: 3-6 mg/kg BW daily in severe life threatening infection in over 1 year.
- Coccidioid disease.
- Prophylactic agent for bone marrow transplantation recipients and AIDS patient. Prophylactic use of fluconazole to reduce fungal infection are used
- *Dermatophytic infection*—alternate day doses of 100-200mg are sufficient to treat them.
- *Sporotrichosis, histoplasmosis, vaginal candidiasis*—200 mg on first day followed by 100 mg daily once a day are quite effective to reduce fungal infection.
- *Adverse effect*—nausea, headache, abdominal pain.

Itraconazole

It is newer antifungal drug which is administered orally. Its efficiency is enhanced in combination with flucytosine.

- *Trade name*—ITROLE, CANDITRAL, SPORANOX.
- *Preparation available*—Oral: 100 mg, 200 mg Capsule. Topical: 10 mg/ml solution. Parenteral: 10 mg/ml for IV infusion.
- *Mechanism of action*—same as Fluconazole.
- *Indication*
 - *Oropharyngeal candidiasis*—oral liquids and intravenous preparation are quite effective in the dose of 200 mg capsule/tablets twice daily for at least 6 month, yields good results.
 - Dermatophytoses treatment
 - *Onychomycosis*—dose of 200 mg daily taken with the food to ensure maximum absorption for 3 consecutive months.
 - *Other*—Aspergillosis, histoplasmosis, sporotrichosis and blastomycosis.
- *Adverse effect*—peripheral neuropathy, headache, dizziness, allergic reaction, jaundice, hepatotoxicity.

Terbinafine

It is new systemic antifungal agent. It has higher efficiency comparable to itraconazole with decreased risk of hepatotoxicity.

- *Trade name*—LAMISIL.
- *Preparation available*—Topical: 1% cream. Oral: 10 mg (tab 250 mg/ day orally).

- *Mechanism of the action*—Terbinafine mainly act as fungicidal. It binds with ergosterol in the cell membrane of fungi, increases the permeability of cell membrane and allows the leakage of macromolecules and anions from cell results in fungal cell death.
- *Indication*—
 - Onychomycosis of the fingernails (Oral preparation in the dose of 250 mg once a day for 6 weeks), onychomycosis of toe nails (oral preparation—250 mg once a day for 12 weeks. 1% cream is used for local application once or twice a day).
 - Dermatophytic infection (topical application of 1% cream for 1 week, but should not exceed 4 weeks).
- *Adverse effect*—local irritation, stinging, dryness.

Newer Antifungal Drugs

- *Silver sulfadiazine (SSZ)*—SSZ has broad spectrum of antifungal activity against Candida, Aspergillus, Fusarium, other fungal infections of the eye.
 - *Trade name*—APLICAPS.
 - *Preparation*—Topical: 1% suspension, Oral: 250 mg tablets.
 - *Indication*—it is used in fungal infection of the eye caused by Candida, Aspergillus, and Fusarium. 1% suspension is used, 5 times a day. SSZ is also available in 1% eyedrops and ointment 1%—applied topically 4-5 times daily.
- *Tolnaftate*—it is newer antifungal drug used topically in the form of creams, powder. It is active against only growing cells. It is resistant to Candida, i.e. *Candida albicans*.
 - *Preparation*—Topical: solution, cream, gel, aerosol powder.
 - *Indication*—it is used in dermatomycophytosis—Topically Gel, Solution or aerosol powder mixed with glycerol is applied over affected area of skin twice a day). It is also used in tinea cruris and tinea corporis. Topical application may be useful.
 - *Adverse effect*—allergic reaction, irritation.
- *Naftifine*—it is newer antifungal drug highly active against dermatophytes.
 - *Preparation*—it is available in 1% cream, gel. Contact with mucous membrane should be avoided.
 - *Indication*—Dermatomyophytosis—Topically applied over the skin is quite effective.
- *Cyclopirox olamine*—it is newer antifungal agent with high cure rates. It has good penetration power.
 - *Trade name*—LAPROX.
 - *Preparation*—1% cream, lotion.
 - *Indication*—it is used in Tinea infections, Dermatophytosis, Candidiasis—Topical application of cream or lotion over skin and oral mucosa, 4-5 times

a day yield good results due to good penetration power.

- *Benzoic acid*—Application of this must be continued till infected keratin is shed. It is used in hyperkeratotic lesion—“*Whitfield’s* ointment contains benzoic acid 5%, salicylic acid 3%. It is used in dermatological infection caused by fungus and bacteria.
- *Undecylenic acid*—it is newer fungistatic agent used in combination with zinc salts.
 - Trade name—CRUEX, DENSENEX.
 - Preparation—10-25% powder, cream, ointment.
 - Indication—It is used in tinea cruris, tinea pedis, skin rash and superficial mycoses.
- *Haloprogin*—it is newest drug having antifungal activity.
 - Trade name—HALOTEX.
 - Preparation—1% cream, solution.
 - Indication—Ringworm infection, Dermal candidiasis.
- *Voriconazole*—it is newest trizole to enter clinical trials. It is available in an intravenous and oral formulation. Recommended dosage is 400 mg/day. It has broad spectrum of action mainly against *Candida* species.

Voriconazole is most effective than itraconazole in candidial infection.

- *Indication*—Oral thrush: Orally or intravenously administered in the dose of 400 mg/day. *Mucocutaneous reparation*—Topical 10% ointment, cream.
- *Indication*—tinea corporis, superficial mycosis and hyperkeratinised lesion: used in combination with salicylic acid.
- *Sodium thiosulfate*—it is weak fungistatic agent useful in pityriasis versicolor. It is not effective in superficial mycosis.
 - Trade name—KARPIN
 - Preparation—2% lotion, solution.
 - candidiasis, dermatophytosis.
- *Butenafine*—it is newer antifungal agent used mostly in the treatment of superficial dermatophytosis.
 - Trade name—MENTAX.
 - Preparation—Topical 1% cream or lotion.
- *Buclosamide*—It is less effective than imidazole.
 - Trade name—JADIT.

Summary Chart

Drug	Trade name	Dosage form	Dose	Indication	Contraindication	Adverse effect
Amphotericin B	Fungizone	Tablet Injection	50-100 mg QID 0.3 mg /kg body weight 4-8 hourly as an infusion	Oral, vaginal cutaneous candidiasis, otomycosis, systemic mycosis, intestinal moniliasis, kala azar	Renal impairment, Epilepsy	Acute reaction, chills, fever, nausea, vomiting, long term nephrotoxicity
Nystatin	Mycostatin	Tablet	5-10 lac units 2-3 times daily	Moniliasis, kala azar, oral candidiasis, intestinal moniliasis	Hypersensitivity	Nausea, diarrhea and bad taste
Hamycin	Hamycin	Suspension	2 lac units /ml 2-3 times daily	Oral thrush	Hypersensitivity	Sensitization, irritation
Griseofulvin	Dermofulvin Fungal 500	Tablet	500-1000 mg daily IM	Fungal infection of skin, nail and scalp	Porphyria, severe liver disease, systemic lupus erythematosus	Headache, irritation
Ketoconazole	Nizral Tocon	Tablet	200 mg OD/BD	Systemic candidiasis, Dermatormycosis	Children below 2 yrs	Hepatitis, rashes, GIT upset
Terbinafin	Exifine Sebifin	Tablet	250 mg /day OD 2-6 weeks	Fungal infections of skin, nails and onychomycosis	Hypersensitivity, Liver dysfunction	GIT symptoms, skin rashes and reaction
Fluconazole	F-zole Fluzone	Capsule Tablet Infusion	200 mg on 1st day followed by 100 mg OD	Systemic vaginal and mucosal candidiasis	Hypersensitivity	Nausea, headache, skin rashes and abdominal pain
Itraconazole	Itrole Canditral	Capsule	100-200 mg OD for 6 months	Oropharyngeal candidiasis, Systemic mycosis, Chronic mucocutaneous endocrinopathy	Hypersensitivity	Nausea, headache, skin rashes and abdominal pain

Anticancer Drugs

5

Introduction

Anticancer drug is used in the treatment of malignant tumors. It selectively kills tumor cells by virtue of cell kinetic proliferation character and cell biology. It produces only temporary or partial tumor regression. It may be used in combination with radiotherapy or surgery or as palliative treatment where the treatment of cancer is not possible.

Factors Affecting Chemotherapy

- *Cells synthesizing DNA*—response to chemotherapy is proportional to the number of cells synthesizing DNA.
- *Doubling time*—the shorter the doubling time at the onset of treatment, the better is the response as more cells will synthesize DNA.
- *Size of tumor*—as tumor grows, it becomes difficult to cure.

Kinetic Classification of Anticancer Drugs

- *Phase dependent*—it kills cells exponentially at a lower dose but reaches the plateau (a state of little or no changes following a period of activity or progress) at a higher dose. As they can kill cells only during a specific part of the cell cycle they are also called as 'cell cycle specific drugs', e.g. G₁ (vinblastine), S (hydroxy urea), G (daunorubicin), and M (vinblastine).
- *Non-phase dependent*—it kills cells exponentially with an increasing dose and is especially toxic for both; cells in all stages of the cycle and those in G₀ phase, e.g. nitrogen mustard, cyclophosphamide, chlorambucil, dacarbazine.

Principles of Chemotherapy

The Cells Kill Hypothesis of Skipper

Skipper formulated some principles while studying tumor cells in mice suffering from leukemia which showed that:

- The survival of an animal was inversely related to the tumor burden.
- A single leukemic cell is capable of multiplying and killing the host.
- For most drugs, there is a clear relationship between dose of the drugs and eradication of tumor cells.
- A given dose of a drug kills a constant fraction of cells and not a constant number. The same amount of drug is required to reduce the burden from one million cells to 10 cells as from 1 lacks to 1 cell.
- Implication of this cell kill hypothesis is that tumors are best treated when they are small in volume and the treatment must continue until the last cell is eradicated.
- If the treatment is discontinued as soon as the tumor is no longer clinically detectable, at least 10⁹ tumor cells will remain unkilld and relapse is inevitable.

The Norton Simon Hypothesis

- In the tumor, which show Gompertzian type of growth curves, the rate of regrowth increases as the tumor shrinks with the therapy.
- Thus, the level of treatment adequate to initiate a regression may be insufficient to maintain the regression and produce cure. So to overcome this, Norton and Simon hypothesized that to counteract the slowing rate of regression in a tumor responding to therapy, it is necessary to increase the intensity of treatment as the tumor becomes smaller.
- Some time radiotherapy and marrow transplantation can be used to intensify the treatment.

- Multidrug regimens are used to attack residual population of cells, biochemically resistant to the initial combination of drugs.

The Goldie Goldman Model

In 1979 Goldie and Goldman produced a model to explain the development of resistance to anticancer drug by the tumor cells and suggested that the population of cells within the tumor were capable of randomly becoming resistant to the cytotoxic agents by means of spontaneous mutation.

Use of Anticancer Drugs

- *Cure of prolonged remission*—this is now possible in acute leukemia, Wilm's tumor, Ewing sarcoma, retinoblastoma, rhabdomyosarcoma, choriocarcinoma, lymphosarcoma, Burkitt's lymphoma and testicular teratomas.
- *Palliative treatment*—it gratify results by shrinkage of tumors, alleviation of symptoms. Life is prolonged in breast cancer, prostatic carcinoma, and small cell cancer of lung, chronic lymphatic leukemia, chronic myeloid leukemia and non-Hodgkin's lymphoma.
- *Adjuvant chemotherapy*—these are used to mop up any residual malignant cells after surgery or radiotherapy.
- *Combination chemotherapy*—anticancer drugs can be used in combination. The drug should be active against the tumor when use alone, should have different mechanism of action and have minimally overlapping toxicity. By using several drugs which attack the cells in different ways it is hoped that the development of resistant cells will be inhibited.

Classification

Alkylating Agents

- Alkyl Sulfonate—Busulfan
- Nitrogen Mustards—Mustine HCl, Cyclophosphamide, Melphalan and Chlorambucil
- Nitrosoureas—Carmustine (BCNU), Lomustine (CCNU), Semustine (Methyl-CCNU)
- Triazine—Dacarbazine
- Ethylenimine—Thio- TEPA

Anti-Metabolites

- Purine antagonist—6-Mercaptopurine, 6-Thioguanine
- Folate antagonist—Methotrexate
- Pyrimidine antagonist—5-Fluorouracil, Cytarabine (cytosine arabinoside).

Antibiotics

- Actinomycin-D

- Mitoxantrone
- Bleomycin
- Daunorubicin
- Doxorubicin
- Mithramycin
- Mitomycin C

Vinca alkaloids

- Vinblastine
- Vincristine

Taxanes

- Paclitaxel
- Docetaxel

Epipodophyllotoxin

- Etoposide
- Teniposide

Enzymes

- L-Asparaginase

Miscellaneous

- Hydroxyurea
- Procarbazine
- Cisplatin
- Hexamethylamine
- Carboplatin

Alkylating Agents

They produce their effect by linking an alkyl group ($R-CH_2$) covalently in protein and nucleic acid. Some of them are described below:

Alkyl Sulfonate

- *Busulfan*—It is highly specific for myeloid elements, granulocyte precursors being most sensitive, followed by those of platelets and RBCs.
- *Use*—It is the drug of choice of chronic myeloid leukemia.
- *Dose*—2-6 mg/day orally.

Nitrogen Mustards

- *Mechanism*—it has two chloroethyl side chains. One of them forms a cyclical highly reactive ammonium ion which binds to nucleic acids, i.e. 7-nitrogen group of guanine. The other chloroethyl sides of nitrogen mustards can crosslink with DNA strands, either within a strand or between strands. Although alkylating agents may bind to variety of cellular components like cytoplasmic proteins and RNA at therapeutic doses, impairment of DNA replication is the major mechanism of cytotoxicity of these drugs. Damage to DNA is more serious during the 'S' phase of cell cycle probably

because the cell has less time to excise the damage to DNA fragment.

- *Mustine HCl*—It is the first nitrogen mustard, highly reactive and local vesicant. Dose—0.4 mg/kg IV in 1-4 days.
- *Cyclophosphamide*—it has prominent immunosuppressant property. Dose—2-3 mg/kg/day orally, 10-15 mg/kg IV every 7-10 days.
- *Chlorambucil*—it is the slow acting alkylating agent, especially active on lymphoid tissue. It is drug of choice for chronic lymphatic leukemia. Dose—4-10 mg daily for 3-6 weeks, then 2 mg daily for maintenance.
- *Melphalan*—it is very effective in multiple myeloma. Dose—10 mg daily for 7 days or 6 mg/day for 2-3 weeks and after 4 weeks' gap, 2-4 mg daily for maintenance orally.

Nitrosoureas

- *Mechanism*—they act partly as alkylating agents linking to an alkyl group or carbonyl group of cell proteins and form compounds which are unstable in water and decompose to form alkylating groups, which are able to damage the cell proteins.
- *Dose*—BCNU—50-200 mg/m², CCNU 100-130 mg/m², methyl CCNU—100-200 mg/m².

Triazine

- *Dacarbazine*—it is different from other alkylating agents in having primary inhibitory action on RNA and protein synthesis. It is activated in the liver. It is used in malignant melanoma. Dose—3.5 mg/kg/day IV for 10 days, repeat after 4 weeks.

Ethylenimine

- *Thio-TEPA*—it does not require formation of an active intermediate. It has high toxicity and seldom used today. Dose—0.3-0.4 mg/kg IV at 1-4 weeks intervals.

Anti-metabolites

Purine Antagonist

- *Mechanism of action*—Mercaptopurine and thioguanine are highly effective anti-cancer drugs. It inhibits conversion of inosine monophosphate to adenine and guanine nucleotides.
- *Use*—they are useful in childhood acute leukemia and choriocarcinoma.
- *Toxic effect*—main toxic effects of antipurines are bone marrow depression which develops slowly.
- *Dose*—6-Mercaptopurine (2.5 mg/kg/day) and 6-Thioguanine (2 mg/kg/day).

Folate Acid Antagonist

- *Action*—Most commonly used folic acid antagonist is methotrexate. It inhibits the conversion of dihydrofolate to tetrahydrofolate which in turn is converted to a variety of coenzymes. It blocks thymidylate monophosphate synthesis and thus inhibiting RNA and DNA synthesis and so methotrexate is 'S' phase specific.
- *Absorption*—it is well absorbed from the gut at lower doses (up to 100 mg) but higher doses should be given intravenously. After IV injection, there is a rapid early half life of 45 minutes, a slower phase of renal excretion of about 3 hours and then a very long terminal half. Methotrexate does not penetrate the CSF at conventional doses. To ensure adequate levels in CSF, methotrexate may be given intrathecally at a dose of 10 mg/m².
- *Toxicity*—the prolonged clearance of methotrexate is responsible for the toxicity to marrow gut and mucous membrane which leads to bone marrow depression, diarrhea and oral ulceration. The toxicity of methotrexate can be reversed by folic acid.
- *Contraindications*—it should be avoided in patients with ascites or pleural effusion as the drug may accumulate in fluid reservoirs and will release slowly causing toxicity.
- *Indications*—Used in treatment of acute leukemia, non-Hodgkin's lymphoma, breast cancer and osteogenic sarcoma.
- *Dose*—in choriocarcinoma 15-30 mg/day for 5 days orally or 20-40 mg/m² IM or IV twice a week. In maintaining remission in children with acute leukemias, 2.5-15 mg/day is useful.

Pyrimidine Antagonists

- *Action*—most commonly used are 5-fluorouracil and cytarabine. It interferes with nucleic acid synthesis by antagonizing or mimicking pyrimidine metabolites.
- *Absorption*—it may be given orally but its absorption is unpredictable. So, the IV route is often used because the plasma clearance is rapid.
- *Toxicity*—nausea, vomiting, stomatitis, alopecia and myelosuppression.
- *Indications*—it is given in the treatment of breast and GIT cancer, Hodgkin's lymphoma, non-Hodgkin's lymphoma, acute leukemia to induce remission.
- *Dose*—fluorouracil—1 gm orally on alternate day for 6 days followed by 1 gm weekly or 12 mg/kg/day IV for 4 days. Cytarabine—1.5-3 mg/kg IV BD for 5-10 days.

Antibiotics

Practically all of the antibiotics intercalate between DNA strands and interfere with template function.

Actinomycin-D

- **Action**—it is isolated from streptomyces. It is intercalated between guanine and cytosine base pairs and blocks the transcription of DNA and DNA related RNA synthesis. It inhibits division of rapidly dividing cells. It is given intravenously and plasma clearance is within a few minutes.
- **Toxicity**—nausea, vomiting, mucositis, diarrhea and myelosuppression.
- **Indications**—it is active against rhabdomyosarcoma, Wilm's tumor Ewing's sarcoma, and teratoma.
- **Dose**—it may be given as a single injection of 15 µg/kg IV daily for 5 days or in combination with cyclophosphamide and vincristine.

Mitoxantrone

- **Action**—it binds to DNA and is given intravenously and has a long terminal half life of 36 hours.
- **Toxicity**—it may cause myelosuppression, cardiomyopathy and alopecia.
- **Indications**—acute non-hemolytic leukemia, chronic myelogenous leukemia, non-Hodgkin lymphoma and carcinoma of breast.
- **Dose**—12 mg/m² single IV dose repeat at 3 weeks.

Bleomycin

- **Action**—It consists of a mixture of closely related glycopeptide antibiotics. It inhibits DNA synthesis and causes a break in DNA and is active in G₂ phase of the cell cycle.
- **Absorption**—It is given by parenteral, subcutaneous or intramuscular route because it is non-vesicant. It has initial half life of 30 minutes and elimination from plasma takes 2-9 hours. It is excreted by kidney and does not cross the CSF.
- **Toxicity**—skin pigmentation, erythema, vesiculation or fibrosis.
- **Indications**—it is used in combination with other chemotherapeutic drugs in testicular carcinoma, head and neck cancer and Hodgkin's lymphoma.
- **Dose**—30 mg per injection twice weekly IV.

Doxorubicin and Daunorubicin

- **Action**—These are antitumor antibiotics and are produced by streptomyces fungus. They are capable of causing breaks in DNA strands by activating topoisomerase II and generating quinone type radicals.
- **Absorption**—they are given by IV route and cleared from plasma, metabolized in liver and excreted in bile. So great care should be taken while prescribing in liver dysfunction patients.

- **Toxicity**—nausea, vomiting, alopecia and diarrhea occur. Cardiotoxicity can occur which manifests as ECG changes, arrhythmias and hypotension.
- **Indications**—doxorubicin is given in lymphoma (Hodgkin's disease), small cell cancer, breast cancer and daunorubicin is given in acute myeloid and lymphatic leukemia. Daunorubicin used is limited to acute leukemia.
- **Dose**—doxorubicin—60-75 mg/m² IV every 3 weeks and daunorubicin—30-60 mg/m² IV daily for 3 days and repeat weekly.

Mithramycin

- **Action**—its use is restricted to embryonal testicular tumor, disseminated cancers, especially those with bony metastasis and hypercalcemia. It reduces serum calcium levels, probably by direct action on bone inhibiting calcium release.
- **Dose**—25 µg/kg by slow IV infusion daily or on alternate days.

Mitomycin-C

- **Action**—it is derived from streptomyces species and inhibits DNA synthesis by both cross linking and alkylating DNA.
- **Toxicity**—myelosuppression, cumulative thrombocytopenia and renal toxicity.
- **Indications**—used in combination in cancer of breast, stomach, cervix, pancreas and those of head and neck.
- **Dose**—10 mg/m² IV.

The Vinca Alkaloids

They are mitotic inhibitors, which bind to 'tubulin' (proteins of the cellular microtubules) to cause disruption of mitotic spindle and interfere with cytoskeletal function. The vinca alkaloid blocks assembly of A and B subunit of the tubulin preventing the formation of the microtubules.

Vinblastine

- **Absorption**—these drugs are given IV and are vesicants if extravasated. Plasma clearance occurs in 3 phases with half life of 4 minutes, 1 hour and 16 hours. Tissue binding is extensive and prolongs the actions and the drug binds to platelets, red cells and plasma proteins.
- **Indications**—it is used in combination for treatment of testicular tumors and lymphoma.
- **Toxicity**—it causes alopecia, neurotoxicity and myelosuppression.
- **Dose**—0.1-0.15 mg/kg IV weekly in 3 doses.

Vincristine

- *Use*—it is a rapidly acting drug, very useful for inducing remission in childhood acute leukemia.
- *Toxicity*—it causes peripheral neuropathy, alopecia.
- *Indications*—it is medicated in lymphoma (Hodgkin's disease), acute lymphatic leukemia, small cell cancer of bronchi and breast cancer.
- *Dose*—1.5 mg/m² IV weekly.

Taxanes**Paclitaxel**

- *Action*—it is a complex diterpin taxane from bark of the Western yew tree. It enhances polymerization of tubulin. The microtubules are stabilized and their depolymerization is prevented.
- *Indications*—it is used in metastatic ovarian and breast carcinoma after failure of first line chemotherapy and in relapse cases. It can be used in head and neck cancer, small cell lung cancer.
- *Dose*—175 mg/m² by IV infusion over 3 to 24 hours repeated every 3 weeks.

Docetaxel

It is a congener of paclitaxel with the same mechanism of action. It has been found to have efficacy in metastatic breast cancer refractory to first line drugs. Major toxicity is neutropenia.

Epipodophyllotoxin

- *Action*—these are phase specific and prevent cells from entering mitosis from G₂ phase.
- *Absorption*—the drugs are absorbed erratically from the gut with the plasma availability up to 50%, rapid clearance from plasma occurs when given intravenously followed by a slower phase.
- *Etoposide*—it is highly protein bound and is excreted in the urine in 72 hours.
- *Teniposide*—it is active as a single agent in small cell lung cancer.
- *Toxicity*—they cause alopecia, myelosuppression, mucositis and neuropathy.
- *Indications*—it is used in treatment of testicular tumors, leukemia and lymphoma.
- *Dose*—100 mg in 5 ml injection or 120 mg/m² IV infusion for 30 minutes.

Enzymes

- *L-Asparaginase*—this enzyme is produced by *E. coli*.
- *Action*—it acts by removing asparagine from the circulation, thus depressing those tumor cells which are

unable to synthesize asparagine due to lack of or have very low levels of asparagine synthetase.

- *Route of administration*—drug is usually given intravenously after a skin test for hypersensitivity.
- *Indications*—it is used in the remission period in acute lymphocytic leukemia.
- *Toxicity*—anaphylaxis, pancreatitis, hypoglycemia, hypoproteinemia, encephalopathy and nausea.
- *Dose*—50-200 KU/kg IV daily for 2-4 weeks.

Miscellaneous Agents**Hydroxyurea**

- *Action*—it blocks the conversion of ribonucleotides to deoxyribonucleotides by inhibiting the enzyme ribonucleoside diphosphate reductase interfering with DNA synthesis. It is 'S' phase specific. It is well absorbed orally and crosses the CSF.
- *Toxicity*—it causes neutropenia and gut disturbance. There is also myelosuppression.
- *Indications*—it is used in chronic granulocytic leukemia, polycythemia vera.
- *Dose*—20-30 mg/daily for 8 weeks.

Procarbazine

- *Action*—this is a weak mono-aminoacid oxidase inhibitor which inhibits action of DNA and RNA and depresses proline synthesis. It also causes chromosomal damage.
- *Absorption*—it is well absorbed from the gut and is one of the few drugs which penetrate the CSF.
- *Indications*—it is used mainly in Hodgkin's disease and brain tumor.
- *Toxicity*—it includes nausea, vomiting and leukopenia.
- *Dose*: 100 -300 mg orally daily for 2 weeks.

Cisplatin

- *Action*—this drug is the only active cytotoxic agent in its cis form. Chloride ions are lost from the molecule after it diffuses into the cell and the compound crosslinks mainly to guanine groups like an alkylating agent. It should be protected from light and is given intravenously with an early half life of about 40 minutes with a later slower phase of clearance i.e. about 60 hours.
- *Absorption*—about 90% of cisplatin bound to plasma protein is taken up in the kidney, gut, liver, testis and ovary, but it does not cross the blood-brain barrier. It is excreted by the kidney.
- *Toxicity*—it is nephrotoxic, ototoxic and may cause severe nausea and vomiting. Renal damage may be cumulative. Magnesium wasting may occur as a result of renal damage. If it is given in large doses it is associated with peripheral neuropathy, predominately affecting sensory nerve endings.

- **Indications**—it is very effective in testicular tumors and in ovarian cancer. It is also effective in bladder, head and neck tumors, small cell cancer of bronchi and osteosarcoma.
- **Dose**—50-100 mg/m² every 3-4 weeks.

Hexamethylamine

- **Indications**—it is active against ovarian and cervical cancer.
- **Absorption**—it is well absorbed from the gut.
- **Toxicity**—it causes abdominal cramps, diarrhea and leucopenia. CNS toxicity includes altered mental state and convulsions.
- **Dose**—it is given orally at a dose of 12 mg/kg/day for 14 days.

Carboplatin

- **Action**—it is a less reactive second generation platinum compound that is better tolerated.
- **Toxicity**—nephrotoxicity, ototoxicity and neurotoxicity are low. The dose limiting toxicity is thrombocytopenia and less often neutropenia.
- **Indications**—it is primarily indicated in ovarian carcinoma of epithelial origin, squamous cell carcinoma of head and neck, small lung cancer and *seminoma*.
- **Dose**—400 mg/m² as an IV infusion over 15-60 minutes to be repeated only after 4 weeks.

Pharmacology

The susceptibility of a tumor cell to drugs depends on the sensitivity of the tumor cells to action of the drug, whether the cell is in cycle or not and whether the drug reaches the cell at high enough concentration for a sufficient time to effect cell kill. The concentration of cytotoxic drugs at the tumor site, duration and integrity of its action are determined by several factors such as drug absorption, binding, distribution, metabolism, excretion tumor size and its vascularity. The higher dose is better in terms of response and relapse free interval and overall survival.

Principles of Treatment

Routes of Administration

The route of administration of a cytotoxic drug is determined by the stability, size, molecular charge and sclerosant characteristics of that drug. The intravenous route is most commonly used because a known concentration of the drug is delivered directly to the central component of the tumor.

Oral route is used infrequently because of the unpredictability of patient compliance and variable absorption of the drug. Subcutaneous and intramuscular route are rarely employed because of drug instability and the risk of thrombocytopenia and because large volumes of diluent therapy may be required to dissolve the drug. Intraperitoneal injection is beneficial for the drug delivered to small tumor nodules on the peritoneal surface, but maintenance of access is the major problem with this approach.

Combination Chemotherapy

Three general principles govern the use of combination chemotherapy. The drugs should be:

- Active against the tumor when used alone.
- Have different mechanism of action.
- Have minimally overlapping toxicities.

By using several drugs which attack the cells in different ways it is hoped that the development of resistant cells will be inhibited. If the above three guidelines are used then the dose chosen for each individual drug will be closed to that used when the drug is given as a single agent resulting in a minimum reduction in dosage intensity.

Schedule

The majority of intravenous drugs are given as intravenous injections or as a short infusion. Longer infusions may be preferable either to reduce the incidence of toxicity or to increase the efficiency.

Multimodality Treatment and Timing of Chemotherapy

At earlier stages of the tumor, the growth fraction is higher, spontaneous resistance may be less, tumor load is smaller and the drug penetrates a smaller volume greater, so chemotherapy is effective and preferred in early tumors. Before starting the treatment, prognostic factors for tumor type should be studied and the adjunct chemotherapy is selected. The chemotherapy given before the definite primary treatment is called as neoadjuvant chemotherapy. Its aim is to reduce tumor bulk to permit more radical local therapy. Radiotherapy may be combined with chemotherapy.

Toxicity

Many cytotoxic drugs are associated with side effects at commonly used therapeutic doses. Long term side effect of chemotherapy result in an increased risk of secondary malignancy and infertility in some cases.

Local Toxicity

Some cytotoxic drugs cause severe local reaction when extravasated, e.g. daunorubicin, mitomycin and mustine HCl. The use of trained personnel for injection of cytotoxic drugs reduces the hazards of administration.

Hematological Toxicity

Bone marrow suppression is the most important dose limiting toxicity. Myelosuppression is expected to be maximum in 10-14 days after treatment. Certain drugs such as mitomycin and nitrosoureas have a delayed nadir at 4-5 weeks. Hence, these drugs cannot be given more than once in week. Some of the alkylating agents have a cumulative effect on the bone marrow stem cells, e.g. chlorambucil, busulphan and melphalan. So the count may fall gradually for several weeks and recovery is slow.

Gastrointestinal Toxicity

The precise cause of nausea and vomiting which is commonly seen with cytotoxic drugs is uncertain; but it is probably due to a combination of stimuli from the chemoreceptor trigger zone. The timing of onset of vomiting varies and may occur within 2 hours. Prophylactic antiemetics are used to abolish vomiting and reduce nausea. Vinca alkaloids may cause constipation and paralytic ileus which will usually resolve spontaneously.

Alopecia

Generally, the head hair is lost but the whole of the body hair may be affected. The hair follicles are affected because of the high rate of cell turnover. Hair loss due to daunorubicin may be reduced by scalp cooling which by causing local vasospasm reduces the amount of drug reaching the follicles.

Pulmonary Toxicity

It is associated with only a few cytotoxic agents such as bleomycin, busulphan, cyclophosphamide and methotrexate. The pulmonary changes with infiltrate may be transient or may progress to pulmonary fibrosis.

Cardiac Toxicity

Cardiomyopathy may be seen with certain drugs. The exact cause is uncertain. Cardiac arrhythmias may be seen during or recently after the injection of daunorubicin.

Renal and Bladder Toxicity

Cisplatin may cause nephrotoxicity leading to fall in glomerular filtration rate and tubular dysfunction with subsequent hypocalcemia and hypomagnesemia. High doses of methotrexate may cause renal damage. The damage may be avoided by treating only those patients with satisfactory renal function.

Neurological Toxicity

The most common toxicity associated with cytotoxic drugs is peripheral neuropathy as seen with vinca alkaloids. Loss of tendon reflexes, paresthesia and numbness in the finger and toes may be noted only and are an indication to reduce the dosage. Development of myalgia, neuritic pain and peripheral sensory loss is an indication to stop the treatment. Drowsiness, confusion and encephalopathy may be seen with cyclophosphamide, procarbazine and *dacarbazine*.

Introduction

Viruses are the ultimate expression of parasitism. They take nutrition from the host cell and also direct its metabolic machinery to synthesize new virus particles. It consists of double stranded or single stranded DNA or RNA enclosed in protein coat called capsid.

Some viruses contain enzymes that initiate viral replication in the host cell. The whole infective particle is a virion. Their replication depends primarily on synthetic processes of the host cell. They not only take nutrition from the host cell but also direct its metabolic machinery to synthesize new viral particles.

Antiviral agents are most active when viruses are replicating. Viral replication consists of several steps like

- Adsorption to and penetration to susceptible host cells.
- Uncoating of viral nucleic acid.
- Synthesis of early regulatory protein/structural protein.
- Synthesis of RNA and DNA.
- Assembly/maturation of viral particles.

Drugs can potentially target any these steps, so antiviral drugs have to be specific for the different viral mechanism. In many viral infections, replication of virus peaks at or before the manifestation of clinical symptoms. To be effective, therefore, therapy has to be started in the incubation period, i.e. has to be prophylactic.

Action of Antiviral Drugs

Antiviral agents must either block viral entry into or exit from the cell or be active inside the host cell. Antiviral agents must inhibit virus specific directed nuclei rather than host cell directed nucleic acid. As nonselective inhibitors of virus replication may interfere with host cell function and produce toxicity, the search for chemicals that inhibit virus-

specific function is currently one of the most active areas of pharmacological investigation. Optimal efficacy, therefore, generally depends either on early initiation of therapy or on prevention of infection.

Classification

According to their therapeutic use

- *Anti-herpes virus agents*
 - Acyclovir
 - Idoxuridine
 - Gancyclovir
 - Trifluridine
 - Vidarabine
 - Pencyclovir
 - Famcyclovir
 - Valcyclovir
 - Foscarnet
- *Anti-retroviral agents*
 - Reverse transcriptase inhibitors
 - Zidovudine (AZT)
 - Didanosine
 - Zalcitabine
 - Stavudine
 - Protease inhibitors
 - Saquinavir
 - Indinavir
 - Nelfinavir
 - Ritonavir
 - Amprenavir
- *Anti-influenza virus agents*
 - Amantadine
 - Rimantadine
- *Nonselective antiviral agents*
 - Ribavirin
 - Lamivudine
 - Human interferon

Antiherpes Virus Agents

Acyclovir

Acyclovir is a synthetic purine nucleoside analogue. It is active against herpes group of virus (HSV-1 and HSV-2). Herpes simplex is the most sensitive to acyclovir followed by varicella zoster. Activity against Epstein-Barr virus, cytomegalovirus and human herpes virus-6 is comparatively weaker.

- **Mechanism of action**

- Antiviral drugs require virus specific enzymes for conversion to active metabolites that inhibits DNA synthesis and viral replication.
- Acyclovir in presence of herpes virus specific thymidine kinase is converted to acyclovir monophosphate which in presence of cellular kinase is converted to acyclovir triphosphate. This acyclovir triphosphate gets incorporated in viral DNA and stops lengthening of DNA strand and inhibits herpes virus DNA polymerase competitively.
- It is preferably taken up by the virus infected cells. Due to selective generation of active inhibitor in the virus infected cells and its greater inhibitory effect on viral DNA synthesis, Acyclovir has low toxicity for host cells.

- **Indication**

- *Herpes simplex mucocutaneous infection*—mucocutaneous H. simplex is a type 1 viral disease remains localized to lips and gums may be treated with acyclovir cream at least for 10 days. Oral lesions can be treated by applying oral suspension or tablet which dissolves in the oral cavity 4-5 times daily for 10 days. This treatment is most effective when new lesions are forming. Prophylactic oral therapy may prevent sun exposure related recurrences. Sometimes, disease often gets disseminated in immunocompromised individuals and may be treated with oral or intravenous acyclovir (15 mg/kg/day) for 7 days.
- *Ocular keratitis*—it is used as an alternative to idoxuridine drug, may be better for deep infections because of good corneal penetration. Eye ointments should be used 5 times daily till for 3 days after healing of corneal lesion.
- *Encephalitis H simplex*—acyclovir 10 mg/kg 8 hourly IV for 10 days is the drug of choice. Treatment will be effective if it is started early to avoid the mortality and neurological complication.
- *Genital herpes simplex*—genital infection can be treated by topical, oral or parenteral acyclovir depending on stage and severity of disease. In primary disease, 5% ointment is applied locally 6 times a day for 10 days is effective. In severe cases, they should receive oral

therapy (1 g/day in 5 divided doses for 7 days) in combination with local therapy. It gives symptomatic relief and rapid healing of lesion. In recurrent disease, topical therapy is quite ineffective. Most of the cases may be treated parenterally by 5 mg/kg IV infused over 1 hour, repeated 8 hourly for 10 days. Suppressive oral therapy with 200 mg 4 times a day prevents the recurrence as long as given.

- *Herpes zoster*—acyclovir is used in the dose of 5-10 mg/kg 8 hour IV for 7 days. Oral therapy is also beneficial if started early. It affords symptomatic relief and faster healing of lesion. Ointment may be applied on herpetic ulcers but postherpetic neuralgia is not prevented.
- *Chickenpox*—acyclovir (15 mg/kg/day for 7 days) is drug of choice. It reduces fever, eruptions, hastens healing and prevents visceral complication.
- *Shingles in immunocompetent person*—Acyclovir is used in the form of tablets or suspension. It gives best result within 48 hour of appearance of rashes. Severe symptoms may require IV administration.
- **Adverse effect**
 - Local reaction at the site of injection with inflammation, pain, phlebitis.
 - Stinging and burning sensation at the site of application
 - Headache, nausea, malaise.
 - Increase in blood level of urea and creatinine.
 - Renal impairment, acute renal failure.
 - Skin rashes
 - GIT disturbance, sweating, convulsions, coma.
- **Trade name**—CYCLOVIR, ZOVIRAX
- **Preparation**—Oral: 200, 400, 800 mg tablets. Topical: 5% ointment, 200 mg/5 ml suspension. Parenteral: powder to reconstitute for IV injection (250, 500 mg/vial).

Idoxuridine

It acts as a thymidine analogue. It was the first pyrimidine antimetabolite to be used as antiviral drug. It is primarily active against DNA virus.

- **Mechanism of action**—it competes with thymidine, gets incorporated into the DNA of virus. Therefore, it disrupts the DNA synthesis and the faulty DNA is formed which breaks down easily. This DNA directs the synthesis of wrong viral proteins (faulty transcription occurs). Clinical utility is limited to herpes simplex keratitis.
- **Indication**
 - *Ocular infection*—it is mainly used for ocular infections.
 - *Herpes simplex keratoconjunctivitis*—one drop of 0.1% solution is put hourly during daytime and 2 hourly during night. 0.5 % eye ointment may be applied

4 hourly for the period of 3 weeks in acute infection. Corneal ulcers respond well to this treatment and blindness can be prevented.

- *Adverse effect*
 - Systemic toxicity (bone marrow depression) is high after IV injections. So, intravenous infusions are avoided.
 - May develop the resistance readily to idoxuridine.
 - Ocular irritation, edema of eyelids, photophobia.
- *Trade name*—RIDINOX
- *Preparation*—topical: 0.1% eye drops, 0.5% eye ointments.

Gancyclovir

It is about 100 times more active against herpes viruses including cytomegalovirus. It is more active than acyclovir intracellular.

- *Mechanism of action*—gancyclovir requires triphosphorylation for activation prior to inhibiting the viral DNA polymerase. Activated compound competitively inhibit viral DNA polymerase and causes termination of viral elongation and inhibit the synthesis of DNA. As the concentration of active triphosphate is much higher inside CMV infected cell. Ganciclovir is much active against CMV, HSV, VZV, and EBV than that of acyclovir.
- *Indication:*
 - *CMV retinitis with AIDS patient*—IV ganciclovir 5 mg/kg every 12 hours for 2 weeks during induction and then 5mg/kg/day for maintenance therapy is useful. Dual therapy with foscarnet and ganciclovir has been shown to be more effective than either drug administered alone. Recently, ganciclovir intraocular implant which release ganciclovir into the vitreous cavity of eye is administered at the rate of 1.4 ug/hour has been proved for treatment of CMV retinitis. Surgical replacement is required at approximately 5 to 8 months intervals. Implant achieves high and prolonged intraocular levels of ganciclovir shown to delay progression of retinitis to a greater degree than systemic therapy.
 - *CMV colitis and esophagitis*—intravenous ganciclovir is used in AIDS patient.
 - *Before any organ transplantation*—IV administration reduces the incidence of symptomatic CMV disease if administered before organ transplantation.
 - *CMV pneumonitis*—in immunocompromised patient, it is often beneficial.
- *Adverse effect:*
 - Systemic toxicity: bone marrow depression.
 - Rash, fever, vomiting.
 - CNS disturbance: headache, seizures.
 - Neutropenia (20-40 % patient).

- *Trade name*—CYTOVENE, VITRASERT
- *Preparation*—Oral: 250 mg capsules. Parenteral: 500 mg/vial for IV injections. Intraocular implants: 4.5 mg ganciclovir/implant.

Famcyclovir

It is an ester prodrug of guanine nucleoside analogue of pencyclovir. It has good oral bioavailability. It has potency against herpes simplex virus and varicella-zoster virus. It is also inhibitory for hepatitis B virus.

- *Mechanism of action*—like acyclovir, famciclovir needs viral thymidine kinase for generation of active DNA polymerase inhibitor to block DNA synthesis. It is also inhibitory for hepatitis B virus.
- *Indication:*
 - *Alternative to acyclovir*—it is used as an alternative to acyclovir for genital herpes and herpes zoster.
 - *Recurrent orolabial HSV infection*—it is used in the dose of 500 mg twice a daily for 7 days.
 - *Shingles*—shingles which caused by herpes zoster is best treated with famcyclovir tablets in the dose of 500 mg every 8 hours for 7 days.
 - *Genital herpes infection*—orally drug 125 mg twice daily for 5 days is required. For recurrent genital herpes in immunocompetent patient, need 250 mg twice daily for upto 1 year.
- *Adverse effect:*
 - Headache, diarrhea, nausea.
 - Itching, rashes, mental confusion.
- *Trade name*—FAMTREX, FAMVIR.
- *Preparation*—Oral: 125, 250, 500 mg tablets.

Foscarnet

It is an inorganic pyrophosphate analogue; inhibit herpes viral DNA polymerase, RNA polymerase and HIV reverse transcriptase directly without activation of phosphorylation. Foscarnet is active against herpes virus, CMV and HIV at 3 µg concentration.

- *Mechanism of action*—drug act on the pyrophosphate binding sites of enzyme polymerase and reversibly blocks the site in a noncompetitive manner and inhibits cleavage of pyrophosphate from deoxynucleotide triphosphate.
- *Indication*—
 - *CMV retinitis*—in CMV retinitis with AIDS patient, 60 mg/kg every 12 hours for induction followed by 90-120 mg/kg/day for maintenance therapy.
 - *Acyclovir resistant mucocutaneous herpes simplex (type 2)*—40 mg/kg every 8 hours or 40 mg/kg every 12 hours yields good results.
 - *Varicella-zoster infection in AIDS patient*—it decreases HIV viral titer but not used primary for HIV infection.

It decreases HIV infection and produces moderate clinical improvement. Combination of zidovudine with foscarnet has been seen to be beneficial in HIV infected patient.

- *Adverse effect:*
 - Toxicity of foscarnet is high. Damage to kidney may produce renal diabetes like condition, acute renal failure.
 - Anemia, phlebitis, tremor, convulsions.
 - Neurological or constitutional symptoms due to hypocalcemia, alteration in PO_4 , K^+ , Mg^{++} .
- *Trade name*—FOSCAVIR
- *Preparation*—Parenteral: 24 mg/ml for IV injection

Antiretroviral Agents

These are the drugs active against human immunodeficiency virus (HIV) which is a retrovirus. They are mainly useful in prolonging life and postponing complication of AIDS or AIDS related complex but not fully cures the disease.

Reverse Transcriptase Inhibitors

Zidovudine Azidothymidine (AZT)

- *Mechanism of action*—cellular enzyme thymidine kinase phosphorylates zidovudine to a triphosphate. Triphosphate competitively inhibits viral RNA-dependent DNA polymerase (reverse transcriptase). Reverse transcriptase produce double stranded DNA copy. This DNA translocates to the nucleus and is integrated with chromosomal DNA of the host cell, which starts transcribing viral genomic RNA and mRNA. Viral regulatory and structural proteins are produced. Zidovudine itself gets incorporated into growing viral DNA and terminates chain elongation. Zidovudine thus prevents infection of new cells by HIV but, has no effect on virus directed DNA that has already integrated into the host chromosome. Zidovudine is effective against retrovirus only. Resistant to AZT can occur by point mutation which alters reverse transcriptase enzyme.
- *Indication:*
 - *AIDS or AIDS related complex*—the mortality and opportunistic infections are reduced by the use of zidovudine in the dose of 200 mg initially six times daily and thereafter, 500 to 1500 mg daily in 4-5 divided doses. In children over three months, 180 mg/sqm four times daily.
 - *Other AIDS associated diseases* such as thrombocytopenia, psoriasis, lymphocytic interstitial pneumonia, 100 mg cap, 300 mg tab to be taken with plenty of water.

- *Neurological diseases related to AIDS, Kaposi's sarcoma*—zidovudine reduces the manifestation and Kaposi's lesions do not appear.
- *Adverse effect*—anemia / granulocytopenia, CNS toxicity is mainly due to partial inhibition of cellular DNA polymerase. Nausea, anorexia, abdominal pain, headache, insomnia, myalgia at initial doses.
- *Trade name*—RETROVIR, ZIDOVIR
- *Preparation*—Oral: 100 mg capsules, 300 mg tablets, 50 mg/5 ml syrup. Parenteral: 10 mg/ml.

Didanosine and Zalcitabine

They belong to the group of dideoxynucleoside class of compounds.

- *Mechanism of action*—they act similar to zidovudine, that is, they inhibit reverse transcriptase after undergoing phosphorylation to generate triphosphate derivatives.
- *Indication:*
 - It is a good alternative to patients resistant to zidovudine.
 - Anti HIV efficacy of these drugs are comparable to zidovudine and hence, it is used in combination regime.
- *Adverse effect*—the most prominent dose related toxicity is pancreatitis and peripheral neuropathy. Diarrhea, abdominal pain, nausea.
- *Trade name*—Didanosine-DINEX, VIDEX. Zalcitabine-HIVID.
- *Preparation*—for didanosine—Oral: 25, 50, 100, 250 mg tab; 100, 250, 375 mg powder for solution; 2, 4 g powder for pediatric solution, for zalcitabine—Oral: 0.75 mg tab.

Protease Inhibitors

As these agent acts at the late stage of HIV replication, they are effective in both newly and chronically infected cells and thus, prevent the infection.

Ritonavir, Indinavir, Nelfinavir

These are specific inhibitor of HIV 1 and HIV 2. Protease must be consumed on an empty stomach for maximal absorption with good oral bioavailability. These drugs are protein bound.

- *Mechanism of action*—as protease enzymes encoded by HIV is involved in the production of structural protein and enzymes (including reverse transcriptase) of virus. These large viral polyprotein is broken into various functional component by this enzymes protease which acts at late step of HIV growing cycle, i.e. maturation of new virus particle. Protease inhibitor drugs bind to protease molecule and interfere with its cleavage function and produce immature noninfectious viral progeny. Hence prevents further round of infections.

- **Indication**—It is mainly used in HIV patients by following dose therapy:
 - Monotherapy with one of the drug in patient treated with AZT reduces HIV viral titre, increased CD4 cell count and improved clinical condition.
 - In PI resistant patient over month, combination of saquinavir with AZT or zalcitabine is more effective than double therapy.
 - Recently, PI in combination with two reverse transcriptase inhibitor (1 nucleotide +1 non-nucleotide) is recommended.
 - In booster dose, PI regimen containing both indinavir and low dose of zalcitabine along with reverse transcriptase inhibitors are quite effective.
- **Adverse effect**—gastrointestinal intolerance, asthenia, Headache, paresthesia, dizziness, rash, abnormal distribution of body fat, exacerbation of diabetes, crystaluria, and urinary calculi.
- **Trade name and Preparation**—Indinavir, INDIVAN, INDIVIR (400, 800 mg cap TDS), Nelfinavir—NELFIN, NEIVEX (250, 750 mg TDS), Ritonavir—RITOVIR (250, 600 mg BD)
- **Parkinsonism**—drug appears to act by promoting presynaptic synthesis and release of Dopamine in brain. It is used in milder cases, or in short course, in the dose of 100 mg bd gives good results.
- **Adverse effect**—Nausea, anorexia, insomnia, dizziness, nightmares, lack of mental concentration, hallucination, postural hypotension. Ankle edema due to local vasoconstriction.
- **Trade name**—AMANTREL, NEAMAN
- **Preparation**—Oral: 100,200 mg in elders and 5 mg/kg in children; 50 mg/5 ml syrup.
- **Precaution**—it should not be given to pregnant women and nursing mothers.

Nonselective Antiviral Agents

Interferon Alpha

They are low molecular weight glycoprotein. Interferon is produced endogenously as protective response to stimuli such as viruses, bacterial endotoxins and other intracellular microorganism. Interferon alpha and beta are produced by almost all cells against virus but interferon gamma is only produced by T-lymphocytes.

Anti-influenza Virus Agents

Amantadine

It is tricyclic amine which is unrelated to other antiviral drugs inhibit the replication of influenza A virus (A myxovirus)

- **Mechanism of action**—it has two mechanism of antiviral action. It inhibits viral replication at an early step, possibly uncoating and at late step in assembly mediated through altering hemagglutinin processing. Its target of action in influenza virus is the protein 'M₂' (integral membrane protein) acts as an ion channels. These drug interfere with the function of M₂ protein induces acid mediated dissociation of ribonucleoprotein complex in early step and potentiate acidic pH induces conformational changes in the hemagglutinin later in replication.
- **Indication:**
 - *In the prophylaxis of infection with influenza A virus*—it does not interfere with the antibody response to the influenza vaccination. So, both may be given together. If vaccine is given, amantadine can be stopped after two weeks. It is virus specific, influenza virus B is unaffected. It is given in the dose of 100 mg tablets daily for 7 days.
 - *Treatment of influenza illness*—it gives better result, if drug is given quickly just after the symptoms appear. 5 days' treatment is advised.
- **Mechanism of action**—interferon acts as immunomodulator, antiviral and antiproliferative agent.
 - Interferons are present at the site of infection before antibodies are produced, and its titre correlate with the virus act as host defense mechanism can prevent but not cures all the viral infection.
 - Interferon bind to specific cell surface receptors and affect viral replication at multiple steps like viral penetration, synthesis of viral mRNA and inhibit translation of viral protein and its release.
 - Interferon activates protein kinase enzymes and inhibits the viral protein synthesis by phosphorylation.
 - Interferon inhibits many RNA and DNA viruses, but they are host specific. Only interferon alpha has antiviral activity.
- **Indication:**
 - *Chronic hepatitis B and C*—high doses (10 MU) injected 3 cc. weekly for 6 months produce prolonged remission but relapse may occur. Addition of ribavarin to interferon alpha has the potential to further decrease the chances of relapse.
 - *AIDS related Kaposi's sarcoma*—36 million IV daily for 10-12 weeks IM or SC and maintenance dose is 36 million IV 3 times/weeks.
 - *Hairy cell leukemia*—induction dose is 3 million IV daily for 16-24 weeks SC or IM and maintenance dose is 3 million IV 3 times/weeks for 6 months.

Summary Chart						
Drugs	Trade name	Dose	Dosage form	Indications	Contraindications	Adverse effects
Idoxuridine	Ridinox	0.5 % ointment and 0.1% drops 4 hourly for 3 weeks	Ointment Drops	Keratoconjunctivitis	—	Ocular irritation , edema of lids, photophobia, bone marrow depression
Acyclovir	Zovirax Cyclovir Acivir DT	200 mg tablets for HSV infection 5 times daily for 7 days for HZV infection 800 mg 5 times daily 5% ointment-topical application 6 times daily	Tablet Injection i.v. Cream, Ointment	Genital herpes, Mucocutaneous herpes simplex, herpes zoster chickenpox, ocular keratitis	Hypersensitivity, glaucoma, Psychiatric disease Depression	Topical-stinging and burning sensation oral headache nausea malaise
Zidovudine (AZT)	Retonavir Zidovir	Adult 100, 500 mg /day in- 4 divided doses Children—180 mg/m ² 6-8 hourly. 50 mg/5 ml syrup	Capsule Tablet Syrup	AIDS	Low Hb level less than 7.5 g/deciliter, low neutrophil cell counts	Anemia, neutropenia, nausea, vomiting, abdominal pain, headache, insomnia and myalgia
Retrovir	Ritovir	250,500 mg bd	Capsule	AIDS Other AIDS related infection.	—	Rash, headache, GIT intolerance, abnormal distribution of body fat.
Amantadine	Amantrel, Neaman	Adult—100 mg bd, 200 mg OD Child— 5 mg/kg/day, 50 mg/5 ml syrup	Capsule Syrup	Prophylaxis of influenza. treatment of influenzal illness, Parkinsonism	Epilepsy, CNS disease, Pregnancy	Insomnia Dizziness Nightmares Lack of mental concentration and hallucination
Ribavirin	Ribavin Virazide	200 mg qid 50 mg/ 5ml syrup	Capsule Syrup	Influenza measles Hepatitis virus infection	—	Anemia Hemolysis, GIT symptoms
Interferon	Alferon, Realfa, viraferon	A vial (2 ml) 3,5,10 million IU/day	Injection- s.c and i.m	Chronic hepatitis. HSV, HZV, CMV, papilloma viral infection, Kaposi's sarcoma.	Severe allergies	Headache Dizziness Fever Lethargy

- *H. Simplex, H. zoster and CMV infection*—in immuno-compromised patient, it is used in the dose of 3 million IV /day or 3 times/weeks.
- Rhinoviral cold—intranasal interferon is prophylactic.
- *Condyloma acuminata caused by papillomas virus*—it is used by topical application on lesion. It can be used by an intralesional interferon injection in refractory cases.
- **Adverse effect**—
 - Flu-like symptoms: fatigue, rashes, pain, malaise, fever, visual disturbance
 - Neutropenia/ thrombocytopenia
 - Neurotoxicity: Numbness, neuropathy, tremor, sleepiness, convulsions.
 - Thyroid dysfunctions.
 - Hypotension, alopecia, liver dysfunction.
- **Trade name**—ALFERON, REALFA, VIRAFERON.
- **Preparation**—parenteral: 3,5,10 million IV vials for injections

Ribavarin

It is purine nucleoside analogue. It is active against both RNA, DNA viruses including myxoviruses, paramyxoviruses, adenoviruses, poxviruses.

- **Mechanism of action**—Ribavarin acts at multiple sites to inhibit viral replication. Ribavarin is phosphorylated intracellularly by enzyme adenosine kinase; generate its mono and triphosphate derivatives. It inhibits GTP and viral RNA synthesis.

- **Indication:**
 - *Viral bronchitis/viral pneumonia*—nebulized ribavirin is used in infants and children in the dose of 10 mg/kg/day QID. It can be administered IV and as an aerosol.
 - *Influenza*—Influenza A and B (measles in immunocompromised patient)
 - *Other disease*—it can also be given in acute hepatitis, herpes virus infection. In chronic hepatitis, it has been combined with interferon alpha.
- **Adverse effect:**
 - Anemia due to extravascular hemolysis when given orally/ intravenously.
 - Bilirubin and uric acid level are increased in plasma.
 - Long-term therapy causes CNS and GIT symptoms.
- **Trade name**—VIRAZIDE, RIBAVIN
- **Preparation**—Oral: 100, 200 mg capsules. 50 mg/5 ml syrup.
- The most commonly employed regimens are:
 - 2-NRTIs + 1-PI
 - 2-NRTIs + 1-NNRTI
 - 3-NRTIs
- Durability of these regimens depends mainly on adherence of the patient to it. Therapy should not be discontinued during an acute opportunistic infection, except in case of intolerance, interactions or toxicity.
- The 3 NRTI regimen has been less effective in patients with high (>100,000 copies of HIV-RNA/ml) initial viral loads is mostly used in less advanced cases.
- The NRTI + NNRTI PI is generally reversed for advanced disease or those with short life expectancy or repeated failures, because of risk of multiclass drug resistance and high toxicity.
- Four drug regimens have also been tested, but their superiority is not established.

Recent Advance Therapies

Highly Active Antiretroviral Therapy (HAART)

- HAART are combinations involving a protease inhibitor and other antiretroviral drugs—nucleoside reverse transcriptase inhibitors (NRTIs) and Non-nucleoside reverse transcriptase inhibitors (NNRTIs)—which have reduced the incidence of opportunistic infections.
- It has extended life substantially and decreased the infective load of HIV and other viruses.
- Orofacial disease caused by HIV infection has been significantly reduced by HAART.

Therapeutic Regimen

- Treatment should be aggressive (HAART) aiming at suppressing plasma viral load to undetectable levels (<50 copies of HIV-RNA/ml).
- Choice has to be made on the basis of efficacy, durability, drug interactions, impact on future options and cost.

Introduction

Corticosteroids due to their wide spread of action are widely employed in medical and dental practice. The adrenal gland consists of outer cortex that secretes steroidal hormones which have glucocorticoids, mineralocorticoid and weakly androgenic activities. Glucocorticoids action is mainly for hepatic glycogen deposition, while mineralocorticoid action is for sodium, electrolyte-fluid balance.

Corticosteroid Action and its Regulation

Natural adrenocortical steroids released by adrenal cortex are controlled by pituitary release of corticotropin (ACTH). Glucocorticoids are mainly required to adapt acute stress. It takes up to 1 year following cessation of corticosteroid therapy before the Hypothalamic-Pituitary-Adrenal axis (HPA-axis) recovers fully. Its production and synthesis are tightly regulated by central nervous system.

Diurnal fluctuation in the rate of release of ACTH regulates the rate of secretion of steroids. The rate of secretion of endogenous corticosteroids is maximum in early in the morning, declines during day time and reaches a minimum at midnight as the plasma level is being highest at about 6 AM. So it is better to administer corticosteroid usually early in the morning (in between 7 to 8 PM).

Exogenous administration of corticosteroid causes suppression of normal adrenal function is the potential side effect. So, the factor that must be considered in evaluating the degree of adrenal suppression are its anti-inflammatory potency, the dosage and duration of therapy.

Dosage above 20 mg Hydrocortisone for 5 days or longer causes adrenal suppression and prevents the physiologic release of glucocorticoid. So clinician looked for 'discontinuous' steroid therapy which retains the efficacy

at lower toxicity. Small dosages of steroids at frequent interval are needed to sustain elevated plasma corticoid level, i.e. to suppress ACTH secretion.

Prolonged use of steroid preparations can result in the (HPA axis) adrenal suppression or other adverse effect. So, dentist should be concerned with the patient undergoing long term steroid therapy above the physiologic level (>20 mg/day). Short term high dose therapy, alternate day therapy and topical administration produce minimal adrenal side effect and little adrenal suppression.

In long therapy where large dosage are employed, alternate day therapy is more effective and tolerable to patient due to less side effect, as there is recovery period between each dose is equally effective. When the drug has to be used in large dosage, short acting synthetic steroids with minimal mineralocorticoid effect is to be selected.

The placenta metabolizes hydrocortisone and prednisolone to the less active cortisone and prednisone. Unlike mother the fetus cannot convert cortisone and prednisone to hydrocortisone and prednisolone. By contrast dexamethasone and betamethasone cross the placental barrier to achieve high concentrations in the fetal circulation and can suppress the fetal HPA axis. Therefore in a pregnant woman needing treatment with a glucocorticoid, prednisolone should be used in preference to dexamethasone and betamethasone.

Classification

Glucocorticoids

- Short acting [biological half life less than 12 hours]
 - Hydrocortisone (cortisol)
 - Cortisone
- Intermediate acting [biological half life in 12-36 hours]
 - Prednisolone
 - Methyl prednisolone
 - Triamcinolone

- Long acting [biological half life more than 36 hours]
 - Paramethasone
 - Dexamethasone
 - Betamethasone

Mineralocorticoids

- Deoxycorticosterone acetate (DOCA)
- Fludrocortisone
- Aldosterone

Glucocorticoids

Mechanism of Action

Cellular Action

- *Activation of receptor*—corticosteroids penetrate the cells and bind to the specific receptor protein leads to activation of receptor in the cytoplasm of cell called as 'Human-Glucocorticoid receptor' resulting from structural changes in the protein.
- *Specific protein synthesis*—this receptor moves to nucleus, interacts with specific site on chromatin and induces transcription of specific mRNA results in specific protein synthesis. This process takes at least 30-60 min. Once appropriate proteins are synthesized, effect persists for long time.

Metabolic Action

- *Carbohydrate and protein metabolism*—they prevent conversion of amino acid into proteins i.e. antianabolic effect. They promote gluconeogenesis of new glucose formation in liver. Glucocorticoids stimulate gluconeogenesis and glycogen synthesis in the fastest state. Glucocorticoids increase the serum glucose level and thus stimulate the insulin release and inhibit the uptake of glucose by muscle cells.
- *Fat metabolism*—act directly- breakdown of Triglycerides to Fatty acids (lipolysis), Indirectly-formation and storage of fats (lipogenesis). It stimulates the hormone-sensitive lipase and thus lipolysis. The increased insulin stimulate lipogenesis and inhibit lipolysis leads to net increase in fat deposition and also increases release of fatty acid and glycerol into the circulation. Prolonged administration of glucocorticoids causes a redistribution of fat in the body, with loss from extremities and a deposition in the neck (buffalo hump) and supra-clavicular area and face (moon face). Hence, the release of amino acid from muscle catabolism, supply of glucose from gluconeogenesis, inhibition of peripheral glucose uptake, stimulation of lipolysis, all are contribute to maintain adequate supply to brain and body.

- *Calcium metabolism and bone*—glucocorticoids antagonize the action of vitamin D on the gut and reduce absorption of calcium. Given in large doses for prolonged periods, they interfere with the development of cartilage and inhibit linear growth in children.
- *Electrolyte and water metabolism*—it promotes sodium retention and potassium excretion

Anti-inflammatory Action

Glucocorticoid dramatically inhibits the manifestations of inflammation viz. edema, fibrin deposition, capillary dilatation, migration of leukocytes to the inflamed region and phagocytosis.

After glucocorticoid administration, changes are maximal at 6 hours and are dissipated in 24 hours are as follows:

- *Increases in neutrophils concentration*—It is due to increased influx of neutrophils from bone marrow into the blood and decreased migration from blood vessels leading to reduction in the number of cells at the sites of inflammation.
- *Decrease in lymphocytes concentration*—T lymphocytes are decreased more as compared to the B lymphocytes. Decrease in concentration of monocytes, eosinophils, basophils due to their movement from vascular bed to lymphoid tissue.
- *Inhibition of macrophage migration factor*—it inhibits the macrophage-migration inhibition factor, tumor necrosis factor, interleukin (IL-1,IL-2,IL-3,IL-6).
- *Reduction of prostaglandin*—it influences the inflammatory response by reducing the prostaglandin, leukotriene and platelet activating factor results from activation of phospholipase and decrease expression of cyclooxygenase.
- *Vasoconstriction*—it causes vasoconstriction when applied directly to the skin by suppressing the mast cell degranulation. It also decreases the capillary permeability by reducing the amount of histamine released by basophils and mast cells.

Other Effect

- *Catabolic action*—corticoids stimulate protein and RNA synthesis. They have catabolic action on lymphoid, connective tissue, muscle fats and skin.
- *Hemopoietic action*—glucocorticoids increases the hemoglobin and red cell content of the blood, but decreases the blood lymphocytes, eosinophils, monocytes, and basophils due to their redistribution rather than destruction. It causes an increase in polymorphonuclear leukocytes and platelet count in the blood.

- *Immunosuppressive action*—glucocorticoids do not significantly decrease the concentration of antibodies in the circulation and thus the individual exhibits normal antibody-antigen response. It prevents manifestations of humoral and cellular hyperimmunity. It inhibits the development of early step of immunity by disturbing the intracellular communication among the leukocytes or function of lymphocytes. It interferes with immune mechanism by influencing the function of macrophage by inhibiting tumor necrosis factor, interleukins.
- *CNS effect*—it maintains level of sensory perception and normal level of excitability of neurons. Pharmacological doses show mild euphoria. Large dosage of glucocorticone may increase intracranial pressure.
- *Gastrointestinal effect*—it increases the basal and nocturnal gastric acid secretion. It also aggravates peptic ulcer.
- *Anti allergic*—thymus derived lymphocytes are susceptible to the actions of corticosteroids so that cell immune responses are modified following their administration. Corticosteroids, thus, in large doses can cause lysis of the T cells, prevent homograft rejection and suppress cell mediated hypersensitivity reaction.
- *Suppress release of hormone*—it suppresses the pituitary release of ACTH, GH, TSH, LH.
- *Development of fetal lung*—important effect on the development of fetal lung like production of pulmonary surface active material which is required for air-breathing is stimulated by glucocorticoids.
- *DNA synthesis*—it inhibits cell division or synthesis of DNA.
- *Topical application*—topical application is found invaluable in many dermatological, oral, ocular and external ear conditions.
- *Diagnostic test*—dexamethasone suppression of adrenal function, cortisone test in hypocalcemia and prednisolone test to distinguish intra- and extra-hepatic obstructive jaundice.
- *Dental use*—corticosteroids because of their anti-inflammatory action are used in many oral diseases. Corticosteroids are used in the management aphthous stomatitis, pemphigus, erythema multiforme, lichen planus, oral submucous fibrosis, and sinusitis.
- *Miscellaneous*—it is used in a variety of conditions like Bell's palsy, infective hepatitis, encephalitis.

Precaution

- *History*—before starting the therapy, enquire about history suggestive of peptic ulceration.
- *Glucose estimation*—examine urine periodically for sugar.
- *Weight and blood pressure record*—keep record of weight and blood pressure.
- *Do not stop abruptly*—instruct the patient not to stop the therapy abruptly.
- *Increase dose*—if the patient develops an acute infection or has to undergo therapy, increase the dose of steroids.
- *Restrict use*—glucocorticoids must not be used in the presence of infection unless the latter can be simultaneously treated with antibiotics.

Hydrocortisone (cortisol)

It is naturally occurring steroid. It acts rapidly but has short duration of action.

Uses

- *Substitution therapy*—it is used as substitution therapy in Addison's disease and hypopituitarism.
- *Intensive short term therapy*—it can save life and reduce morbidity in certain potentially lethal conditions in which inflammatory or the metabolic response of the body itself threatens life. For example, allergic emergencies such as anaphylactic shock, status asthmaticus, acute necrotizing vasculitis, etc.
- *Prolonged high dose suppressive therapy*—it is indicated in acute rheumatic fever, ulcerative colitis, subacute hepatitis, autoimmune hemolytic anemia, pemphigus, ITP, Hodgkin's disease, etc.
- *Low dose chronic palliative therapy*—use of small doses of glucocorticoids as an adjunct to some other drugs like salicylates in rheumatic arthritis. Chronic suppression of pituitary ACTH secretion is indicated in congenital, virilizing adrenocortical hyperplasia.
- *Action*—anti-allergy, anti-inflammatory.
- *Therapeutic uses*—
 - *OSMF*—hydrocortisone injected intralesionally in the areas of fibrosis in dose of 25- 50 mg/ ml fortnightly. Topically, it is applied intraorally on the oral mucosa can be combined with orabase. Hydrocortisone 25 mg tablets in dose of 100 mg/day can be given systemically helps in relieving burning sensation. Hydrocortisone 25 mg tab. Can be combined with Dexamethasone 90 mg can be given at biweekly interval. It is mainly attributed to fibrinolytic, anti-allergic, anti-inflammatory action by decreasing fibroblastic production and deposition of collagen.
 - *Aphthous ulcer*—Topical application of steroid with Orabase is effective in case of aphthous ulcer. Presence of saliva may dilute drug and effectiveness. Intralesional injections of hydrocortisone acetate (25 mg/ml) into the mucosal lesion is given.

- *Desquamative gingivitis*—topical hydrocortisone cream and ointment (0.25- 0.5%) are applied intraorally to the affected lesion gives better result.
 - *Osteoarthritis*—intraarticular injections (25 mg/ ml) are indicated in acute inflammation. Repeated injections may be associated with painless destruction of bone joint.
 - *Addison disease*—cortisol is administered 20- 30 mg / day in divided doses usually 20 mg in morning and 10 mg in afternoon as best replacement therapy.
 - *Congenital adrenal hyperplasia*—hydrocortisone is given orally as 0.6 mg / kg dose in 2-4 divided doses.
 - *Lichen planus, pemphigus, and eczematous skin disease*—for oral lesions, topical application of creams and oral suspensions, ointment 1 % applied locally twice a day. Severe episodes of pemphigus require systemic steroid administration which may be life saving drug.
 - *Ulcerative colitis, Crohn's disease*—administered orally as a lower dose on alternate day with hydrocortisone 100 mg gives better results. Care should be taken in high doses as it may result in intestinal perforation.
 - *Shock, status asthmatics*—100 mg I.V bolus + 100 mg infusion in every 8 hrs may be given.
 - *Trade name*—CORTEF, EFCORLIN, WYCORT, ORABASE-HCA.
 - *Preparation*—Oral: 5, 10, 20 mg tablets. Topical: 1% eye drop-solution, 0.025 nasal drops and 0.25-2.5% skin creams, ointment.
- Hydrocortisone acetate*—Parenteral: 25, 50 mg/ml suspension for soft tissues intralesional/intraarticular inj.
- Hydrocortisone sodium phosphate*—Parenteral: 50 mg/ml for IV, IM, SC inj.
- Hydrocortisone sodium succinate*—Parenteral: 100, 250, 500, 1000 mg / vial for IV, IM injection.

Cortisone

It is next potent drug than hydrocortisone. Nowa days it is used very occasionally.

- *Action*—anti-allergy, anti- inflammatory.
- *Therapeutic uses*—
 - *Oral submucous fibrosis*—cortisone can be given orally in dose of 25 mg tablet. Inj.25 mg/ml can be given intramuscularly, gives better results.
 - *Addison disease*—Daily dose of 25-40 mg is given as a maintenance dose.
 - *Hodgkin lymphoma*—systemic use of cortisone in lower doses can be used. Thrombocytosis /Thrombocytopenia. Drugs can be used systemically.
- *Trade name*—CORLIN, CORTONE
- *Preparation available*—oral: 5, 10, 25 mg tablets. Parenteral: 22, 25 mg/ml of solution.

Prednisolone

It is four times more potent than hydrocortisone. It is most selective glucocorticoid.

- *Action*—it is mainly anti-inflammatory but, has little sodium retentive activity. It also used as an anti-allergic and immunosuppressive.
- *Therapeutic uses*—
 - *Rheumatoid arthritis*—initial dose of prednisone 10 mg / day is given in divided doses. Initial dose should be small and increases gradually until desired degree of control is achieved.
 - *Collagen disease*—collagen diseases like Polyarteritis nodosa, Granulomatous polyarteritis. Prednisone 1 mg/kg daily is given. If favorable results are not achieved, dose is increased in 20 mg daily and then reduced gradually to 5 mg/ week.
 - *Systemic lupus erythematosus*—prednisone used intramuscularly and intravenously. For oral use, topical application of prednisone 2-3 times daily can be used.
 - *Leukemia*—mainly in acute lymphoblastic leukemia, it is used as maintenance dose. It can be used orally for at least 2-3 years.
 - *Erythema multiforme*—prednisone gives in dose of 30 mg / day for several days and terminate after symptoms subsides. It is life-saving drug in severe form of erythema multiforme.
 - *Pemphigus*—prednisone is used topically mainly for oral lesions. Intralesional injections give better results to subside oral lesions. It is used systemically to bring the disease under control. After that, the dose is reduced. Mainly prednisone with immunosuppressive drugs like cyclosporine is effective in pemphigus.
 - *Bullous pemphigoid*—systemic prednisone with immunosuppressive drugs with dapsone is given in lower doses for shorter period of time.
 - *Behçet's syndrome*—systemic prednisone with immunosuppressive drugs is used in life threatening condition. It can be used to reduce ocular, oral, genital manifestation. Intralesional drugs are administered in mucocutaneous lesions. Topical application for oral mucosal lesion which is not controlled by systemic therapy.
 - *Rheumatic arthritis*—prednisone dose of 40 mg / day in divided doses is given.
 - *Bronchial asthma*—Oral administration of prednisone is also useful. prednisone of 40-60 mg is useful to control status asthmaticus and then withdrawn gradually. Recently, inhaled corticosteroids are found for the treatment of bronchial asthma.

- *Malignancies*—prednisone is most commonly used at the dose of 30 mg/ day gives symptomatic relief in advanced malignancies.
- *Post herpetic neuralgia*—prednisone 40-60 mg given orally is used daily for 1-2 weeks. Intramuscular and intravenous injections can be given in a patient with age more than 60 years. Other diseases like amyloidosis, cyclic neutropenia, purpura, urticaria, renal diseases.
- *Trade name*—DELTA-CORTEF, PRELONE, WYSOLONE, METICORTEN.
- *Preparation available*—oral: 5, 10, 20 mg tablets. 15 mg/5 ml syrups. 5 mg/ml suspension as pediatric drops. Parenteral: Injections of 25, 50 mg/ml for soft tissue, intramuscular, intralesional, intravenously.

Methyl Prednisolone

It is slightly more potent and more selective than prednisone.

- *Action*—anti-inflammatory, antiallergic, immunosuppressive.
- *Therapeutic uses*—same as that of Prednisolone. Initial effect of methyl prednisolone is for pulse therapy. It is mainly used for rheumatoid arthritis, renal transplantation and ulcerative colitis.
- *Trade name*—MEDROL, DEPOMEDROL.
- *Preparation available*—oral: 2 mg tablets. Parenteral: 20, 40, 80 mg/ml for I.M, I.V, Intralesional, intra-articular.

Triamcinolone

It is slightly more potent than prednisolone but highly selective glucocorticoids.

- *Action*—immunosuppressive, anti-inflammatory, hemopoietic action.
- *Therapeutic uses*—
 - *Lichen planus, oral submucous fibrosis, aphthous ulcer*—injections of 0.5 to 1 ml triamcinolone acetonide (10-20 mg/ml) directly into the mucosal lesions are usually repeated at different interval. Topical application of triamcinolone 0.1% ointment is applied intraorally 2-3 times a day on mucosal lesion gives relief in several days. But presence of saliva dilutes the drug and thus reduces the effectiveness.
 - *Bronchial asthma*—triamcinolone systemic dose of 40 mg given orally. Injections of 40 mg/ml are given IM.
 - *Rheumatoid arthritis*—for relief of painful symptoms in the joint. Intraarticular injections of triamcinolone 10 to 40 mg for large joints and 2 to 6 mg/ml for small joints are administered. intralesional injections may be given for mucosal lesions.

- *Ocular disease*—ocular lesions of interstitial keratitis, spring cataract, iritis are treated by topical triamcinolone 0.1% eye drops for every 4 hours in day time.
- *Osteoarthritis*—intraarticular injections are given in the dose of 20 mg/ml.
- *Purpura*—in adults, triamcinolone 40 mg/ml is given intramuscularly until the platelet level rise to normal than tapered until the drug is withdrawn.
- *Contact cheilitis, exfoliative cheilitis, plasma cell cheilitis, granulomatous cheilitis*—triamcinolone is applied topically (0.2%) gives symptomatic relief. Repeated intralesional injections into the lips may give better result in very few weeks.
- *Benign mucous membrane pemphigoid*—topical or intralesional steroids injections are helpful.
- *Hemangioma*—intralesional and intramuscular injections of steroids are administered for better results. Injections are usually given at different intervals. It is commonly combined with immunosuppressive drugs are given in increasing frequency as it may cause hyperglycemia and osteoporosis by using single dose.
- *Trade name*—KENACORT, KENALOG, LEDERCORT, ARISTOCORT, ATOLONE
- *Preparation available*—Oral: 1, 4, 8 mg syrup. Topical: 0.1% eye drops, skin ointment. Parenteral: 3, 10, 40 mg/ml for I.M, intraarticular, intralesional injections.

Dexamethasone

It is very potent and highly selective glucocorticosteroids. It is mainly used for adrenal cortical suppression. Dexamethasone has no adverse effect on fluid retention and in hypertension.

- *Action*—immuno-inflammatory, Antiallergic
- *Therapeutic uses*—
 - *Allergic diseases, serum sickness, urticaria, hay fever, contact dermatitis, angio-neurotic edema*—dexamethasone 24 mg is administered IV. Topical application by using skin ointments on affected areas 2-4 times a day.
 - *Benign migratory glossitis*—used by topical application on affected tongue 4-5 times a day.
 - *Ocular diseases*—in case of inflammatory and allergic conditions of eyes, dexamethasone ointments, 1% eyedrops, every 4 hours in day time and at bed time.
 - *Shock, cerebral edema*—dexamethasone is mainly used in the dose of 24 mg/ml IV infusion and IM injections because this drug has fluid retention capacity. Topically can also be used.
- *Trade name*—DECADRON, DECADRON-L, WYMESONE.

- *Preparation available*—oral: 0.25, 0.5, 0.75, 1, 2, 4, 6 mg tablets. Topical: 0.1% eye drops, ear drops, skin ointments. Parenteral: 4, 8, 10, 20 mg/ml for IV, IM, intralesional and intra-articular injections. To give IV, only 24 mg/ml suspension is used. And for intraarticular injections, 16 mg/ml suspensions are used.

Betamethasone

- *Action*—this drug has similar action that of dexamethasone.
- *Therapeutic uses*—same as dexamethasone. It is mainly preferred in cerebral edema and shock.
- *Trade name*—Celestone, Betnovate, Betnesol, Betnelan.
- *Preparation available*—oral—oral drops 0.5 mg/ml, tablets 0.5-1 mg. Topical—0.1% eye drops, ointments, 0.05% nasal drops, 0.12% skin creams. Parenteral—4 mg/ml for IM, IV, intralesional and intraarticular.

Adverse Effects of Glucocorticoids

Long terms administration of glucocorticoids can cause adverse effects. These are deposition of fat in cheeks, shoulders, edema and weight gain, osteoporosis, acne, hypertension, striae/Bruises, diabetes, glycosuria, peptic ulcer, growth retardation mainly in children, delayed wound healing and adrenal suppression.

Contraindication

- *Cushing syndrome (absolute contraindication)*—most patients who are given daily doses of 100 mg of hydrocortisone of longer than 2 weeks undergo series of changes termed as cushing syndrome. It is characterized by fat deposition, rounding appearance of faces (moon facies), weight gain, muscle wasting, thinning of the skin with striae and bruising, hyperglycemia, development of osteoporosis, diabetes and impaired wound healing.
- *Diabetes mellitus*—steroid containing fluorine intensifying diabetes more than other and so it should be avoided in diabetes.
- *Hypertension*—it increases intracranial hypertension due to hypokalemia, hypochloremic alkalosis, there is increased in blood pressure.
- *Pregnancy and lactation*—it is best to avoid in 1st trimester of pregnancy due to risk of cleft palate and intrauterine growth retardation in the fetus.
- *Peptic ulcer*—risk of bleeding and silent perforation of ulcers may occur. Dyspeptic symptoms are frequent with high dose therapy.
- *Osteoporosis*—it appears to antagonize the effect of vit.D on calcium absorption and on hemopoietic system, increase in the number of platelets and red blood cells.

- *Glaucoma*—steroid increases the intraocular pressure.
- *Heart disease like CHD*—sodium retention action of corticosteroid may aggravate the CHF.
- *Herpes simplex infection*—corticosteroid are only palliative, do not remove the cause of inflammation. It favors the spread of infections as the capacity of defensive cells to kill microorganisms is impaired.

Caution

Glucocorticoids should be used cautiously in pregnancy, tuberculosis, epilepsy, in debilitating and other patients.

Newer Drugs

- *Budesonide (TN: Budecort)*—preparation available-topical 100,200,400 mcg/puff inhaler. It is used mainly in chronic bronchial asthma. Used inhalation in the dose of 200-1600 mcg/day in adults and 200-800 mcg/day in 2-4 divided doses in children.
- *Clobetasol (TN Emosone)*—preparation available-topical 0.05% ointments, lotion, gel. It is used in dermal infections by topical application on skin 2-4 times a day.
- *Fluocinolone (TN: Flucort 0.05%)*
- *Fluticasone (Flixotide 25, 50 mcg/puff inhalers)*—it is new inhaled steroid with high inflammatory activity and negligible systemic absorption. It is used as aerosol 2 times a day for prophylaxis of asthma.
- *Halocinonide (TN: Clobederm-H 0.025 to 0.1%)*
- *Mometasone (TN: ELOCON 0.1%)*—they are newer drugs used mainly for dermal infections twice a day on affected skin.

Mineralocorticoids

Important mineralocorticoids are aldosterone, fludrocortisone, desoxycortisterone.

Mechanism of Action

Mineralocorticoids have main effect on electrolyte (sodium, potassium) and fluid balance.

They have sodium retaining and potassium depleting action. Hence, it influences the salt and fluid water equilibrium in the body. Mineralocorticoids act by binding to the receptors present in the cytoplasm of principal cells forming drug-receptor complex which activate the series of events similar to described for glucocorticoids. It increases reabsorption of sodium and secretion of potassium by electrolyte and water metabolism.

Single dose of aldosterone produces sodium retention and increased urinary loss of potassium. As a result of

aldosterone deficiency the renal tubules are unable to conserve sodium.

Desoxycortisone Acetate (DOCA)

It has mainly mineralocorticoid activity. It serves as precursor of Aldosterone.

- *Action*—sodium and potassium balance retaining action.
- *Therapeutic use*—
 - *Hypoaldosteronism*—it is given systemically by intramuscular injection at weekly interval in dose of 20 mg/ml.
 - *Severe postural hypotension*—as this drug has sodium retaining action, it cures the manifestations in short period of time by using sublingual administration of DOCA in the dose of 2-5 mg/day.
 - *Addison disease*—2-5 mg sublingually, 10-20 mg intramuscularly once or twice a week is quite effective in Addison's disease. It can be given as replacement therapy.
- *Trade name*—Percorten
- *Preparation available*—Oral: 2-5 mg sublingually. Parenteral: 5, 10, 20 mg/ml IM.

Fludrocortisone

It is more potent mineralocorticoid having some glucocorticoids action.

- *Action*—sodium retention action. Anti-inflammatory action only at high doses.
- *Therapeutic uses*—
 - *Addison's disease*—0.1mg tablets are used as initial doses; gradually dose is reduced to 0.1 to 0.2 mg daily as maintenance dose. It is used to replace the Aldosterone.
 - *Autonomic neuropathy*—fludrocortisone is drug of choice for autonomic neuropathy. It is used to achieve vasoconstrictor tone. It is used in the dose of 0.5 to 1 mg/day.
 - *Hypotension*—as the drug has sodium retention capacity. It is used mainly in hypotension.
- *Congenital adrenal hypoplasia*: Tablets of 0.1 mg/day is used because in such patients, salt resting is comparatively more.
- *Trade name*—Florinef
- *Preparation available*—Oral: 0.1 mg tablets.

Adverse Effect

- Edema
- Hypokalemia
- Progressive rise in blood pressure
- Fluid and electrolyte balance disturbance

- Systemic hypotension
- Weight gain.

Contraindication

- Hypertension
- Systemic heart diseases
- Osteoporosis
- Cushing syndrome.

Dental Consideration

- *Physician consultation*—it is preferable to consult patient physician before carrying out any dental treatment in patient on steroid therapy to determine any alteration required in the dose before dental treatment.
- *Osteoporotic changes*—patient receiving long term steroid therapy results in adrenal suppression causes osteoporotic changes in jaw bone and degenerative changes in periodontium. So; dentist should look for such symptoms.
- *Stressful condition*—patient may show hypotension, vomiting, glucose intolerance, arthralgia in stressful conditions. In such conditions, majors should be taken to support blood pressure, fluid volume and to maintain normal electrolyte balance.
- *Minimum stress dental treatment*—dental treatment should be carried out with minimum stress. Minor dental procedure like minor restoration, minor biopsy, denture orthodontic adjustment, scaling and prophylaxis may not required any alteration in the dose of corticosteroids.
- *Doubling the dose*—for moderate stressful dental procedure in suppressed patients, normal dose should be doubled 8 hours before the procedure like 3rd molar impaction, vertical extraction, incision and drainage of dental infection. The dose should be tapered back to normal during post operative period after the cessation of pain, fever and other symptoms of stress.
- *Major dental surgery*—for major dental surgery under general anesthesia, due to facial trauma, severe oral infection and Orthognathic surgery, parental administration of corticoids 100 mg cortisol intramuscularly 8 hours before the procedure followed by intravenous infusion of hydrocortisone (300 mg cortisol) during procedure is given.

Desensitizing Agents, Gum Paints and Mouthwashes

Dentinal Hypersensitivity

Introduction

It is certain that the teeth of man have been hurting for many thousands of years. Pain has been so closely associated with dentistry that the word “pain” and “dentistry” have almost become inseparable and one of the most important objective of dentistry has been the control and elimination of the pain.

Clinical experience suggests that dentin hypersensitivity is a relatively common cause of pain associated with the teeth. Despite this, the condition has been justifiably described as “an enigma” being frequently encountered but ill understood. Even the suitability of the term “dentin hypersensitivity” may be questioned. Such symptoms as sharp, painful, responses of short duration are associated with many conditions in which dentin is exposed including the dental caries. Furthermore, there is no evidence to indicate that “hypersensitive” dentin differs in any way from normal dentin (or that specific pulpal changes occur). The term “dentin sensitivity” may be more appropriate. The international association for the study of pain (IASP) termed hypersensitivity as “allodynia” which is pain resulting from a non-noxious stimuli to normal skin and hence, it can be appropriate to call dentinal hypersensitivity as “*allodontia*”.

Prevalence of Dentinal Hypersensitivity

- *Incidence*—the prevalence of dentinal hypersensitivity has been reported over the years in a variety of ways: Cross Sectional Surveys have shown dentinal hypersensitivity to be ranging anywhere in between 8%-57% of adult dentate population and up to 30% of adults at some time during their lifetime. *It is claimed that 14.3% of all dental patients have some degree of dentin hypersensitivity.*

- *Age group*—dentinal hypersensitivity has been shown to peak in 20 to 30 year olds and then rise again when in their 50's. The condition generally involves the facial surfaces of teeth near the cervical aspect and is very common in premolars and canines.
- *More common in periodontal patient*—72-98% of the periodontal patients suffer from dentin sensitivity due to loss of attachment and exposure of root surface. Patients undergoing periodontal treatment are particularly susceptible to this condition because of the recession following periodontal surgery or loss of cementum following non-surgical periodontal therapy.
- *More common in females*—females are more commonly affected than males as females because of esthetic reasons, females tend to brush their teeth more vigorously than males.
- *More common on facial surface*—the condition generally involves the facial surfaces of teeth near the cervical aspect and is very common in premolars, canines and second premolars.
- *More common on left side*—left side of the arch is more commonly affected than the right side of arch (Right-handed tooth brushers tend to use more force on left buccal surfaces).

Definition

Short, sharp pain arising from exposed dentin in response to thermal, evaporative, tactile, osmotic or chemical stimuli which cannot be ascribed to any other form of dental defect or pathology.

Common terminologies used for hypersensitivity are *dentin sensitivity, dentin hypersensitivity, dentinal hypersensitivity, cervical hypersensitivity/sensitivity, root hypersensitivity/ sensitivity, and cemental hypersensitivity/ sensitivity.*

Mechanism of Dentin Sensitivity

The dental pulp is richly innervated by variety of nerve fibers. (Only a few of the 1000 to 2000 nerves found in each tooth reach dentin). Pulp is richly innervated by both myelinated (A fibers -25%) and unmyelinated (C fibers -75%)—both are responsible for sensitivity of dentin. According to conduction velocity, the nerve units are classified into:

- *A fibers*—they are having conduction velocity of more than 2 m/sec. A fiber responsible for dentin hypersensitivity. They induce sharp pain in teeth.
- *C fibers*—they are having conduction velocity of less than 2 m/sec. C fibers activated only when stimulus reaches the pulp proper (intense heating). It may play a role in mediation of dull radiating pain associated with pulpal inflammation.

Causes and Clinical Features of Dentin Hypersensitivity

- *Causes*—dentin exposure due to loss of enamel from the crown of the tooth or denudation of the root surface by loss of cementum and overlying periodontal tissues. Factors responsible for it are enamel loss, occlusal wear (attrition), tooth brushing (abrasion), dietary erosion, parafunctional habit, loss of cementum, denudation of root surface (gingival recession), chronic periodontal disease, following periodontal surgery, tooth abnormally positioned in arch, root preparation, leaching margins of restorations. Improper oral hygiene technique and dental caries.
- *Symptoms* –
 - The chief symptom is a sharp, sudden pain of short duration, although some patients complain of dull, lingering sensitiveness.
 - Sensitivity to cold, but pain may also be elicited by the use of toothpick and or brushing.
 - In some cases, hot liquids and sweet or sour foods may evoke a response. Although most teeth are sensitive to more than one stimulus, not all hypersensitive teeth respond to the stimulus.

Theories of Dentinal Hypersensitivity

Transducer Theory

According to this theory the “synaptic like” relationship exists between the terminal nerve endings and the odontoblastic process.

But if true synapse were present between these two elements to facilitate the transmission of dentinal sensation then neural transmitting substance such as acetylcholine would be expected in this area of the odontoblastic process

and the predentin. There is no direct evidence for the presence of acetylcholine activity in the neural transmission in the pulp.

Modulation Theory

On any irritating stimulus to the dentin, the odontoblasts may become injured and subsequently release a variety of neurotransmitting agents as well as vasoactive and pain producing amines and proteins.

These substances may modulate associated nerve fiber action potentials by increasing neuronal clamp levels through cell membrane adenylate cyclase receptors.

Odontoblastic Transduction Theory

Odontoblasts are neural crest in origin. This theory assumed that odontoblasts extend till the periphery of the dentinal tubules and the stimuli excites the odontoblastic process.

The membrane of odontoblasts may come in close apposition with that of nerve endings in the pulp or in the dentinal tubule. These odontoblasts transmit the excitation to these nerve endings but odontoblastic process extends only part way through dentin and odontoblast membrane potential is too low to permit transduction.

Gate Control Theory and Vibration

According to this theory, the medullated nerves, i.e. A-delta fibers, can accommodate the vibrations without getting excited but unmyelinated nerve fibers, i.e. C-fibers, cannot accommodate such vibrations and get stimulated unproportionately leading to sensitivity.

Hydrodynamic Theory

It is the most widely accepted theory till date. In 1966, Branstromm provided the scientific explanation for hydrodynamic theory. Most dentinal stimuli cause pain by generating action potentials in intradental nerves through a hydrodynamic mechanism.

Application of any stimuli to dentin increases the rate of fluid flow in dentinal tubules (**Fig. 46-4**). The fluid flow in turn excites nerve terminals at the inner ends of the tubules or in the outer layer of the pulp. (Exceptions to this are electric current and intense cold, which can stimulate pulpal nerves directly).

Treatment of dentin hypersensitivity aims to interrupt this sequence of event by:

- *Creation of tubular plug*—providing a chemical ion that can react with and precipitate one of the components of the protoplasmic fluid and thus create a tubular plug.
- *Sealing of dentinal tubules*—sealing or physically occluding the outer end of dentinal tubules.

Fig. 46-1: Excitation of sensory nerve ending of dentin can cause the dentinal hypersensitivity.

Fig. 46-2: Heat—slow inward movement of dentinal fluid.

Fig. 46-3: Dehydration, cold and hypertonic solutions—outward movement of dentinal fluid.

The displacement occurs in either on outer or inward direction (**Figs 46-1 to 46-3**) and their mechanical disturbance activates the nerve endings present in the dentin or pulp.

Question to be asked for Diagnosis of Hypersensitivity

- History and nature of pain

Fig. 46-4: Increase fluid flow in dentinal tubules.

- The number and location of sensitive teeth
- The area of tooth from which the sensitivity originates
- The intensity of pain
- The trigger of stimulus which initiates sensitivity
- The frequency and duration of each episode
- Recent restorative, periodontal and hygiene treatment change in diet or oral hygiene aids or home bleaching.

Differential Diagnosis of Dental Hypersensitivity

- Abscessed or non-vital tooth
- Cracked tooth syndrome
- Dental caries
- Diet sensitivity
- Genetic sensitivity
- Restorative sensitivity (Open or defective margins of restoration, fractured restorations)
- Bruxism
- Medication sensitivity
- Bleaching sensitivity
- Barodontalgia
- Gingival and periodontal pain
- Non-oral cause of dental pain like neurological causes, sinus pathology and psychogenic causes and atypical facial pain.

Clinical Examination for Diagnosis of Dental Hypersensitivity

- Tactile examination
- Air flow from air-water syringe
- Percussion
- Biting pressure

- Duration of pain after stimulus
- Radiography
- Gingival recession, loss of attachment, enamel loss
- Cracked cusps, fractured or leaking restoration, occlusal interface, hyperfunction.

Methods of Measuring Tooth Hypersensitivity

To measure the sensitivity of tooth, following methods can be used. These are mechanical, chemical, electrical, evaporative, thermal, osmotic, verbal rating scale and visual analog scale.

Mechanical (Tactile Stimuli)

- *Instrument*—it is done by explorer or probe. Constant pressure by probe (yeaple), mechanical stimulator and scaling procedure.
- *Identification of area of sensitive dentin*—all clinicians use a dental explorer to identify regions of sensitive dentin. To understand how movement of an explorer across dentin can cause a hydrodynamic stimulus, one must consider the following.
- *Applying the force*—although the use of a gentle force of 5 to 10 gm on the explorer seems as though it would be a trivial stimulus, that force is localized on the tip of explorer which is about $500 \mu\text{m}^2$. This is sufficient to overcome the elastic limit of dentin, leading not only to compression of dentin and smear layer creation under the explorer tip but also to permanent (yet microscopic) deformation of dentin (scratch development). You should lightly pass a sharp dental explorer over sensitive area of a tooth and grade the response of patient on scale
- *Results*—results of sensitivity test is as follows:
 - 0—no pain is felt
 - 1—slight pain or discomfort
 - 2—severe pain
 - 3—severe pain that lasts
- *A yeaple probe*—it is a compact handpiece that contains an explorer line in an adjustable electromagnetic field. The force should be applied to the same area at 90° to the surface in a static inwardly directed manner. The patient is asked to response whether there is pain or no pain at each test. The instrument is adjusted in 5-10 gm increments from 10-70 gm. Each increasing force compress more and more dentin. People who are more sensitive tend to react with pain at lower forces than people who are not sensitive or those who are desensitized.
- *Chemical*—it is done by hypertonic solutions like NaCl, Glucose, sucrose, CaCl_2

Electrical Stimuli

- *Instrument*—it includes electric pulp tester and dental pulp stethoscope. Pain response can be obtained from non-sensitive as well as from sensitive teeth.
- *Mechanism*—dentinal fluid movement is not necessary for transmission of electrical stimulus, rather the presence of lower resistance organic material in cementum, enamel or dentin. Sensitive teeth show lower pain thresholds than healthy teeth.
- *Technique*—electrode or probe should apply the electrical stimulus to tooth. Power source is required to vary the electrical stimulus and means of completing the electrical circuit.
- *Reference electrode*—reference electrode, a saliva ejector connecting the patient to a pulp stimulating instrument—pulp stethoscope.
- *Current applied*—electrical stimulus consisting of a direct current pulsed voltage between 0 and 150 or 0 and 300 volts.
- *Placing of probe tip*—place the probe tip on the tooth surface, depress on/off switch. Rotate the ramp adjustment dial. Intensity of electrical stimulus rises from 0 to 25 rms volts and above patient feels the pre-pain (signals the operator to remove the probe that activates the recorder).
- *Evaporative stimuli*—it includes cold air blast, air thermal system, air jet stimulator, temtronic device (microprocessor temp. Air delivery system)

Thermal Stimuli

It is electronic threshold measurement device, cold water testing and heat.

- *Why cold stimuli is used*—because patient are generally more sensitive to cold than to hot stimuli, the use of cold water (10, 15, 20, 25, 30°C) as a simple, quantitative stimulus is gaining in popularity.
- *Mechanism*—thermal stimuli are effective of differences in thermal conductivity and coefficient of expansion or contraction of fluids and their container, enamel and dentin. Thus application of cold causes more rapid volumetric contraction of dentinal fluid that occurs in the dentin. This mismatch of volumetric changes produces negative intrapulpal and intradental pressures that displace mechanoreceptors and cause pain. Heating has the opposite effect but the same result, pain clinically, cold stimuli are more useful than hot stimuli for testing dentinal sensitivity. Patients tolerate cold stimuli better than hot stimuli, and there is danger of causing pulpal damage.
- *Isolation of tooth*—in using cold water, each tooth is isolated with a rubber dam and water at a known temperature.

- *Flowing of water*—water is slowly flowed on the exposed dentin surface for a maximum for 3 seconds from a disposable plastic syringe.
- *Reaction of patient*—the patient is forced to decide if that temperature causes pain or not and then the next lower temperature. It is tried until the patient responds unequivocally.
- *Air burst method*—another method which can be used is directing a burst of air (room temperature) from a dental syringe onto the tooth to be tested. Room temperature is cooler than the tooth and cooling by this method can be easily detected as pain if the teeth are sensitive or parallel. 1 second blast from the air syringe, temperature between 65 and 70°C and pressure of 60 psi at right angle to the tooth near CEJ or exposed root surface is used.

Osmotic

It is subjective pain to a sweet stimulus.

- *Solution used*—fresh saturated solution of sucrose; allowing it to reach room temperature.
- *Application*—a cotton applicator saturated with the solution applied to the root surface, allowed to remain for 10 seconds.
- *Results*— no pain—0
and pain –1.

Verbal Rating Scale (VRS)

It presents a restrictive choice of words that may not represent the pain experience with significant precision for all patients (Huskinson 1974). Keel [1948] described a four point scale grading pain as slight, moderate, severe and agonizing. More recently, modification of this type of pain scale has been reported and are as follows:

- *Hansen 1992*—simple binary pain scale- pain before the treatment/no pain after the treatment.
- *Gilliam and Newman 1993*—it is as follows
 - 0 = no discomfort
 - 1 = mild discomfort
 - 2 = marked discomfort
 - 3 = marked discomfort that lasted 10 sec.
- *Gedalia et al 1987*
 - 1 = no pain
 - 2 = discomfort only
 - 3 = pain
 - 4 = severe pain
 - 5 = unbearable pain
- *Thrash et al 1992*—
 - 0 = no significant discomfort
 - 1 = discomfort, but no severe pain
 - 2 = severe pain during application of stimulus
 - 3 = severe pain during application and continuing after application of stimulus.

- *Schiff et al 1998* (Schiff's cold air score)
 - 0 = tooth/ subject does not responds to air stimulus
 - 1 = tooth/ subject responds to air stimulus but does not request discontinuation of air
 - 2 = tooth/ subject responds to air stimulus and requests for discontinuation of air stimulus or moves away from stimulus.
 - 3 = tooth/ subject responds to air stimulus considers stimulus to be painful and requests for discontinuation of stimulus.

Visual Analog Scale (VAS)

A Visual Analogue Scale (VAS) is a measurement instrument that tries to measure a characteristic or attitude that is believed to range across a continuum of values from none to an extreme amount of pain.

Method

Ask the patient to indicate on the line where the pain is in relation to the two extremes. Ask the patient to mark on the line the point that they feel represents their perception of their current state (**Fig. 46-5**). The VAS score is determined by measuring in millimeters from the left hand end of the line to the point that the patient marks. When the VAS is properly explained to subjects, they can easily understand its use and successfully use it to indicate their level of pain response to hypersensitive stimuli.

- *Comparison between VAS and VRS*—the VAS should be the more appropriate device than the VRS for measuring levels of sensitivity, pain during subject assessment and for measuring tactile and thermal stimuli of hypersensitivity. For those unable to read or to understand the linear visual analogue scale, picture of faces showing increasing distress can be used (**Fig. 46-5**).
- *Advantage of VAS*—VAS is found to be reproducible therefore a very high correlation between successive measurements of pain severity has been noted.

Fig. 46-5: Visual rating scale is used to determine current state.

- *Disadvantage*—disadvantage of visual analog scale is that patient tends to spread their responses over the entire scale regardless of the magnitude of the actual sensation.

Treatment of Hypersensitive Dentin

Treating dentinal hypersensitivity can be challenging for the dental professional because of the difficulty related to measuring the pain response since the response varies from patient to patient. In addition if the dentin exposure is due to personal habits, it may be difficult for patients to change their behavior(s). If the diagnosis confirms dentinal hypersensitivity in the absence of underlying diseases or structural problems, then the following steps can be initiated:

- Remove the risk factors by educating the patient about dietary acids and other oral care habits;
- Recommend different toothbrushing methods, if appropriate;
- Initiate treatment by recommending a desensitizing agent for home use; or
- Applying topical desensitizing agents professionally. Grossmann's ideal requisites for a desensitizing agent.
 - *Non irritant*—it should be non-irritant to the pulp.
 - *Painless*—it should be relatively painless on applications
 - *Easy application*—application of desensitizing agent should be easy.
 - *Action*—action should be rapid.
 - *Long term effect*—effect of desensitizing agent should be long term.
 - *No staining*—no staining of tooth should not occur.
 - *Consistency*—desensitizing agent should be consistent in effectiveness.

Traditional Treatment of Dentinal Hypersensitivity

Home care with dentifrices

- *Potassium nitrate dentifrices*—Thermoseal, Thermoseal RA, Thermokind-f, Sensicure k, Sensodent-k, Sensodent-kf, Promise, S
- *Senquel-f, Nitra, Denquel, Sensodyne.*
- *Potassium oxalate dentifrice*—Protect.
- *Sodium fluoride dentifrices*—Thermodont, Thermoseal, Colgate, Thermodont, Proevident.
- *Sodium citrate dentifrices*—Protect
- *Sodium monofluorophosphate dentifrices*—Colgate, Thermokind-f, Senquel-f, Sensicure, Nitra, Sensicure k, Aquafresh, Pepsodent, Sensodent-k, Sensodent-r.
- *Stannous fluoride dentifrice*—Colgate gel, Colgate flourigard, Cibacca fluoride
- *Calcium chloride*—Forhan's
- *Calcium carbonate*—Colgate, Meswak, Neem active tooth paste

- *Strontium chloride*—Thermoseal, Sensodyne, Thermodont, Senolin, Stolin, Sensicure
- *Triclosan*—Thermokind-f, Sensicure, Pepsodent, Colgate, Senquel-f
- *Zinc sulfate*—Sensicure, Sensicure k, Sensodent-r

In-Office treatment (professional application in dental office)

- *Physical agents*—composites, resins, varnishes, sealants, soft tissue grafts, GIC (glass ionomer cement), and laser sealing off tubules.
- *Chemical agents*—corticosteroids, silver nitrate, zinc chloride, strontium chloride, formaldehyde, calcium hydroxide, potassium nitrate, potassium oxalate, fluorides, sodium citrate, sodium monofluorophosphate.

Mechanism of Action of Desensitizing Agents

Most of the therapies proposed till date for treatment rely on one of the two major suppressive mechanisms, i.e., sealing off the dentinal tubules or dampening neural impulses (potassium nitrate).

Sealing off or the reduction in the diameter of the tubule so as to limit the displacement/ flow of fluid in the dentinal tubules can be achieved by

- *Formation of smear layer*—it is produced by burnishing the exposed root surface. (orange woodstick or toothpick—partially occlude to dentinal tubule)
- *Formation of insoluble precipitates*—topical application will form insoluble precipitates within tubules. for example-
 - *Oxalate*—oxalate from potassium oxalate reacts with the ionized calcium in the dentinal tubule and forms insoluble calcium oxalate crystals. The crystals block the dentinal tubules and prevent fluid flow through the tubule.
 - *Silver nitrate*—silver nitrate precipitates protein constituents of odontoblastic processes, thereby partially blocking the dentinal tubules.
 - *Sodium fluoride*—sodium fluoride reacts with calcium and phosphate ions and forms calcium fluoride crystals thus blocking the dentinal tubule
 - *Stannous fluoride*—stannous fluoride forms dense layer of tin and fluoride containing tubular particles thus effectively blocking the dentinal tubules.
 - *Fluoride iontophoresis*—iontophoresis act by influencing ionic motion by electric currents which may enhance ion uptake by the dentinal tubules and aid in achieving desensitization. The process of influencing ionic motion by electric currents is known as electrophoresis, cataphoresis, or iontophoresis. The objective of fluoride iontophoresis is to drive fluoride ions more deeply into the dentinal tubule that cannot be achieved with topical application of fluoride alone.

- *Impregnation of tubules with resins*—sealing off the tubules with plastic resins: glass ionomer cement.
- *Sealing by dentin bonding agents*—sealing off the dentinal tubule by dentin bonding agents. They seal the dentinal tubules and thus prevent pain producing stimuli from reaching the pulp. Procedure is as follows:
 - Clean the sensitive dentin—each for 5 sec—wash and dry for 15-20 sec
 - A drop of enamel bond applied to dentin
 - Gluma—dentin bonding agent—5% glutaraldehyde primer and 35% hema (hydroxyl ethyl methacrylate).
 - Immediate and strong attachment to dentin
 - Prevent bacterial overgrowth in tooth/restoration interface—beneficial effect in inhibiting plaque accumulation on sensitive root surface
- *Surgical root coverage procedures*—various procedures are used to cover the denuded areas of teeth such as free gingival graft, connective tissue graft, laterally positioned flap, coronally positioned flap, subepithelial connective tissue graft and guided tissue regeneration.
- *Laser sealing off tubules*—helium-neon (HeNe) and Nd:YAG lasers are found to be effective in the treatment of dentinal hypersensitivity without detrimental pulpal effects. The lasers used for the treatment of dentin hypersensitivity can be divided in two groups.
 - *Low output power lasers*: helium-neon (HeNe) and gallium/aluminium/arsenide (Ga-Al-As) lasers.
 - *Middle output power lasers*- Nd: YAG (1064 nm) and CO₂ lasers (10,600 nm) at different wavelengths and exposure time are used to block the dentinal tubules effectively.
- Avoid using large amounts of dentifrice or reapplying additional dentifrice during brushing.
- Avoid hard bristled tooth brushes.
- Avoid over brushing with excessive pressure for prolonged periods of time.
- Avoid excessive flossing or incorrect use of other interproximal cleaning devices.
- Avoid picking at the gum or using tooth picks inappropriately.

Suggestions for Professionals

- Avoid over instrumentation of the root surfaces during calculus removal and scaling and root planing as it may cause
- Avoid over polishing the exposed roots during stain removal.
- Avoid violating the biologic width when placing crown margins causing subsequent recession.
- Avoid burning the gingival tissue during in-office tooth whitening or bleaching procedures.

Summary and Conclusion (Table 46-1)

Dentinal hypersensitivity is one of the most painful and least predictably treated chronic conditions in dentistry. In clinical practice, the professional approach to dentin hypersensitivity has been heavily treatment-based with little regard for control of the etiological agent and predisposing factors, which creates the problem. This is not surprising since the dentist and the sufferer are virtually bombarded with a vast array of products formulated to treat dentin hypersensitivity.

Patients treated for dentin hypersensitivity should be counseled about dietary acids and the importance of proper effective oral hygiene. Over-the-counter dentifrices will continue to have an important role in treating dentin hypersensitivity. Potassium nitrate, potassium oxalate, iontophoresis with 2% sodium fluoride is proven to be effective with varying degree of success in reducing the dentin hypersensitivity. In the future, dental lasers are expected to have an important role in treating hypersensitivity.

Instructions to be given to Patients while Prescribing Desensitizing Agent

- Hypersensitivity appears as a result of exposure of dentin, which is inevitable if calculus and plaque and their products are to be removed.
- Hypersensitivity slowly disappears over a few weeks.
- Plaque control is important for the reduction of hypersensitivity. Patient is instructed about proper tooth brushing technique as improper tooth brushing is one of the etiologic factors in dentin hypersensitivity.
- Desensitizing agents do not produce immediate relief. They must be used for several days to weeks (2-6 week) to produce results.

Prevention of Dentin Hypersensitivity

Suggestions for Patients

- Avoid gingival recession due to poor plaque removal by practicing good oral hygiene technique.

Mouthwashes (Table 46-2)

Mouthwashes are usually aqueous solutions in concentrated form of a substance with deodorant, antiseptic, local analgesic and astringent properties.

Mouthwashes comprise a large group of liquid compound used as oral rinse for cosmetic or therapeutic purpose.

Table 46-1: Desensitizing agents

Desensitizing agents	Trade name of toothpaste	Mechanism of action
Strontium chloride	Thermoseal Eanisam Desent Senolin Toss	Bicollodial binding and blocking of micro-tubular fibrillae on the exposed dentin. Strontium ions stimulate secondary dentin formation Modification of transmission of impulses and stimulation for re-calcification
Potassium nitrate	Senquel Sensodent K	Oxidizing effect or blocking of dentinal tubules
Formalin	Sensoform Dentoform	Protein precipitation
Strontium chloride and formaldehyde	Stolin	Same as strontium chloride and formalin
Potassium nitrate 5% sodium mono-fluorophosphates 0.7% available fluoride	Senquel-F	

Table 46-2: Mouthwashes

Drug	Trade name
0.2 % chlorhexidine gluconate	Clohex, hexidine, rexidin
0.12% chlorhexidine and 2% sodium benzoate	A.M-P.M.
1% Povidone iodine, essential oils	Betadine, alphasine, povidax, povidone
0.15% benzydamine hydrochloride	Tantum oral rinse
1.02% chloroxylenol and 0.12% menthol	Dettolin
Chamomilla extract in alcohol (42.8%), mentha oil (18.5 mg) anise oil (7 mg) and alcohol (0.1ml)	Kamillosan-N
Thymol (0.06%), eucalyptol (0.9%), benzoic acid (0.15%), menthol (0.04%)	Listerine

Indications for Antiplaque Mouthwash

- *Replacement for mechanical tooth brushing*—antiplaque mouthwash is used to replace mechanical tooth brushing when this is not possible acute oral mucosal and gingival infections, after periodontal or oral surgery, during the healing period, after cosmetic jaw surgery, in case of patient using intermaxillary fixation, and for mentally and physically handicapped patients.
- *Adjunct use*—as an adjunct to normal mechanical brushing in situations where this may be compromised by discomfort or inadequacies.
- After scaling when there is cervical hypersensitivity due to exposed root surfaces, prescribe mouthwashes for about 4 weeks. Measures to treat hypersensitivity should also be instituted simultaneously.
- Following subgingival scaling and root planning when the gingiva may be sore for a few days, use of a mouthwash is recommended for about 3 days.
- *Cleaning of mouth*—vigorous mouthwashing does help in keeping the mouth clean by moving the food debris, mucus and even bacteria.
- *Decrease bacterial population*—it is also used to decrease bacterial population, to provide topical anesthesia.
- *Reduction of oral acidity*—it also reduces oral acidity and inactivates odor producing salivary or bacterial enzymes.
- *Refresh the mouth*—the patient may use mouthwashes to debride the oral cavity after tooth brushing and to refresh the mouth or as an attempt to correct halitosis. From simple breath fresheners to products that can really influence oral health, a variety of mouthwashes are available in the market.
- *Resolution of chronic gingivitis*—Antiplaque or antimicrobial mouthwash is used to inhibit bacterial plaque formation and prevent or resolve chronic gingivitis. They can affect only supragingival plaque. So they have no role in the treatment of existing periodontal disease, since

they cannot either reach the subgingival environment or penetrate thick layers of established plaque. In these situations, they are used after supra- and subgingival scaling has been done, rendering the tooth surfaces clean, in order to maintain this situation for a short period when the soreness of the gingiva may prevent effective mechanical plaque control.

- *Indication for fluoride containing mouth rinse*—it is used to prevent dental decay. They may be recommended for children having orthodontic treatment, children with high caries risk, dry mouth and after radiation therapy.

Types of Antiplaque Mouthwashes

- *Mouthwashes containing essential oils*—essential oils derived by distillation from plants, have a characteristic odor and taste and should not be used in a concentration greater than 0.2%. The most commonly used essential oils are eucalyptus oil, methylsalicylates, orange oil, peppermint oil and spearmint oil. Listerine, one of the oldest mouthwashes available, is an essential oil/phenolic mouthwash. It has been shown to have moderate plaque inhibitory effect and some anti-gingivitis effect. Its lack of profound plaque inhibitory effect is because it has poor oral retention. Ethyl alcohol is used to enhance the solubility of organic compounds in water and should not exceed a concentration of 10% because of possible local irritation.
- *Phenol and its derivative*—they are also used for their antibacterial and anodyne effects in mouthwash preparations. Their value is limited by their toxicity, objectionable taste, sensitization properties, high cost and decreased activity in the presence of organic matter. Commonly used phenol derivatives are hexylresorcinol and thymol.
- *Mouthwash containing oxygenating agents*—oxygenating agents like Hydrogen peroxide, buffered Sodium peroxyborate and peroxy carbonate in mouthwashes have a beneficial effect on acute ulcerative gingivitis, probably by inhibiting anaerobic bacteria. Mechanism by which they inhibit anaerobic bacteria is that they release molecular oxygen which can destroy anaerobic bacteria.
- *Mouthwash containing bisguanide antiseptic*—bisguanide antiseptics, like Chlorhexidine, Alexidine and octenidine possess antiplaque activity. These are cationic agents with fungicidal activity and bactericidal action against gram positive and gram negative organisms. Bisguanide antiseptics are able to kill a wide range of micro-organisms by damaging the cell wall.
- *Mouthwash containing triclosan*—triclosan, a trichloro-2'-hydroxy diphenyl ether, is a non-ionic antiseptic. It has a moderate antiseptic effect when used as a mouthwash

in combination with zinc. It has been shown to reduce histamine induced dermal inflammation and reduces the severity and healing period of aphthous ulcers.

- *Colgate total plax mouthwash*—colgate Total Plax mouthwash has Triclosan and Sodium fluoride as its components. Triclosan has little or no substantivity, but its oral retention can be increased by its combination with copolymers of methoxy ethylene and maleic acid.
- *Povidone iodine*—povidone iodine appears to have no significant plaque inhibitory activity when used as 1% mouthwash and the absorption of significant levels of iodine through the oral mucosal may make this compound for prolonged use in the oral cavity. It could cause problem of iodine sensitivity in sensitized individuals. Piodin (Glaxo Wellcome), povidine Gargle (Stadmed) are povidone iodine mouthwashes available in the market.
- *Mouthwash containing sanguinarine*—it is a component of an alkaloid extract obtained from the dried rhizome of the bloodroot plant, sanguinaria Canadensis. Recently, it is incorporated with zinc chloride in dentifrices and in mouthwashes as an antiplaque and anti-gingivitis agent. The antibacterial activity is due to its ability to inhibit sulfhydryl dependent enzymes.

Alcohol Content of Mouthwashes

Most mouthwashes contain pharmaceutical grade alcohol, as a preservative and as a semi-active ingredient. Significant amounts of alcohol contained in many mouthwashes can lead to certain disadvantages. Care should be taken that they are not accidentally swallowed, especially by children, to avoid toxicity. Small children should not be advised mouthwashes, because they are not able to spit out properly. Moreover, most children have good gingival health.

Because of known links between alcohol consumption plus tobacco smoking and oral and pharyngeal cancer, it has been suggested that the frequent use of alcohol containing mouthwashes might increase the incidence of this form of cancer.

Lastly, alcohol containing mouthwashes have been shown to reduce the hardness of composite and hybrid resin restorations

Chlorhexidine Mouthwash

Chlorhexidine molecule gets adsorbed onto the oral surfaces and gets released at bactericidal level over prolonged periods. Due to this process, Chlorhexidine has antiplaque properties unsurpassed by other agents. The antibacterial action of Chlorhexidine is due to an increase in cellular membrane permeability followed by coagulation of the cytoplasmic macromolecules. It is effective *in vitro*

against Gram +ve and Gram -ve bacteria including aerobes and anaerobes and yeast and fungi.

The substantivity (the ability of drugs to adsorb onto and bind to soft and hard tissues) of Chlorhexidine was first described in the 1970s. Due to this property, Chlorhexidine can maintain effective concentration for prolonged periods of time. Different brands of Chlorhexidine are available in the market, e.g., Rexidin (Warren), Clohex (Group) and A.M.-P.M (Elder).

Structure

Chlorhexidine is a chlorophenyl bisguanide that has been used as an acetate and more commonly as a gluconate salt. It is N, N-bis (4-chlorophenyl)-3, 12-dimino-2, 4, 11, 13-tetra-azotetradecanedimidamide di-D-gluconate.

Mechanisms of Action

- *Absorption onto oral surface*—chlorhexidine molecule gets adsorbed onto the oral surfaces and is released at bactericidal levels over prolonged periods. Due to this process, chlorhexidine has antiplaque properties unsurpassed by other agents.
- *Antibacterial action*—this action of chlorhexidine is due to increase in cellular membrane permeability followed by coagulation of the cytoplasmic macromolecules. It is effective *in vitro* against gram +ve and gram -ve bacteria including aerobes and anaerobes and yeast and fungi. The positively charged chlorhexidine binds to negatively charged microbial cell surface. It is followed by disorganization of cytoplasmic membrane. Low concentration allows cytoplasmic constituent to leak out and high concentration coagulates them.
- *Blocking of acidic groups*—these groups on the salivary glycoprotein reduce the protein absorption to tooth surfaces.

- *Cell wall penetration*—in high concentration, chlorhexidine penetrates cell wall and causes precipitation of the cytoplasm.

Indications

- *Periodontal disease*—it is used in all forms of periodontal diseases.
- *Subgingival irrigation*—it is also used for sub-gingival irrigation of periodontal pockets.
- *Aphthous ulcer*—it also reduces the severity and duration of aphthous ulceration.
- *Substitution of mechanical plaque control*—where mechanical plaque control is not useful.
- *Denture stomatitis*—denture stomatitis has been treated by soaking dentures in 0.2% chlorhexidine overnight for 5 months combined with daily use of amphotericin B lozenges for 14 days.

Side Effects of Chlorhexidine

- *Unpleasant taste*—it has an unpleasant taste and it alters taste sensation. Interference with taste sensation is caused by denaturation of surface proteins on the taste buds.
- *Stains*—it produces brown stains on teeth, which is very difficult to remove. This can also affect the mucous membranes and tongue and may be related to the precipitation of chromogenic dietary factors onto the teeth and mucous membranes. Due to this reason, it is important to advise patients using chlorhexidine mouthwash to avoid the intake of tea, coffee and red wine during the duration of its use. Remember to severely restrict its use in patients with visible anterior composite and glass ionomer restorations since they also get stained.
- *Calculus formation*—chlorhexidine encourages supra-gingival calculus formation. It may be due to rise in pH

Table 46-3: Gum paints

Drugs	Trade name
2% zinc sulfate	Gingisol
Tannic acid (66.27%), glycerin, thymol (0.033%), potassium iodide (0.05%), menthol (0.05%) and iodine (0.03%)	Sensoform
Choline salicylate (8.7%), cetalkonium chloride (0.01%) and ethyl alcohol (39%)	Gelora
Choline salicylate (9%) and benzalkonium chloride (0.02%)	Zytee
Iodine (1gm), potassium iodide (2gm), alum (1.5gm), tannic acid (0.5gm), thymol (0.25mg), camphor (0.2mg) and menthol	Toss gum paint
Choline salicylate (8.7%), lignocaine hydrochloride (2%) and benzalkonium chloride solution (0.01%)	Dentogel Dologel
Tannic acid (2%), zinc chloride (1%) and cetrimide (0.1%)	Stolin

as a result of absorption of cationic agents and marked impact on bacterial integrity.

- *Soreness of oral mucosa*—desquamation and soreness of the oral mucosa can occur. It is due to precipitation of mucin layer, by reducing its lubricating effect.
- *Transient parotitis*—transient parotitis has also reported.
- *Altered taste sensation*—chlorhexidine mouthwash may alters taste sensation.

Gum Paints (Table 46-3)

Gum paint is just a stronger solution of a drug, which is used as mouthwash. They are used for topical application. They develop a strong concentration of the drug against inflamed tissue. They are combination of antiseptics and tanning agents. They are used for local application to the gums during severe bacterial infection and their inflammatory conditions. To apply it you have to dry the area and apply using cotton or index finger and it is not to be swallowed. When applied they provide a cooling, soothing, astringent effect and they have germicidal, fungicidal, anesthetics and healing properties. It is used in the treatment of stomatitis, inflamed/bleeding/spongy and painful gum conditions. It reduces sensitivity and increase gingival resistance against infection.

Introduction

Administration of drugs to pregnant patient is of significant concern. Two main concerns must be addressed when considering whether to give a drug to pregnant women. The first is that the drug may be teratogenic and the second is that drug can affect near term fetus.

One must always be aware of the teratogenic, toxic or otherwise harmful effects of the drug on the developing fetus. The physiologic changes during pregnancy and the consequent alteration in the pharmacokinetics lead to changes in drug absorption, distribution, metabolism and excretion.

As a general rule, it is best that no drug should be given during pregnancy, especially during the first trimester as it is period of organogenesis. Fortunately, most of drugs commonly used in dentistry are not contraindicated during pregnancy. Tetracycline and streptomycin are notably exceptions.

The fetus may metabolize a particular drug via a different pathway from that of mother or its metabolic product may bound more avidly in fetal thus leading to accumulation of drug or its metabolites in fetus. Also since body systems of fetus are not fully developed, the fetus cannot process medicine like mother's system so same drug can cause harm to fetus.

Pregnancy Trimesters

Pregnancy involves three trimesters each 3 months long.

- *First trimester*—in this trimester, different body organs in the fetus are forming. It is most critical time for teratogenicity. Dental prophylaxis with detailed instructions and a visual examination of the oral cavity without X-rays should be performed if the patient is pregnant. Elective dental treatment should be avoided

in the morning as women may feel nauseated in the morning.

- *Second trimester*—it is an excellent time for the patient to undergo dental prophylaxis if needed. The patient's periodontal status should be carefully evaluated during this period.
- *Third trimester*—the women begin to feel uncomfortable and it is difficult for her to lie in prone position for long period time. Drugs that may affect the newborn should not be given during this trimester. Positioning of patient on dental chair can cause hypotension due to compression of gravid uterus on the inferior vena cava, resulting in syncope. Stress can precipitate premature labor. Due to hormonal changes, gingival tissue shows exaggerated response to local irritants.

Pharmacokinetics in Pregnancy

- *Drug absorption*—high circulating levels of progesterone slow the gastric emptying as well as gut motility resulting in slower drug absorption. Parenteral drug administration is preferred in order to obtain a quick response. Drug compliance may be poor because of nausea and fear of adverse effect.
- *Drug metabolism*—hepatic drug metabolizing enzymes are induced during pregnancy probably by high concentration of circulating progesterone. This can lead to more rapid metabolic degradation especially of highly lipid soluble drugs. However, this is of little clinical consequence.
- *Drug excretion*—during pregnancy the renal plasma flow increases by 100% and glomerular filtration rate by 70%. Hence, drugs which depend for their elimination mainly on kidney are eliminated more rapidly than in non-pregnant stage, e.g. ampicillin, gentamicin and cephalosporin.

Recommended Drugs to be used in Pregnancy				
Type	Drugs	1st Trimester	2nd and 3rd Trimester	Comment
Local anesthetics	Lidocaine	Yes	Yes	First choice anesthetics, fetal bradycardia near term
	Mepivacaine	Yes	Yes	Fetal bradycardia near term
	Bupivacaine	No	No	Embryocidal in rabbits and high lipid solubility
	Benzocaine	Yes	Yes	Fetal bradycardia near term
Vasoconstrictors	Epinephrine	Yes	Yes	It can produce hypoxia (use cardiac dose)
Analgesics	Paracetamol	Yes	Yes	Teratogenic at over dose level
	Codeine	Limited dose	Limited dose	Respiratory distress near term high dose contraindicated
	Aspirin	No	No	Bleeding, prolonged parturition, premature closure of patent ductus arteriosus
	Ibuprofen	Yes (cautiously)	No	Same as aspirin
Antibiotics	Penicillin	Yes	Yes	Safe
	Erythromycin	Yes	Yes	Safe except estolate form
	Tetracycline	No	No	Stains teeth, affects bone
	Clindamycin	No	No	Only if alternative dose not exist
	Cephalosporin	Yes	Yes	Safe only if use as indicated
	Metronidazole	No	No	Carcinogenic and mutagenic in animals
Antifungal	Clotrimazole	No	Yes with caution	Poorly absorbed following topical or intravaginal application, abnormal liver function test in adults can occur.
	Ketoconazole	No	No	Embryotoxic in rat
	Nystatin	Yes	Yes	Safe
Sedative	Benzodiazepines	No	No	Cleft lip, neural tube defect
	N ₂ O with 50% O ₂	No	Possible with adequate O ₂	Ensure adequate oxygen intake, female operators avoid chronic exposure

Use of dental drugs by nursing mother			
Types	Drugs	Acceptable	Watch infant for symptoms of
Local anesthetics	Amides	Yes	Central nervous system changes
Vasoconstrictors	Epinephrine	Yes	Hyperactivity or irritability
Analgesics	Aspirin	Yes with caution	Avoid feeding for 1 hour after dose, occasional low dose pose no hazard, chronic high dose may pose problems
	NSAID	Yes with caution	Use ibuprofen (concentration in milk is low) avoid long acting NSAIDs
	Acetaminophen	Yes	Present in milk in small amount (peak 1-2 hours)
	Opioids	Yes	Small doses no problems and in larger doses sedation, poor feeding and constipation
Antibiotics	Penicillin	Yes	Allergic symptoms, diarrhea
	Erythromycin	Yes	Present in milk, diarrhea
	Cephalosporin	Yes	Allergic symptoms, diarrhea
	Tetracycline	No	Tooth staining
	Clindamycin	Yes/no	Diarrhea, pseudomembranous colitis
	Metronidazole	No	Carcinogenic in animal
Antifungal	Nystatin	Yes	Not absorbed into systemic circulation from mouth or gastrointestinal tract
	Clotrimazole	Yes	Excreted in milk, use nystatin first
	Ketoconazole	No	Express and discard milk
Antiviral	Acyclovir	Yes	Concentrated in milk
Antianxiety	Nitrous oxide	Yes	Excreted through mother's lung
	Benzodiazepines	No	Sedation, infants metabolize oxidized agent more slowly

- *Increase total blood volume*—there is increased total blood volume, because of increased fluid retention. This leads to change in cardiac output, blood pressure and glomerular filtration rate. This results in change in volume of distribution of drug, change in metabolism, change in absorption, change in excretion of drug, change in protein binding of drugs and passage of drug through placenta.
- *Teratogenicity*—it refers to capacity of a drug to cause fetal abnormalities when administered to pregnant mother. Drug can affect fetus at three stages, i.e. stage of fertilization and implantation, stage of organogenesis and stage of growth and development

Drugs	Abnormalities
Thalidomide	Phocomelia
Anticancer drug	Multiple defect, Fetal death
Tetracycline	Discolored and deformed tooth, Retarded bone growth.
Phenytoin	Craniofacial and limb defect, cleft lip, cleft palate
Phenobarbitone	Various malformations
Carbamazepine	CNS defect
Retinoids	Various abnormalities
Alcohol	Fetal alcohol embryopathy

Dental Management of Pregnant Patient

- *Elective treatment*—it can be postponed easily for the pregnant patient after parturition. However, emergency care should be taken into consideration. The best method of treatment is to eliminate source of pain. Thus for removal of caries, an infected pulp or tooth, surgical procedure should be done under small doses of local anesthetics to minimize use of systemic drugs. Dental procedures are best performed in 2nd trimester for benefit of fetus and optimal comfort of pregnant women.
- *1st trimester*—it is roughly 12–13 weeks. In this first 12 days from conception to implantation known as 'pre-implantation period', exposure to harmful drugs can kill the embryo. From the 13th day, there is period of organogenesis and so the fetus is susceptible to insult and injury resulting in malformation.
- *2nd and 3rd trimester*—after completion of organogenesis, there is considerable growth and development of existing structures like teeth, bones, CNS, endocrine, genitals and immune system. Malformation is less in II and III trimester but drug like streptomycin can still be harmful causing retardation of physical and mental growth,

premature labor or neonatal toxicity. The adverse effect of drugs on the fetus is dependant on the drug and the phase of pregnancy in which the drug is administered.

- *Preventive dental prophylaxis*—preventive dental prophylaxis should be undertaken at the beginning of the 2nd and 3rd trimester.
- *Radiographs*—radiographs are contraindicated in all but emergency situation, when taken lead shielding is mandatory.
- *Reduce chair time*—prolonged chair time must be avoided to prevent supine hypotension.
- *Position*—sitting up position is best for patient since low head position may cause pressure on vena cava and aorta in 2nd trimester
- *Fainting*—in case of fainting, place patient on left side with legs and head elevated. Oxygen and lime juice with glucose could be given and vital sign monitored.
- *Serious complication*—more serious complication such as seizures and active vaginal bleeding or severe cramping require emergency care in hospital.

Guidelines for Prescribed Drugs in Pregnancy

- *Don't use drug unless it is absolute necessary*—use drug in pregnant patient only when it is absolutely necessary.
- *Ruling out possibility of pregnancy*—rule out possibility of pregnancy in every female of reproductive age group and restrict drug usage.
- *Risk and benefit ratio*—prioritize drug usage in the situation and avoid drug usage if the non-usage can do i.e. risk Vs benefit ratio should be calculated.
- *Lower doses*—use lower than usual doses of drug if necessary for short term.

Consideration in Lactation

Almost all drugs are excreted into the breast milk to some extent. An infant normally ingests approximately 1% of the total material dose of a drug. Dental practitioner must remember that drugs should be selected which have short half-life, sustained release formulation should be avoided, drugs should be taken immediately after nursing.

Emergency Drugs used in Dentistry

5

Introduction

Though rare, life-threatening medical emergencies can and do occur in the dental environment whose incidence is largely unknown. All health care providers, dentists must be prepared to recognize and properly manage patients of medical emergencies in the dental office.

In all cases of emergencies, the best and foremost method of managing medical emergencies is by preventing them from occurring. With this in mind, it is essential to take a comprehensive medical history from any patient who is about to receive dental care.

The following section reviews the more common emergency drugs that the dental team may have to administer in general dental practice.

Emergency Management

First and foremost in emergency management is the ability to effectively provide basic life support, or BLS (includes cardio-pulmonary resuscitation), when appropriate. It is recommended that all dental health care professionals receive regular training in BLS for health care providers, because these skills are maintained only through repetition.

For certain individuals, like those who practice in the remote areas where medical services (routine or emergency) are not readily available, additional training in advanced cardiac life support, pediatric advanced life support, or both may be warranted. Didactic and hands-on training in the prevention, recognition and management of common emergencies also is recommended. Examples of common emergencies include seizures, cardiovascular and respiratory distress, altered consciousness, chest pain and drug related emergencies.

Advanced cardiac life support training involves the following:

- Adjuncts for airway control and ventilation (including intubation)
- Patient monitoring and dysrhythmia recognition.
- Defibrillation and synchronized cardioversion.
- Cardiovascular pharmacology.
- Acid-base balance maintenance.
- Venipuncture.
- Resuscitation of infants, including the newborn.

In addition, all dental offices should maintain at least the basic recommended emergency equipment and drugs. The content and design of these kits should be based upon each practitioner's training and individual requirements. Proprietary emergency drug kits are available, but none of these kits is compatible with the needs of all practitioners. It does recommend that dentists, after considering their specific training and special needs, design their own individualized emergency kits if proprietary kits do not meet their needs.

Types of Emergency Drugs

Drugs that should be promptly available to the dentist can be divided into two categories.

- *Essential emergency drugs*—the first category represents those which may be considered essential. (oxygen, epinephrine, nitroglycerine, salbutamol, antihistamines, aspirin).
- *Additional emergency drugs*—the second category contains drugs which are also very helpful and should be considered as part of the emergency kit. These supplementary drugs. (glucagon, ephedrine, atropine, corticosteroids, morphine/nitrous oxide, nalaxone, lorazepam, midazolam, flumazenil).

Emergency Drug Kit

The dental office emergency kit should be as simple as possible. The emergency drug kit describes in the following

section is a simple organised collection drugs and equipments that has been found to be highly effective in managing those life-threatening situations requiring the administration of drugs. However in most emergency situations, drugs are not necessary for the proper management of the patients. First and foremost in the management of these situations will be the steps of basic life support. In the light of the confusion it seems clear that there is an urgent need to try to rationalise the content of the emergency drugs box and to provide clear, standardised guidance on which emergency drugs they should stock and be able to use.

The following section reviews the more common emergency drugs that the dental team may have to administer in general dental practice.

Adrenaline

- **Indication**—it is the drug of choice for the management of the acute allergic reactions especially in the respiratory and cardiovascular manifestations of allergic reaction.
- **Anaphylactic shock**—an allergic (type 1 hypersensitivity) reaction may be precipitated by any material or drug to which the patient has been sensitized. Life-threatening events include cardiovascular collapse (90%), bronchospasm (30%), angioedema (25%), and pulmonary edema (49%). Severity varies, and onset of anaphylaxis may be delayed for up to 6 hours or be biphasic, reoccurring in 5% of patients after clinical recovery. In addition to adrenaline, high flow oxygen should be administered to all patients in anaphylactic shock. Second-line drugs, used to prevent relapse, are chlorpheniramine and hydrocortisone.
- **Acute asthmatic attack**—adrenaline is also used in acute asthmatic attacks.
- **Cardiac arrest**—adrenaline is used highly advanced cardiac life support protocols.
- **Mode of Action**
 - **Contraction of vascular smooth muscle**—adrenaline is a sympathomimetic amine that activates both alpha and beta adrenoceptors. Contraction of vascular smooth muscle (alpha-mediated). An increased blood pressure helps to maintain cerebral and coronary perfusion.
 - **Increase cardiac output**—increased force and rate of cardiac contraction (Beta1-mediated). This action increases cardiac output, which helps to maintain the blood pressure. However, this may be damaging as it increases myocardial oxygen requirements and may precipitate ischemia.
 - **Relaxation of bronchial muscle**—relaxation of bronchial smooth muscle (Beta2-mediated). Increasing the caliber of the airway in acute anaphylaxis helps to

re-establish airflow restricted by bronchospasm and edema.

- **Inhibition of histamine release**—inhibition of histamine release by mast cells (Beta2-effect). Histamine is an important early mediator, responsible for some of the hemodynamic changes encountered in anaphylactic reactions.
- **Undesirable action**—undesirable action includes its tendency to predispose the heart to dysrhythmia and its relatively short duration of action.
- **Administration**—adrenaline may be given intramuscularly, subcutaneously or intravenously.
- **Dose**—adrenaline is available in two concentrations: 1:1000 (reserved for intramuscular and subcutaneous use) and 1:10 000 (for intravenous administration). It is available in ampoules or pre filled. The following table outlines the recommended volume of 1:1000 adrenaline that should be administered according to age during anaphylactic reactions.

Age	Volume of 1:1000 adrenaline (ml)	Dose (µg)
2	0.2	200
3-4	0.3	300
5	0.4	400
6-12	0.5	500
Adult	0.5-1.0	500-1000

- **Side effects, contraindication and precaution**—supraventricular and ventricular tachydysrhythmia may develop. Should be used with caution in pregnant women because it may decrease placental blood flow and may induce premature labor.

Chlorpheniramine

- **Action**—it is an antihistaminic drug alternative drug is diphenhydramine. Antihistamines are useful in the treatment of the delayed allergic response and in the definitive management of acute allergic reaction. Antihistamines act as a competitive antagonist of histamine. They do not prevent the release of histamine from the cell in response to injury, drugs, or antigens but do prevent access of histamine to its receptor site in the cell and thereby block the response of the effectors cell to the histamine. They are also the potent local anesthetics, diphenhydramine and triphelennamine being particularly potent in this regard. Potential side effect of most antihistamines is a degree of cortical depression which causes sedation. Therefore, Chlorpheniramine is preferred over diphenhydramine as it has less sedative effect.

- *Indication*—delayed allergy, definitive management of acute allergy, as local anesthesia in patients having history of allergy to local anesthetics.
- *Side effects, contraindication, precaution*—side effects include central nervous system depression, decreased blood pressure, it causes thickening of bronchial secretions therefore contraindicated in management of acute asthmatic attacks.
- *Dose*—the drug may be given orally, intramuscularly, subcutaneously or intravenously. For the management of allergic reactions localized to the skin, a dose of 4 mg in adults may be administered orally every 4 to 6 hrly, to a maximum of 24 mg/day.

Oxygen

- *Indications*—it is the most important drug in the entire emergency kit. Oxygen is indicated in all medical emergencies except hyperventilation. Oxygenation prevents hypoxia that may be damaging to vital organs such as the brain and heart.
- *Administration*—ensuring Airway Patency before oxygen is delivered, it is essential to ensure that the airway is patent. Foreign bodies, blood, vomit, and soft tissues may occlude the air space. The airway may be re-established by using the head tilt and chin lift or jaw thrust techniques. Airway adjuncts such as oropharyngeal (Guedel) airways may be used in the unconscious patient to hold the tongue in an anterior position away from the posterior pharyngeal wall. These airways are contraindicated in conscious or semiconscious patients where protective reflexes are active.
- *Oxygenation*—if the patient is breathing spontaneously, a facemask with an attached oxygen supply, running at a flow rate between 4 and 6 /min, may be used to deliver oxygen and help prevent hypoxia. Positive pressure ventilatory support may be provided in respiratory arrest.
- *Dose*—during cardiorespiratory arrest, the chest compression to ventilation ratio for adults 15:2 if one resuscitator is present and 5:1 if two are present.

Nitrates and Nitrites (Glyceryl Trinitrate or Nitroglycerine and Amyl nitrite)

- *Indication*—nitroglycerine and amyl nitrite was the first member of this group to be used as coronary vasodilators more than 100 years ago. These vasodilators primarily used in immediate management of chest pain usually caused by angina or myocardial infarction. Glyceryl trinitrate (GTN) is used for the prophylaxis and relief of angina. Angina, defined as discomfort due to myocardial

ischemia, occurs whenever there is an imbalance between myocardial oxygen supply and demand. Atherosclerotic narrowing of the coronary lumen results in insufficient oxygenated blood being delivered to the myocardium during periods of increased activity.

- *Mode of action*—the principle site of action of GTN is smooth muscle. Within the smooth muscle cell, GTN is converted to nitric oxide which activates the enzyme soluble guanylate cyclase (SGC). Activation of SGC results in increased cyclic guanosine monophosphate (cGMP) production, which leads to relaxation of the smooth muscle cell. As the vascular smooth muscle is relaxed and resting blood pressure is lowered, myocardial oxygen requirement is reduced leads to the relief of angina. GTN improves the myocardial oxygen supply: demand ratio by reducing cardiac workload and increasing the blood supply to the myocardium.
- *Side effect, contraindication and precaution*—the chief disturbances occur due to sudden hypotension. Headaches, postural hypotension, and flushing of face, tachycardia, thready pulse and fainting and complete nitrate syncope might occur. Tolerance is developed rapidly. Methemoglobinemia because of its mild hypotensive action, nitroglycerine is contraindicated in hypotensive patients. Because nitroglycerine is an unstable drug in tablet form, it must be replaced, usually within 3 weeks of its initial use.
- *Administration*—Sublingual tablets (300 micrograms). Uptake is delayed because of the initial time taken for the tablet to dissolve. Spray (400 micrograms metered dose). This is preferable to tablets as the solution is rapidly absorbed, no special storage is required.
- *Dose*—if a patient known to suffer from angina experiences chest pain, they should be placed upright to facilitate respiratory movements. In adults, a dose of 0.3 to 1 mg should produce symptomatic relief within 3 minutes. The effective duration of action is only 20 or 30 minutes; thus, dosing may have to be repeated. Oxygen should also be administered to all patients experiencing acute chest pain. If symptoms are not relieved within 10 minutes, myocardial infarction should be suspected.

Nitrous Oxide

- *Indications*—nitrous oxide may be used for its analgesic properties in the initial management of myocardial infarction (MI). The pain experienced during an MI is often more severe and of longer duration than that in angina. It may lead to further deterioration of cardiac function as it increases sympathetic output, which will elevate the oxygen demands of an already starved myocardium.

- *Mode of action*—many theories of the mechanism of action of general anesthetic agents such as nitrous oxide have been proposed. It is thought that these agents alter, either directly or indirectly, the function of the membrane proteins involved in the conduction of nervous impulses.
- *Administration and dose*—a combination of 50% nitrous oxide and 50% oxygen is used to produce analgesia without loss of consciousness.

Anticonvulsant (Diazepam, Midazolam)

- *Indication*—convulsion may occur in the dental office under several circumstances like overdose or toxicity to the local anesthetics, epileptic seizures, and febrile convulsions. Therefore anticonvulsant drug should be kept in the emergency kit. Seizure disorder is characterized by a stimulation of the central nervous and cardiopulmonary and cardiovascular system, followed by a period of depression of these same systems. as the degree of post-seizure depression is accentuated and its duration is prolonged because of the pharmacological action of the barbiturate. The benzodiazepines, unlike barbiturates, will usually terminate seizure activity without the pronounced depression of the respiratory and cardiovascular system. It is also used in termination of prolonged seizures caused by status epilepticus, local anesthetic toxicity, in hyperventilation and in thyroid storm for sedation.
- *Side effect, contraindication and precaution*—the major side effect of benzodiazepines is respiratory depression and arrest; however, with proper titration during administration, this is unlikely to occur.
- *Dose*—midazolam in 5 mg/ml in 1, 2, 5, and 10 ml vials, diazepam 5 mg/ml in 2 ml ampules.

Methoxamine/Phenylephrine

- *Action*—this one more vasopressor drug is included in the emergency drugs kit because of various shortcomings of adrenaline. Adrenaline is primarily used in the management of the acute allergic reactions and in cases of clinically mild to moderate hypotension. In addition to an increase in blood pressure, adrenaline cause an increase in workload of the heart through its effect on heart rate and cardiac contraction; it also increases the irritability of the myocardium by sensitizing it to dysrhythmias. For this reason, it seems desirable to utilize a vasopressor that will produce to utilize a vasopressor which produce a moderate increase in blood pressure without unduly stimulating the myocardium. Methoxamine and phenylephrine elevates blood pressure through peripheral vasoconstriction.
- *Indication*—in management of hypotension, in which the status of heart is unknown and the intent is to raise the

blood pressure without cardiac stimulation. Possible uses are in syncopal reaction, drug overdose reaction, postseizure states, acute adrenal insufficiency and allergy.

- *Side effect, contraindication, precaution*—vasopressors are contraindicated in patients with high blood pressure or ventricular tachycardia, and such drugs are to be used with extreme caution in patients with hyperthyroidism, bradycardia, partial heart block, myocardial disease, or severe atherosclerosis.
- *Availability*—methoxamine 10 mg/ml or phenylephrine 10 mg/ml.

Antihypoglycemic (50% Dextrose or Glucagon)

Glucagon

- *Indication*—glucagon is a pancreatic hormone that stimulates hepatic glycogenolysis and gluconeogenesis. Glucagon may be given to the unconscious hypoglycemic patient when intravenous access cannot be secured for the administration of glucose. In conscious patients, a sweet drink is sufficient to elevate plasma glucose levels. Oral glucose must not be given to unconscious patients because of the risk of pulmonary aspiration. Hypoglycemia, defined as a blood glucose concentration of less than 2.5 mmol/l, most commonly occurs in insulin-dependent diabetes. Hypoglycemia may result if a patient takes an insulin overdose, patient takes the correct dose but with no food or patient exercises or undergoes a stressful situation.
- *Mode of action*—glucagon increases plasma glucose by stimulating glycogenolysis and gluconeogenesis in the liver. An additional action is inhibition of glycogen synthesis and glucose oxidation. In adipose and hepatic tissues, glucagon causes lipolysis, resulting in the production of fatty acids which further increase gluconeogenesis.
- *Administration and dose*—in adults, 1 mg (0.5 mg in children up to 12 years) may be given intramuscularly into the deltoid or gluteal areas.

Glucose/Dextrose 50%

- *Indications*—glucose may be administered to the conscious or unconscious hypoglycemic patient.
- *Administration*—glucose may be given orally or intravenously. Intravenous administration is the most rapid and effective method of elevating plasma glucose levels.

Salbutamol /Albuterol /Metaproterenol

- *Indication*—asthmatic patients and patients with allergic reactions manifested primarily by respiratory difficulty

will require the use of bronchodilator drugs. These are β_2 adrenergic agonists have specific bronchial smooth muscle relaxing properties with little or no stimulatory effect on cardiovascular or gastrointestinal system. Salbutamol, a potent bronchodilator, is used in the management of acute asthma. Allergic reactions with bronchospasm.

- *Mode of action*—salbutamol is a selective Beta2-agonist which relaxes bronchial smooth muscle.
- *Administration*—to minimize the chance of adverse effects and to produce the most rapid onset of action, salbutamol is administered by inhalation (nebulizer)

Hydrocortisone/Dexamethasone

- *Action*—hydrocortisone, an endogenous adrenal hormone, possesses predominantly glucocorticoids activity and is essential for human survival. Administration of steroids for therapeutic purposes has a negative feedback effect on the hypothalamus and anterior pituitary gland, which eventually leads to atrophy of the adrenal cortex and resultant inability to secrete hydrocortisone in response to stress (acute adrenal insufficiency). Under these circumstances, a patient may collapse due to hypoglycemia and hypotension if a stressful situation, such as dental treatment, is encountered.
- *Indication*—therefore, exogenous hydrocortisone should be administered preoperatively to susceptible patients to restore the normal physiological response to stress. If acute adrenal insufficiency does occur, prompt administration of hydrocortisone and immediate hospitalization is recommended (Dexamethasone and methylprednisolone are contraindicated in acute adrenal insufficiency). Corticosteroids will be administered in the management of an acute allergic reaction, after the acute phase has been brought under control. The primary value of the corticosteroid is in the prevention of recurrent episodes of anaphylaxis.
- *Administration and dose*—hydrocortisone may be administered by the oral, intramuscular or intravenous routes. The dose varies according to the age and situation (25 to 200 mg).
- *Side effect, contraindication, precaution*—except in life threatening emergencies steroid is contraindicated in presence of pre-existing infection, peptic ulcer, and diabetes mellitus.

Atropine

- *Action*—it is a parasympathetic blocking agent, it is recommended for the management of symptomatic bradycardia. By enhancing discharge from the sinoatrial

node, atropine may provoke tachycardia. Atropine will be of benefit in situations in which the patient has an overload of parasympathetic activity on the heart. Extremely fearful patients are likely candidates for this purpose. When stimulated, the vagus nerve acts to decrease SA node activity, thereby slowing the heart rate, when the heart rate become overly slow, cerebral blood flow is decreased and clonical signs and symptoms of cerebral ischemia are noted. By blocking this effect atropine acts to maintain adequate cardiac output and cerebral circulation.

- *Indication*—bradycardia and hemodynamically significant bradydysrhythmia.
- *Side effect, contraindication and precaution*—large dose of atropine may produce clinical signs of overdose, including hot dry skin, headache; blurred nearsightedness; dry mouth and throat; disorientation and hallucinations; atropine is contraindicated in glaucoma or prostrate hypertrophy.
- *Dose*—atropine available in 0.5 mg/ml in 1 ml vial.

Respiratory Stimulant Aromatic Ammonia

- *Action*—aromatic ammonia is a strong respiratory stimulant. It is available in silver gray vaporole, which is crushed and placed under the breathing victim's nose until respiratory stimulation is affected. Aromatic ammonia has a noxious odour and irritates the mucous membrane of the upper respiratory tract, stimulate the respiratory and vasomotor center of the medulla. This action is in turn increases respiration and blood pressure
- *Indication*—vasodepressor syncope, respiratory depression not induced by opioid analgesics.
- *Side effect, contraindication and precaution*—used with caution in patients with chronic obstructive pulmonary disease or asthma. Its irritating effects on the mucous membrane of the upper respiratory tract may precipitate bronchospasm.
- *Dose*—silver gray vaporole containing 0.3 ml of aromatic ammonia.

Drugs for Advanced Cardiovascular Life Support

These drugs should be included only by those doctors who have completed the course in advanced cardiovascular life support. Essential ACLS drugs include epinephrine, oxygen, lidocaine, atropine, dopamine, morphine sulphate and verapamil.

Most of the drugs are already discussed.

Lidocaine

- *Indication*—lidocaine (xylocaine) is considered the primary antidysrhythmic drug in ACLS. It is used

extensively in the management of cardiac dysrhythmias, especially those of ventricular origin that develop after acute myocardial infarction. Lidocaine used in premature ventricular contractions occurring more than six times per minute, sustained ventricular tachycardia and in ventricular fibrillation that is refractory to electrical defibrillation.

- *Side effects*—excessive dose of lidocaine produce myocardial, circulatory, and CNS depression

Dopamine/Dobutamine

- *Action*—dopamine is a chemical precursor of norepinephrine. In large doses it stimulates both α and β adrenergic receptors at lower dose it dilates renal, mesenteric, and cerebral arteries. Dopamine also stimulates the release of norepinephrine; it is indicated for administration in hemodynamically significant hypotension in the absence of hypovolemia. Dobutamine is synthetic sympathomimetic amine that exerts significant inotropic effects by stimulating β_1 and α adrenergic receptors in the myocardium. Its β stimulating action generally overweighs its α stimulating action, usually results in a mild vasodilatation.
- *Indication*—the primary therapeutic indication for dopamine is to treat hemodynamically significant hypotension in the absence of hypovolemia.
- *Side effect*—dopamine may induce or exacerbate supraventricular or ventricular dysrhythmia. It also may imbalance the supply and demand of O_2 to myocardium, inducing or exacerbating myocardial ischemia. Nausea and vomiting frequently are noted with dopamine administration. It is available in 200 mg, 400 mg, 800 mg in 5 ml ampoules.

Morphine Sulphate/Meperidine

- *Indication*—analgesics are used in emergency situations in which acute pain or anxiety is present. Pain or anxiety increases the myocardial workload which increases the O_2 requirement of the myocardium which may worsen the condition. Two such circumstances include acute myocardial infarction and congestive cardiac failure. It is used in acute myocardial infarction, congestive cardiac failure, intense, prolonged pain or anxiety.
- *Side effect*—opioid agonists are potent central nervous and respiratory system depressants. Monitoring of the vital signs is mandatory whenever these drugs are used. Use of opioid agonists are contraindicated in victims of injury and multiple trauma: and should be used with caution in patients with compromised respiratory function.
- *Dose*—morphine is available as 8, 10, and 15 mg/ml and meperidine comes in 50 and 100 mg/ml doses.

Verapamil

- *Action*—it is a calcium channel blocker drug. Verapamil is extremely effective in management of supraventricular tachycardia. It slows conduction through the atrioventricular node, reducing ventricular response to atrial flutter and fibrillation.
- *Indication*—in emergency cardiac care verapamil is primarily used in treatment of paroxysmal supraventricular tachycardia.
- *Side effect and contraindication*—a transient decrease in arterial pressure may be noted because of peripheral vasodilatation. Verapamil is not recommended in ventricular tachycardia; it may induce severe hypotension and predispose the patient to ventricular fibrillation. It is available for injection as 2.5 mg/ml in 2 ml and 4 ml ampoules.

Antidotal Drugs

In order to manage the emergency situations like overdose or toxicity reactions caused by various drugs used primarily for sedation or general anesthesia four categories of antidotal drugs are used it includes the following;

- Opioid antagonists, e.g. Naloxone or nalbuphine.
- Benzodiazepine antagonist, e.g. Flumazenil.
- Antiemergence delirium drug, e.g. Physostigmine,
- Vasodilator, e.g. Procaine.

Naloxone/Nalbuphine

- *Action and indication*—the most significant side effect of opioid agonist is their ability to produce respiratory depression by diminishing the responsiveness of the brain's respiratory center to the arterial carbon dioxide. Naloxone is the only opioid antagonist free of any agonistic properties. It also reverses the other properties of the opioid-like analgesia and sedation. Naloxone may be administered endotracheally in situations where IV access is not available. Improved respiratory function is noted within 2 minutes. Nalbuphine, having opioid agonist-antagonist properties, is used successfully to reverse respiratory depression induced by opioid agonists. And because of its own analgesia-inducing properties it does not entirely remove postsurgical analgesia or sedation.
- *Side effect and contraindication*—naloxone's effect lasts only 30 minutes, respiratory depression may recur if previously given opioid is of long duration. The IM administration of second dose of the naloxone is recommended, its onset is slower but for longer duration than that of IV dose. This minimizes the recurrence of respiratory depression. Naloxone must be administered with extreme care to persons with known or suspected

physical dependence on opioid. Naloxone's complete reversal of agonist effect of opioid may produce severe withdrawal symptoms.

- **Dose**—it is available in 0.4 mg/ml in 1 ml ampoule or 10 ml vial for adults and 0.2 mg/ml in 2 ml ampoules for pediatric administration.

Flumazenil

- **Action**—benzodiazepines are supposed to be most safe drug for anxiety control and sedation. Some side effects like emergence delirium, excessive duration of sedation, and possibly significant respiratory depression do occur. Presence of antagonist for benzodiazepines adds safety to the IV sedation. Flumazenil produce rapid reversal of sedation and to improve the patient's ability to comprehend and obey commands. The duration of antrograde amnesia associate with midazolam was also reduced with use of flumazenil. Flumazenil also decrease the recovery time from midazolam sedation, increase alertness, and provide decrease amnesic effect in geriatric patients. Reversal with flumazenil is not effective following the oral administration of benzodiazepines.
- **Indication**—it is used for reversal of clinical action of parenterally administered benzodiazepines.
- **Side effect**—flumazenil may produce rebound anxiety state in some patients.

Physostigmine

- **Action**—several drugs that are primarily used to induce sedation have the ability to produce emergence delirium also called as anticholinergic syndrome. In this phenomenon the patient appears to lose contact with reality. There may be increase muscular movement, and patient makes unintelligible sounds. Physostigmine a reversible cholinesterase with the ability to cross the blood-brain barrier has become a drug of choice in the management of emergence delirium.
- **Indication**—for reversal of emergence delirium.
- **Side effect, contraindication and precaution**—side effects include increase salivation, possible emesis, and involuntary urination and defecation. If administered rapidly physostigmine can produce bradycardia and hypersalivation. Atropine should always available whenever physostigmine is administered because it is antidote to physostigmine. Physostigmine should not be given in patients with asthma, diabetes, cardiovascular disease, or mechanical obstruction of gastrointestinal or genitourinary tract.

Procaine

- **Action**—whenever there is IM or IV administration of the drug is present, a local anesthetic with significant

vasodilating property is recommended in the emergency kit. Indications for the administration of the procaine are extravascular injection of an irritating chemicals and intra-arterial administration of the drugs. In both cases there is problem of localized tissue irritation and compromised circulation in a local area. Procaine possesses excellent vasodilating properties along with its anesthetic actions, which make it an ideal drug in these situations.

- **Indication**—management of vasospasm and compromised circulation following intra-arterial injection of the drug. And in Management of extravascular injection of irritating drugs or chemicals.
- **Side effect**—allergy to the ester type local anesthetics is not uncommon. Sensitivity test is recommended before administration.

Emergency Equipment

Along with the emergency drugs the emergency equipments are equally important. Personnel who are expected to use these equipments must be well trained in its proper use.

- IV set/cannula/scalp vein set
- Oxygen cylinder
- O₂ delivery system
- AMBU bag
- Syringe and needles
- Tourniquets
- Macgill's forceps
- Suction and suction tips
- Oropharyngeal airways
- Endotracheal tubes
- Laryngoscope

Maintenance of Emergency Kit

- **Freely available**—it should be freely available.
- **Constant place**—the place for keeping the emergency kit should be constant and should not be changed.
- **Sign board**—location of the kit should be highlighted by the placard or sign board.
- **Orientation of working staff**—all the working staff should be oriented towards it.
- **Periodic checking**—it should be periodically checked for the working condition of the equipments, shortfall in the drugs, expiry date of the drugs, and prompt rectification should be made.
- **List of drug**—a list of contents of emergency drug kit drugs along with their expiry date, should be paste on the cover of the kit for the convenience of periodic inspection.
- **Replacement of drugs after used**—whenever the drugs are used they should be immediately replaced.

Emergency kit for dental office					
Group	Drug	Use	Concentration	Dose	Route
Anti-allergy	Epinephrine	Anaphylaxis Acute asthma	1:1000	0.3 mg	Subcutaneously
Opioid antagonist	Naloxone	Opioid overdose	0.4 mg/ml	0.4-2 mg	IV or Subcutaneously
Antihistamine	Benadryl	Allergic reaction	10 mg/ml	50 mg	IM, IV
Anticonvulsant	Diazepam	Prolonged seizure	_____	5-10 mg	IM, IV
Oxygen	Oxygen	Respiratory distress	100% inhalation	_____	_____
Vasodilator	Nitroglycerine	Acute angina pectoris	0.4 mg/spray	0.4 mg	Sublingually
Stimulant	Aromatic ammonia	Syncope	Inhalant	0.3 ml	Inhalation
Anti-hypoglycemic agent	Glucose	Hypoglycemia	Few teaspoonfuls	_____	Orally
Analgesic	Morphine	Myocardial infarct	10 mg/ml	10 mg	Orally

Professional Hazards of Dentistry

Introduction

Medical faculty ensures service to humanity, personal job satisfaction and fulfilment of professional requirements but, it also has certain shortcomings and discrepancies. Dentistry, being an important branch of medical sciences is no exception to this.

Classification

- Professional hazards to dentist from the patients.
- Hazards to the dentist from his working conditions, methodology of practice and materials used.
- Hazards to the dentist from law, i.e. 'consumer protection act (CPA)'.

Professional Hazards to the Dentist from the Patients

Dentistry has an environment, which is at least, dangerous and at worst, lethal. Most often patients suffer from one or the other diseases and due to mass awareness of the importance of these diseases, the problems arise. They are further aggravated by the fact that our profession deals with patient's saliva, blood and mucus which have potential pathogenic microorganisms and are on a constant look out for a portal of entry.

Hepatitis B and AIDS are the most threatening and contagious in almost all cases of infections can be transmitted percutaneously or nonpercutaneously and as dental treatment involves use of small sharp instruments; opportunity always exists for inadvertent percutaneous wounds to operator or the dental staff and thus inevitable spread of infection.

Other infectious microorganisms like viruses, bacteria and fungi can also be transmitted in the dental office and

may either cause a relatively innocuous infection (common cold) or lead to temporary or even long-term debilitation or even death.

Viruses are often shed asymptotically in saliva or other secretions and cause infection to dentist, i.e. herpes simplex virus infecting eyes, hands, fingers. Health care providers can also be a victim of measles, chickenpox, infectious mononucleosis, cytomegalovirus infection, herpes zoster or mumps.

Possibly, dentist gain an infection from patient in contagious stage of syphilis or tuberculous carrier, which is definitely a matter of concern.

Preventive Approach

General

- *Proper medical history*—medical history should be taken thoroughly and should be upto date.
- *Cleaning instrument*—clean the instruments before sterilization, to remove all visible foreign deposits.
- *Sterilization methods*—sterilization methods should be effective against all known pathogens and/or use of autoclave for various instruments. Working surfaces and dental units should be cleaned with chemical disinfectants such as 70% isopropyl alcohol, sodium hypochlorite solution and/or glutaraldehyde.
- *Disposable items*—disposables items like suction tips, impression trays, beakers, needles, towels, masks, and caps should be used.
- *Aspiration and ventilation*—use of high speed aspirators which exhaust externally and proper ventilation will definitely reduce the risk of cross-infection from the aerosols that are formed during certain dental procedures.
- *Management of sharp items*—sharp items like needles, scalpels and local anesthetic cartridges should be placed in a soft container. Collection and incineration of surgical waste should be arranged.

- **Training**—all dental staff should understand the policies for prevention of cross-infection and implement them. Review all the procedures from time to time to ensure that they are being carried out correctly.

Personal protection

- **Gloving**—use of operating gloves and washing hands in between patients with appropriate chemicals are some of the important protective measure.
- **Dental dam**—uses of dental dam provide an excellent barrier from microbial contamination from primary source, i.e. the patient's mouth.
- **Management of cuts and wounds**—cuts and wounds should be covered with waterproof dressings, at all times, even if gloves are worn.
- **Vaccinations**—boosting immune defense of the operator by appropriate vaccinations is compulsory.
- **Face masks and protective eyeglasses**—well fitting face masks and protective eyeglasses should be used during high speed cavity preparations or while using ultrasonic scalers and undertaking surgical procedures.

Professional Hazards to the Dentist from his Working Conditions, Methodology of Practice and Materials Used

Psychological Stress and Fatigue

- **Causes**—psychological climate in a dentist's office is as equally important as is technical expertise. Dentistry has a reputation of being a stressful occupation. Worrying about how others expect you to act, counteracting depression, pressure of keeping time schedules, dealing with anxious and uncooperative patient, law suit threat are all common sources of stress.
- **Burnout syndrome**—we all appear to be prime candidates for the 'burnout syndrome' a syndrome of emotional exhaustion and cynicism frequently seen amongst professionals involved in direct communication with patients.
- **Prevention**—you should cope up with and/or resolve the origin of cause and develop a pattern of healthy living.

Musculoskeletal Complaints

- **Causes**—we all are guilty of adopting bizarre positions while treating our patients and even though such technique cause minimal patient discomfort, we as dentist, are in turn rewarded with muscle fatigue, lower back aches, shoulder problems, etc.
- **Prevention**—reduction of physical stress to the body by adopting a correct posture is important in everyday practice. Low seated, closely supported dentistry with

certain physiotherapeutic exercises provide a new ray of hope.

Cardiovascular Complaints

- **Causes**—it includes varicose veins, high blood pressure and occurs due to erect posture adopted during long standing operating procedures.
- **Prevention**—proper positioning of doctor should be maintained.

Radiation Hazards

- **Cause**—they are responsible for causing changes in blood, skin problems, tumor development, shortening of life span and mutations.
- **Prevention**—use of lead partitions, lead aprons and cubicalization of patients in protective cabins of lead glass. Regular check-up of machines for radiation leakage. Periodic health checks-up of the operator.

Sound Hazards

- **Causes**—air driven, high speed handpieces operating from 3900 to 12,500 Hz and electric engines are main contributing factors towards sound pollution. Hearing loss, acoustic stress and impaired power of concentration first affect the individual who are regularly exposed to frequencies above 3000 Hz.
- **Prevention**—personal evaluation by routine otologic and audiometric examination. Noise attenuation by repair and replacement of defective items, especially high speed drills. Treatment rooms should be made acoustically satisfactory. Personal protection by using ear plugs and muffs which reduce high intensity sounds by 30 to 35 dB.

Light Hazards

- **Causes**—dull light or too much bright light can be hazardous. Ultraviolet radiation used to polymerize sealant and composite restorations can be hazardous and may cause skin cancer and chromosomal changes.
- **Prevention**—protective eye glasses for clinician, auxiliaries and patient with regular ophthalmic consultation is a must.

Hazards due to Materials Used

- **Mercurial hazards**—it can be absorbed through skin and gastrointestinal tract but more commonly, poisoning results from absorption of vapors via lung. It is discussed in detail in chapter of pigmentation. Prevention should be done as follows
 - **Education**—health education regarding hazards due to mercury toxicity.

- *Structural design*—well-ventilated operatory and a proper structural design.
- *Floor covering*—floor covering of nonporous polyvinyl chloride.
- *Avoid room heaters*—avoiding room heaters and sterilization equipments in working areas, to minimize evaporation of mercury.
- *Proper storage*—proper storage in sealed plastic containers.
- *Nontouch technique*—use of nontouch technique during preparation of mercury.
- *Cleaning*—immediate cleaning of mercuric spills and use of water sprays or suction, to prevent release of mercury dust.
- *Periodic health surveillance*—periodic health surveillance by measuring mercury vapor levels.
- *H₂O₂ 30%*—accidental fall of such chemical can cause itching, bleaching and considerable burning of the affected part.
- *Nitrous oxide*—if used in high concentrations during anesthetic administration, it may cause increased absorption and thereby liver and kidney damage with neuralgic disease and congenital abnormalities.
- *Volatile oils*—oil of clove and eucalyptus oil used in dentistry can cause mild burns.
- *TCA and phenol*—their overzealous use can injure both, the patient and the doctor.
- *Root canal sealers*—they have one or more contact allergens and thus cause hypersensitivity and dermatological problems.

Consumer Protection Act (CPA/COPRA)

Surgeons are, at times, the privileged targets of school of law. Intentional damage to the patients and his minors definitely reaps a liability suit to the dentist but in many cases, the innocent surgeons are clutched by these laws thereby damaging the personal and professional ethics.

Introduction

In recent period, the CPA has created a great stir amongst the medical profession on the ground that it would be extremely damaging to the profession and the public service. It was brought into existence in 1986 during which medical service was not included. In April 1995, the national commission, on appeal from Kerala state commission decided that medical service should be covered under CPA.

Consumers section 2(d) of CPA defines consumer is a person who buys goods for a consideration which has been

paid or promised or partly paid and partly promised under any system of different payment. He is the one who hires or awaits of any service or services including any beneficiary. It includes user or beneficiary of goods or service, other than the person who actually buys goods or hires / awaits service where such use is made with the approval of the purchasers.

According to section 2 (o) of the act service means service or any description which is made available to potential users, but does not include the rendering of any service free of charge or under the contract of personal service.

Purpose of Act

CPA 1986 is not a substitute for the existing civil remedies. The redressal machinery set up under the CPA 1986 is an additional facility as stated under section (3) of the act itself. This section says that the act shall be in addition and not in derogation of provision of any other law for the time being in force.

The CPA was brought into existence for the protection of interest of the consumer and for the settlement of consumer disputes with limited time frame and with fewer expenses. This enables consumer to make a complaint to a redressal forum in respect of defective service, if the service has been paid for.

It provides for establishment of consumer councils and other authorities for the settlement of consumer disputes and for matter connected therefore.

The district, state and national commission empowered as '*quasi-judicial bodies*' has been established which looks into complaints of consumers where deficiency of service have come to the notice. These quasi-judicial bodies observe the principle of natural justice and are empowered to give relief of specific nature and award, wherever appropriate, compensation to consumer.

Advantages

- *Free*—administration of justice under the CPA is totally free. Consumer court do not levy court fee in respect of legal proceedings.
- *Speedy justice*—consumer courts are expected to deliver speedy justice.
- *Own lawyer*—you can be your own lawyer before consumer courts, though appointment of lawyer is not prohibited. Consumer court does not encourage appearance of lawyer and extensive long-winded arguments.
- *Procedural simplicity*—procedural simplicity and amicable atmosphere prevailing in consumer courts is more encouraging to an ordinary litigant as compared to lengthy and procedure oriented civil court proceedings.

Machinery

- *District level*—district consumer dispute redressal forum to be chaired by district judge and two other members, one of whom should be a man of good reputation and other should be a lady social worker. At district level, claim for compensation towards damages was fixed to a maximum of one lac at the starting which has been enhanced subsequently to rupees of five lacs in 1993.
- *State commission*—it is for cases where compensation is claimed for more than rupee five lacs but less than twenty lacs. The complaint should be lodged before the state consumer dispute redressal commission which is chaired by high court judge and two other members as selected in case of district redressal forum. In this forum, an appeal against orders passed by district forum can be made.
- *National commission*—it is for cases where compensation claimed for is more than twenty lacs. The complaint has to be lodged before the national body, i.e. national consumer redressal forum. This body is constituted by a judge of Supreme Court selected by Union Government to act as a president of forum with four other members including a lady member. It has been empowered to consider appeals arising from orders passed by any state commission. It is the apex body of redressal forum and has a revisional power.

Procedure

- *Filing of complaint*—complaint is filed by consumer or any voluntary consumer organization registered under Society Registration Act, 1860 or under Company Act, 1956.
- *What complaint means*—complaint means any allegation in writing made by complainant in regard to one or more of the following:
 - That he has suffered loss or damage as a result of any unfaired practices adapted by any doctor.
 - The service mentioned in complaint suffers from deficiency in any respect.
- *Timing of complaint*—as provided under section 24(A) of CPA the complaint has to be filed within two years from the date on which cause of action arises. The complaint has to be filed in any redressal forum subject to its jurisdiction.
- *Content of complaint*—a complaint should contain
 - Name and description and address of complainant.
 - Name and description and address of opposite party.
 - The fact relating to complaint and when, where it arose.
 - Document if any in support of allegation containing the complaint.
- The relief which the complainant is seeking.
- The complaint should be signed by complainant or his authorized agents.
- *Period for giving reply*—after receiving the complaint copy of complainant, it has to be sent to opposite party directing him to give his version case within a period of 30 days which may be extended to 45 days.
- *Chance for appeal*—appeal against order of district forum lies to state forum which in turn lies to national commission.
- *Timing of appeal*—appeal has to be filled within 30 days of verdict. No fees have been prescribed for filling the appeal. Appeal has to be accompanied by certified true copy of order of district forum and reasons for filing appeal should be specified.

Medical Service and CPA

- *Charged service*—in the act itself, there is no mention of medical service but a supreme court judgment by a bench comprising of three judges have held that doctors and hospitals who render service as medical practitioners are accountable for any act of medical negligence and ruled that they can be sued for compensation under the CPA provided the service has not been rendered free. Service rendered to a patient by registered medical practitioner, except where doctor renders service free of charge to every patient or under a contract of personal service by a way of consultation and treatment, both medical and surgical would fall within the ambit of services.
- *Free service will not come under CPA*—services rendered free of charge by RMP attached to a hospital or nursing home or a medical officers employed in a hospital or a nursing home, where such services are rendered free of charge to everybody, would not be the service as defined in the act.
- *NGO service will not come under CPA*—services rendered at non governmental hospital or nursing home where no charge, whatsoever is made from any persons awaiting the service and all patients (rich and poor) are given free service is outside the expression 'service'.
- *Paid NGO service*—services rendered at a non-governmental hospital or nursing homes; where charges are required to be paid by persons, who are in position to pay and rendered free of charge for patients who can not pay fall within ambit of expression 'service', irrespective of the fact that the services are rendered free of charge to persons who are not in position to pay.
- *Free government service*—services rendered at the government hospital health center or dispensary where no charge whatsoever is made from any persons awaiting the service and all patients are given free of

service is outside of preview of the act. The payment of token amount of registration purpose only at hospital or nursing would not alter the position.

- *Paid government service*—service rendered at the government hospital health center or dispensary, where service are rendered on payment of charge and also render free of charge to other persons awaiting such service, would fall of the fact that service is rendered free of charge to person who do not pay for such service.

III Effects of CPA

- *Doctor patient relationship*—it is contention in medical profession in general that the act itself during formulation, did not mean to include the services of a doctor rendered to his patients as doctor patient relationship is something more than consumer trade relationship. This act will totally disturb the doctor patient relationship which is considered to be noble.
- *Extreme laboratory investigation*—it will lead to undesirable tendency in doctors, particularly in general practitioner and new graduates, to be more invasive of their responsibilities towards the patients and refer more number of patients or cases to specialists and to advise extensive laboratory investigations which will make their position comparatively safe; without the improvement of clinical mind and experience; thereby making the treatment of general population to be costlier even up to the extent of being beyond the reach of many.
- *More patient treatment charge*—doctors will develop a tendency to assure himself free from dangers of paying compensation by sticking to different professional indemnity insurance firms which are bound to crop-up to make a good business by taking advantage of this system. As a consequence of all this, patients will be charged more than what they are presently charged.

Introduction

Forensic odontology is the subject concerned with the application of medical and paramedical science knowledge to certain branches of law, both civil and criminal. The medicolegal information obtained from the examination of teeth and jaws falls in the preview of forensic odontology. Upon exposure to physical injury and putrefaction, the human dentition, the enamel of which is the hardest substance in the body outlasts all other tissues. The material used in restoration is also extremely resistant to destruction by chemical and physical elements. The fundamental principles of dental identification are those of *comparison* (when antemortem records of the proposed deceased are available) and *exclusion* (when antemortem records of other persons are available). In the absence of the antemortem records attempt to elicit dental information is made by interrogating the relatives and friends of the deceased, which may frequently prove unreliable.

Forensic odontology may be defined as the application of dental science to the administration of the law and the furtherance of justice.

Scope of Forensic Odontology

- *Record preparation*—the correct handling and examination and the proper preparation and presentation of dental evidence in both civil and criminal legal procedures.
- *Identification*—personal identification, either individually or in context of mass disasters.
- *Age assessment*—to calculate the age of patient.
- *Bite mark investigation*—investigation of criminal cases where bite marks are involved and the interpretation of bite marks.

- *Human abuse*—recognition of domestic, and child abuse.
- *Lip print*—comparison and identification of lip print.
- *Legal aspect*—legal aspect of dental traumatology.

Record Management

- *Content*—the dental record is a legal document of dentist which contains information about subjective and objective finding of the patient. It also includes pathological report, radiographs, and clinical photographs of the patient.
- *Treatment plan*—treatment plan which is given to the patient should be updated in the record. All the letter of reference, letter of consent, insurance and financial statement should be store in the record of the patient.
- *Progress note*—the progress note of the patient should contain information about the restorative and therapeutic procedure which are carried out on to the patient.
- *Record of telephonic conversation*—summaries of the telephonic conversation with the patient, consultant, insurance company representative and legal authorities should be maintained in the record.
- *Signing of record*—record should be signed by the personnel. Any change made in the record should not erased but a line should be crossed on it, so that it is readable. This will help to remove any fraud intention to alter record.
- *Electronic maintenance of dental record*—it is common nowadays that dental record to be maintained electronically. Nowadays some software programs are developed to maintain patient dental information. This is advantageous as it can be easily networked and transferred.
- *Storage of record*—record should be kept minimum of 7 to 10 years. In the case pediatric patient record should be maintain until the patient reaches the age to maturity.

Identification

Forensic odontology is concerned with the identification of both living and deceased person.

Role of Teeth in Establishing the Identity

Dental Comparison

Dental comparison affords a potentially straightforward and simple means of establishing identity. The method of dental identification depends upon:

- *Resistance of dental tissue*—the relative resistance of the mineralized dental tissues and dental restoration to changes resulting from decomposition or harsh environment extremes such as conditions of temperature and violent physical forces.
- *Individual characteristic of dentition*—the unique individual characteristic of the dentition and dental restoration.
- *Antemortem record*—the availability of documentation of the antemortem status of the dentition in the form of dental treatment records and diagnostic radiographs.

Each individual has 32 teeth with 5 surfaces each with their own character of size, shape, position and spacing with the result that no 2 sets of teeth are alike (**Fig. 50-1**). Teeth extracted after death leave a completely different socket from those removed during life. When the tooth is removed or dental work of any sort is carried out the teeth pattern is changed and its record may exist with the dentist. In natural decomposition teeth are practically indestructible. They are not easily destroyed by fire. Being sheltered in the oral cavity they are generally not damaged. Teeth as well as dentures made of acrylic resin are generally resistant to the action of corrosive acids. The identification from data of authenticated teeth depends entirely upon the accuracy and completeness of authenticated records made during life. The record should include:

- *Number of teeth*—the number and situation of teeth present and number and situation of teeth lost.
- *Arrangement*—arrangement, irregularities, erosion, caries, fillings, bridge crown work and dentures.
- *Shape of arch*—exact shape of edentulous arch should be noted down.
- *Identifying features*—some of the common identifying features of teeth pertain to faulty development, faulty alignment, presence of stains, localized wear on certain teeth and missing teeth.
 - *Faulty development*—teeth may be undersized, oversized, notched or present some other irregularity as a result of faulty development and malformation. Hutchinson's teeth constitute a classical example of

malformation of the incisor in congenital syphilis. These changes are most conspicuous in central incisors which are usually small, widely spaced, notched and less broad at the cutting edge than at the gum margin giving them the appearance of tip of screw driver.

- *Faulty alignment*—the defect in the alignment may be in the space between teeth, e.g. widely spaced teeth or overriding teeth. Between the teeth of the upper and lower jaw when there is protrusion of upper incisors resulting in overlap of lateral incisors the bite pattern is known as overbite and the reverse pattern is known as crossbite.
- *Stains*—Pan (betel leaf, tobacco) chewing habit stains the teeth with dark brown or black deposits. Yellowish or dark brown stain on the back of incisor teeth is common in cigarette smokers. Chalky white or yellowish brown areas of discoloration are found in fluorosis. Metal poisoning may cause pigmentation of gums and thereby suggest a cause of death. Copper causes green and mercury and lead a blue black line on the gums. Gum hyperplasia induced by phenytoin may aid in identification and suggest epileptic seizure as a cause of death.
- *Localized wear on certain teeth*—A pipe smoker may have localized wear on teeth either on incisors or at angle of mouth due to position of pipe. Notched incisors from holding thread, pins, nail, between teeth on day to day basis may suggest the occupation of tailor or hairdresser or cobbler.
- *Missing teeth*—The missing tooth may have been lost antemortem or postmortem. Ante mortem loss of teeth due to trauma at or near the time of death if frequently associated with fracture of thin bony plate surrounding the alveolus. In loose tooth which has fallen out it is not so. Extraction or tooth loss in living person is followed by bleeding from its socket which stops in about 24 hrs or sometimes 2 to 3 days when the clot forms in the raw socket. By about 14 days, the clot is obliterated by fibrous tissue and the alveolar rim is smoothened by resorption of bone. By about 5 to 6 months, gradual new bone formation fills the socket but its outline is still visible on X-ray examination. By about 6 months to 1 year remodeling of new bone completely obliterates the socket leaving a slight depression and the socket outline is not visible on X ray examination. In recently recovered remains postmortem tooth loss discloses a clean socket devoid of blood clot. In skeleton in which postmortem loss of teeth is common, the bony rim of alveolus is sharp and feathered.

Procedure in Dental Identification

- *Area covered*—it should include not only the oral cavity of the victim but when applicable, the surrounding scene as well, especially in case of conflagration or injuries when only the remnants of the dental arches may remain scattered and rubble and debris. Dental examination in mass disaster victims often by necessity must be accomplished under accident site and/or temporary mortuary.
- *Recovery of dental structure*—the task of dental identification begins at the site of discovery of the body. When the gross postmortem changes affecting the teeth have occurred, such as charring, disintegration and fragmentation in fires and high impact accident, meticulous care in their recovery and conveyance to the mortuary are of utmost importance. Displaced teeth in decomposed bodies or skeletal remains should be saved, labeled and later secured to the intraoral position using adhesive cement (**Fig. 50-1**). Most open alveoli are the result of postmortem tooth loss. In recently recovered remains postmortem tooth loss disclose a clean socket devoid of blood clots.

Fig. 50-1: Human dentition consist of 32 teeth with 5 surfaces.

- *Instrument*—instruments used for dental examination include explorer, mirror, tissue forceps, heavy duty autopsy scalpel, handle and blades, tissue clamps, irrigating syringe, rubber autopsy gloves, polythene specimen bags, gauze sponges (for tooth cleansing) and a source of illumination (flash light or battery operated head lamps); and dental examination form should be used.
- *Reconstruction and examination*—examination should be performed by two persons thoroughly familiar with dental terminology, one actually performing the examination and one recording the data. The recorder should view the actual teeth in order to record the basic morphological pattern of the restoration or cavities. In

some cases, it is necessary to remove the jaw from the body for more detailed examination and future reference.

- *Transcription of dental records*—the point to be considered while charting are missing teeth, unerupted teeth, supernumerary teeth, restoration, prosthesis, dentures, decayed, broken teeth, mal position, overlapping, crowding and spacing, peculiar shape of teeth.
- *Identification of edentulous bodies*—frequently dentures are present in the mouth of unknown bodies or may be found elsewhere. If the denture can be identified and it can be shown to fit the mouth of the deceased, a reliable identification can be made. The most reliable means of identification of denture is for them to be permanently marked with the name of the patient or some code during manufacture.

Problems in Identification

Condition of material recovered

- It depends upon the circumstances surrounding the death and the care exists in its collection and transport.
- Incineration produces damage to teeth ranging from mild scorching of the surface to severe charring of the enamel and dentine with crumbling of the crown.
- Sustained very high temperature will result in calcinations of the teeth with considerable overall shrinkage.
- Burnt teeth are usually very fragile and suffer separation of the enamel and often gross disintegration of the crowns.
- In high impact accidents such as aircraft and high speed road crashes much mechanical damage can occur and teeth and jaws may fracture and disintegrate.
- Failure to recover significant material may result in failure to identify a body.

Errors in examination—errors can easily be made in the examination and recording of the postmortem dental material.

Inadequate antemortem data—errors in charting teeth treated and insufficient descriptive details about the treatment provided are common. Other difficulty arises when a dentist has retired and destroyed his records.

Technique for Identification in Mass Disaster

These include X-ray, UV light, postmortem serology and DNA profiling.

X-ray

All bodies which are found under suspicious circumstances and which are rendered unrecognizable due to prolonged immersion in water, burning by fire and acid or by any other destructive means such as explosion should

be routinely X-rayed. A dental radiograph when available constitutes one of the most valuable pieces of evidence for identification purpose. Panoramic X-ray technique provides excellent pictorial dental record (**Fig. 50-2**).

Fig. 50-2: Panoramic radiograph provides excellent record.

The CAPMI (computer-assisted postmortem identification) system compares dental record of victims of mass disaster and enables rapid identification of air crash, flood and explosion victims. Radiography can provide information in relation to age, sex, race, and occupation, diagnosis of certain conditions and identification and cause of death.

Age—Age can be established by radiography of bones and teeth (for root calcification). Calcification of costal cartilage and osteoarthritic changes in large joints and the spine also help.

Sex and race—may be deduced by radiography in some cases.

Occupation—this can sometimes be deduced from X-ray. The whole range of pulmonary occupational diseases such as silicosis, asbestosis may show specific radiographic findings. The radial artery in laborer's using pneumatic drill may show calcification; coal carriers and professional wrestlers are liable to calcified lesions of the ligamentum nuchae. Football players may show calcified hematoma of the thigh muscle.

Identification—it is possible by comparison of postmortem and antemortem X-ray (**Fig. 50-3**).

Cause of death—fracture of bones seen on X-ray may indicate their antemortem origin and these include depressed fracture of skull, fracture of hyoid, fracture dislocation of cervical vertebrae, severe injury to bones by cutting instrument or fracture of several ribs which are incompatible with life. Foreign bodies in the upper respiratory tract provide valuable clue. Evidence of poisoning by heavy metals and signs of diseases such as malignant growth may be apparent.

Fig. 50-3: Intraoral periapical radiograph will help to identify the victim on the basis of radiopaque filling.

UV Rays

An ultraviolet lamp can be used to locate and define tattoo marks and scars on burned and decomposed remains, and to segregate bones in cases of mix-up. When examined by UV light washed blood stains are readily seen and seminal stains give a bluish white fluorescence.

Postmortem Serology

A known postmortem grouping of an individual serves to narrow the range of possible identities. Even in putrefied bodies, blood group antigen may be detectable for serological studies. The bone marrow in skeletal remains may still retain serologically detectable antigens.

DNA Profiling

This is useful if suitable tissue (blood, semen stored in bank) is available. If such tissue is available a DNA profiling or autopsy derived tissue should be compared by single probe analysis with that of parent, children, sibling and if be necessary other relatives. This is now used worldwide in aircraft and other major accidents. The techniques which are used for DNA profiling are Restriction fragment length polymorphism (RFLP) and polymerase chain reaction (PCR). RFLP results in splitting source DNA into thousand of fragment. PCR can do evaluation of denture DNA or minute quantity of DNA.

Age Assessment

Chronological age assessment may be an important factor in establishing the identity of the living or deceased person.

It is also important in legal proceedings when specific charge for particular offence may depend on whether the alleged offender is a juvenile.

Visual observation—stage of eruption of the teeth and evidence of changes due to function such as attrition can give an approximate estimate of age.

Radiography—it can provide a great detail, the gross stage of dental development of the dentition.

Histological—it requires preparation of the tissue for detailed microscopic examination, which can determine more accurately the stage of development of the dentition.

Physical and chemical analysis—it is done to determine alterations in ion levels with age have been proposed.

Bite Marks

One of the two major interests of the forensic odontologist is one that has direct relevance to the pathologist, in that it concerns the interpretation of trauma to the body surface. Dental evidence is used to identify the perpetrators of a crime who happened to have left their teeth marks in some substances left at the scene. Generally, it is easier to exclude a certain person than to identify one conclusively from the bite mark.

Definition

A bite mark is a patterned injury produced by teeth on animate or inanimate objects, is caused by small enamel defects on the incisal edge of incisor teeth creating individual characteristics during biting procedures. It can be:

- *Tooth mark*—mark left by a tooth (human or non-human).
- *Arch mark*—mark produced by four or five adjacent teeth in the same arch (**Fig. 50-4**).

Fig. 50-4: Bite marks on inmate subject presented as arch.

Causes

- *Child abuse*—it can be found anywhere on the body, favorite sites being the arms, hands, shoulders, cheeks, buttocks and trunk. Most of the time it is inflicted by the mother.
- *Sexual assaults*—it usually occurs in cases of rape. Most common site of it is breast and nipples but neck, shoulders, thighs, abdomen, pubis and even vulva may be attacked.
- It may also be inflicted on police officers when attempting to arrest resisting offenders.
- *Sports*—bites can occur in sporting events especially football and some forms of wrestling. In this, it can occur anywhere but hands, fingers, nose, forearms, ears and even lips may be target.
- *Self inflicted*—falls onto the face or a fit may cause the tongue and lips to be badly bitten. Some persons deliberately bite themselves, sometime to fabricate injuries for a variety of motives ranging from gain to psychiatric disorders.

Importance of Bite Marks

It can permit precise identification because the alignment of teeth is peculiar to each individual (**Fig. 50-5**). The mark may be on the article of food found at the scene of crime or on human being to realize that a bite on human flesh can have marks not necessarily due to break in the continuity of the skin but due to a small subdermal or thin deep hemorrhage.

Fig. 50-5: Bite mark is represented distorted image of human dentition.

Bite marks are always contaminated by saliva and therefore contain amylase, ptyalin and blood group which can be determined by the cast of suspect of mouth is made and transparency of his bite compared to that of the unknown bite. It should be remembered that bite marks on skin are modified by its elasticity when the teeth are withdrawn.

Method of Preservation of Bite Marks

The doctor should be asked how the bite mark may be best preserved. When the substance is plastic such as butter, cheese, lard, or chocolate, it should be stored in a refrigerator to prevent melting or gradual flowing. It should not be deep frozen as this may cause brittleness and cracking. Fruits should be preserved in Campden solution, a metabisulphite fluid used for fruit bottling. If it is not there then 5% acetic acid in 40% aqueous formaldehyde solution can be used.

Whatever preservation is recommended, the object should be adequately photographed with film plane at right angles to the bite and a scale placed in the focal plane. Death freezes a bite mark but a subdermal hemorrhage in living person disappears within 20 minutes hence it is important to take an immediate photograph of the bite mark.

Classification of Bite Marks

- *Non-human (animals)*
- *Human*
 - *In foodstuffs* (in a part eaten foodstuff abandoned by offenders at the scene of crime).
 - *On non-biological object* (on pencils, pipe stems and detonators).
 - *In human skin*
 - Non-criminal (erotic bite)
 - Criminal—it can be offensive (upon victim by assailant) and defensive (upon assailant by victim).

Bite Marks on Foodstuff

Foodstuff bite marks can be classified into 3 types:

- *Type I*—bites that are found in material such as chocolate, which fracture readily with limited depth of tooth penetration.
- *Type II*—bites formed in foods where teeth obtain a good grip and then bitten piece is removed by fracturing it from main material, e.g. apples.
- *Type III*—bites in which teeth bite right through the bitten material, e.g. cheese. These bit exhibit extensive scrape marks and may give an indication of the relative position of upper and lower incisor teeth in centric occlusion.

Depth of penetration of the teeth—where there is only minimum penetration of teeth into the food, the record is of

biting edges and where there is greater penetration the record is of the labial aspect of the teeth.

Time and temperature—bite mark in foodstuff may produce the exact mesial-distal dimension of the teeth provided the record is taken immediately after the bite was made. Dimensional and color changes are expected to occur in the foodstuffs due to effect of temperature.

Bite Marks in Human Skin

Human tissue has been described as one of the least dependable substances for the registration of bite marks as the bite marks in the tissue is affected by several variables.

Status of the Tissue

Site—type of tissue/condition of skin. For example loose skin or excessive subcutaneous fat commonly demonstrated easy and extensive brushing leading to a poor bite mark definition. Areas of fibrous tissue or high muscle content tend to bruise less easily and thus are more likely to demonstrate a bite mark.

Age—infants and elderly individual tend to bruise more easily than other age groups marking the detection of bite marks more difficult.

Sex—females tend to bruise easier than males. Once produced a bite mark will be evident for a longer period of time on females as compared to males.

In human bite mark can be sexual (**Fig. 50-6**) or assault (**Fig. 50-7**) type.

Fig. 50-6: Sexual bite mark.

The Influencing Factor

Bite mark can be influenced by time elapsed between the actual biting and when the impression is made. Depression of the skin as occurs in most bite marks will recover within

Fig. 50-7: Assault bite mark.

6

10-20 minutes after the bite, although discoloration and swelling may be present 24-72 hours on a living object.

The force exerted—the skin appearance of bite mark may vary from bruising, abrasion, and indentation to actual lacerations.

The number of teeth—in general the more teeth marks present in the bite marks, the better is the likelihood of identification utilizing that bite mark.

The type of teeth—in many cases the bite mark is seen to be comprised of the upper anterior teeth. The investigator should take note of the width of teeth.

The reaction of the surrounding tissue—bite marks made hours or days before the event will show inflammatory changes and signs of healing microscopically.

Types of Bite Mark

- Definite bite mark
- Amorous bite mark
- Moderately aggressive bite mark
- Aggressive bite mark
- Very aggressive bite mark

The Nature of Bite Marks

Though called bite marks, but sometimes it may not be from actual teeth. The lips can transiently mark the skin, if forcibly nipped, especially on children. Suction can produce a crop of punctate hemorrhages, either small petechiae or larger ecchymoses merging into a confluent central bruise.

It is caused by front teeth from canine to canine with a gap at either side representing the separation of upper and lower jaw.

A human bite is near circular or a shallow oval. A deep parabolic arch or 'U-shaped' can only be animal in origin. The teeth may cause clear, separate marks or they may run into each other to form a continuous or intermittently broken line. As the time progresses original teeth marks spread out and blur. Teeth marks may be abrasion, bruises or laceration or a combination of any two of three. The clarity of bite marks depends on a number of factors:

- If the contour of the part bitten is irregular or markedly curved, then only part of dental arch is in contact with the tissues.
- If the bite is forcible, then extensive subcutaneous bruising may spread and blur the outline.
- If the bite is inflicted many days before, then healing of abrasion and lacerations and absorption of bruising will leave progressively less detail.
- When the teeth are forcibly applied the typical appearance is of two 'bows' with their concavities facing each other and a gap at each end.
- *Love bites*—they are caused by firm application of the lips, which form an airtight seal against the skin, and then sucking action reduces the air pressure over the center. This causes shower petechial hemorrhage to appear from rupture of small venules in the superficial layer of the subcutaneous tissue. If forcible the petechiae are confluent and a frank bruise or even hematoma develops.

Investigations of a Bite Mark

Firstly the bite mark should be carefully and fully photographed. The photograph should be taken from different angles, but especially from directly perpendicular viewpoint, with the plane of film at right angle to that of the lesions. An accurate scale should always be held near the lesion, as close as possible. The lesion should almost fill the camera frame in some shots to capture as much detail as possible. When photography is completed, swabs of the bite should be taken to try to recover saliva. Plain cotton-wool swab are gently rubbed onto the bite. They should be then deep frozen unless send straight to the serology laboratory.

After this, impression of the bite can be taken (Figs 50-8 and 50-9). It is done by laying a plastic substance over the bite mark, which then hardens, so as to produce negative cast of the lesion (Fig. 50-10). It is usually made with a rubber- or silicone-based medium containing catalytic hardeners. Less satisfactory substances are water based pastes, such as plaster of Paris, which are put on wet and allowed to dry before removal. But they have a disadvantage

Fig. 50-8: Sample bite taken on apple

Fig. 50-9: Impression is taken of the bite and cast is made.

Fig. 50-10: Study case is made.

of potential damage to the actual bite. After autopsy, it is also possible for the whole area of the skin carrying the bite to be removed and preserved in formalin for future examination.

Matching the Bite Mark with the Suspect Dentition (Figs 50-11 to 50-14)

The teeth of those who are either suspected by the police or who had access to the victims should be examined. In most jurisdictions, it is vital that fully informed consent should be obtained from the persons beforehand.

Any refusal must be a bar to any further action. When children are concerned, usually in the setting of child abuse, the consent of fully informed parents or guardian must be

Fig. 50-11: Bite mark of suspect is taken.

Fig. 50-12: Positive replica of bite mark is made.

Fig. 50-13: Cast of suspect is made.

Fig. 50-14: Cast is matched with previous mark.

obtained. Then dentition is examined for number of teeth, missing teeth, complete or partial denture, occlusion, broken teeth, irregular teeth and abnormalities of the teeth. Photographs of dentition of the patient can be taken.

After that impression of bite of suspect should be taken. Tracing can be made from the positive cast of a bite impression, inking the cutting edge of front teeth and transferring these to transparent sheets, which can then be laid over the photograph to determine correspondence.

Classification of Skin Wounds

Abrasion—it is superficial type of injury only skin part is involved, i.e. both epidermis and dermis. It heals without the scar formation. It is of following types:

- **Graze**—abrasion caused by friction between skin and hard surface.
- **Scratch**—it is caused by pointed ends of nails, pins, needles, etc. It is localized linear abrasion.
- **Imprint abrasion or pattern abrasion**—it gives the pattern of object on the skin. For example teeth bite.
- **Bruise or contusion**—subdermal-extravasation of blood from rupture of subcutaneous vessels and capillaries of skin and organs.
- **Laceration**—wound must be produced with a blunt object that penetrates the skin to subcutaneous tissue.
- **Incised wound**—must be caused by sharp edged object like knife. In incised wound length is more as compared to width and depth.
- **Stab wound**—it is caused by pointed end of sharp edged or blunt object. Depth is more as compared to width and length.

Contusion and abrasion are described in two dimensions, i.e. length and width.

Laceration, incised wound and stab wound described in three dimensions.

Medicolegal Aspects of Dentistry

The Dentist Act 1948

The act was passed to regulate the profession of dentistry in general and to constitute the Dental Council of India and for a register called 'Indian Dentist Register'. It also provides for the constitution and composition of the State Dental Council and for State Register of Dentists.

Duties of Dental Council of India

- To maintain the dental register.
- To regulate dental education.
- To recognize the foreign dental qualification.
- Appeal against disciplinary action.
- To give warning notices to dentist for his/her misconducts.

Duties of State Dental Council

- To maintain dentist register.
- To take disciplinary control.
- To give warning notice to dentist for his/her misconduct.

Hippocrates Oath: The Declaration of Geneva

- I solemnly pledge myself to consecrate my life to the service of humanity.
- I will give my teacher, the respect and gratitude which are their due.

- I will practice my profession with conscience and dignity.
- I will respect the secrets which are confided in me.
- The health of my patient will be my first consideration.
- I will maintain by all the means in my power, the honors and the noble tradition of the medical profession.
- My colleagues will be my brothers.
- I will not permit consideration of religion, nationality, race, party, politics or social standings to intervene between duties to my patient.
- I will maintain utmost respect for human life from the time of conception, even under threat; I will not use my medical knowledge contrary to laws of humanity.

Rights and Privileges Enjoyed by Registered Dental Practitioner

- Right to choose the patients.
- Right to use title and description of the qualification which is actually possessed.
- Right for appointment in public and local hospital.
- Right to prescribe and/ or dispense medicine to his patients.
- Right to realize fee and other expenses.
- Right to issue medical certificates and medicolegal reports regarding dental problems.
- Right to evidence in a court of law as an expert witness.
- Right to exemption from serving as a juror at an inquest.

Duties of Dental Practitioners

- Duty to exercise a reasonable degree of skill and knowledge.
- Duties with regard to attendance and examination.
- Duty to furnish proper and suitable medicines.
- Duty to give instructions.
- Duty to control and warn.
- Duty towards children and adults incapable of taking care of themselves.
- Duty to inform patient of risks.
- Duty to notify certain diseases.
- Duties with regards to operation.
- Duties under Geneva conventions.
- Duties with regard to consultation.
- Duty in connection with X-ray examination.
- Professional secrecy.

Professional Misconducts

- Adultery.
- Improper conduct or association with patient or member of patient's family.
- Conviction by court of law.
- Issuing false certificates.

- Withholding from health authorities information of notifiable disease.
- Performing or enabling an unqualified person to perform an abortion or any illegal operation for which there is no indication.
- Violating the provisions of the Drug Act.
- Selling scheduled poisons to the public under cover of his qualifications.
- Using of touts and agents for procuring patients.
- Disclosing the secret of a patient.
- Association with manufacturing firms.
- Advertising.
- Professional association with bodies or societies of unqualified persons formed for the purpose of turning unqualified practitioner.
- Running an open shop for sales or medicines for dispensing prescription of other doctor or for sale of medical and surgical appliances.
- Refusal to give professional service on religious grounds.
- Drunk or disorderly so as to interfere with proper skilled practice or medicine.

Precautions Against Negligence

- Obtain informed consent of the patient.
- Establish good rapport with the patient.
- Keep full, accurate and legible medical records.
- Employ ordinary skill and care at all time.
- Confirm diagnosis by laboratory tests.
- Take skiagrams in bone or joint injuries or when diagnosis is doubtful.
- Immunization should be done whenever necessary particularly for tetanus.
- Sensitivity tests should be carried out before injecting preparations which are likely to cause anaphylactic shock.
- Seek consultation where appropriate.
- In suspected cases of cancer all laboratory investigations should be done without delay to establish early diagnosis.
- Do not criticize or condemn the professional ability of another doctor especially in the presence of the patients.
- Do not make statements admitting fault on your part.
- Avoid firm overconfident prognosis and promising too much to patients.
- Never guarantee a cure.
- Inform the patient of any intended absence from practice or recommended or make avail of a qualified substitute.
- Transfer the patients if facilities are inadequate to handle his problems.
- The drug should be identified before being injected.
- Obtain consent for an operation or giving anesthesia.
- No experimental procedures should be adopted without the consent of the patient.

- No procedures should be undertaken beyond one's skill.
- Keep yourself informed of technical advances and use standard procedures of treatment.
- Frequently check the condition of equipments and use safety installations.
- Proper instructions should be given to patient and proper postoperative care should be given.
- The patient must not be abandoned.
- No female patient is examined unless a third person is present.
- Do not order a prescription over the telephone.
- Anesthesia should be given by qualified medical professional only.
- Do exercise care in the selection of assistants and allotting duties to them.

Penal Provisions Applicable to Medical Practice

- *S.176 IPC*—omission to give notice or information to public servant by person legally bound to give it.
- *S. 177 IPC*—furnishing false information.
- *S.191 IPC*—giving false evidence.
- *S.192 IPC*—fabricating false evidence.
- *S.193 IPC*—punishment for false evidence.
- *S.197 IPC*—issuing or signing false certificate.
- *S.201 IPC*—causing disappearance of evidence of offence, or giving false information to screen offender.
- *S.203 IPC*—giving false information respecting an offence committed.
- *S.204 IPC*—destruction of document (or electronic records) to prevent its production as evidence.
- *S.39 cr. P.C*—every person aware of the commission of

the intention of any other persons to commit any offence punishable under IPC, shall forth give information to the nearest magistrate or police effective of such commission or intention.

- *304 (A) IPC*—causing death of the patient due to rash or negligent act.
- *320 IPC*—grievous hurt—the following kind of hurt only designated as 'grievous' hurt.
 - *First*—emasculation
 - *Second*—permanent privation (loss) of the sight of either eye.
 - *Third*—permanent privation of hearing of either ears.
 - *Fourth*—privation of any member or joint.
 - *Fifth*—destruction or permanent impairing of the powers of any member or joints.
 - *Sixth*—permanent disfigurement of head or face.
 - *Seventh*—fracture or dislocation of bone or *tooth*.
 - *Eighth*—any hurt which endangers the life or which causes sufferer to be during space of 20 days in severe bodily pain, or unable to follow his ordinary pursuits.

Introduction

As there is changing era with more advance diagnostic technology coming up, nomenclature of some of the diseases should be revived and changed. In dentistry, there are many disease names which are nowadays either discarded or had been given new names. But, as it is being said difficulty lies not in new ideas but escaping old one, we many times not accept the newer terms and stick to older ones. This chapter will give emphasis on some of older terminologies and why it should not be used.

Some of the diseases in this chapter are described in detail. The reason for this is that in many parts of the world these terminologies are still used. But as a practice, we should start using new terminologies to avoid confusion in mind of budding dental professionals.

Bowen's Disease

It is localized '*intraepidermoid carcinoma*' that may progress to invasive carcinoma over many years, which is characterized by progressive scaly or crusted plaque-like lesion.

Etiology

- *Sun exposure*—this is thought to be causative factor for the Bowen's disease.
- *Arsenic ingestion*—accidental ingestion of arsenic can lead to this disease.

Clinical Features

- *Age and sex distribution*—it is common in older age group with more predilections for males.
- *Location*—it occurs on male and female genital mucosa and in oral mucosa as erythroplakia, leukoplakia or erythematous lesion.

- *Appearance*—it appears as slowly enlarging erythematous patches.
- *Skin*—there is a red and slightly scaly area on the skin, which eventually enlarges and turns into white or yellowish lesion.
- *Signs*—when these scales are removed, it produces a granular surface without bleeding.

Why Discarded

Bowen's disease nowadays synonymous with carcinoma in situ. Histologically, Bowen's disease is characterized by disorganized growth, presence of large hyperchromatic nuclei and multinucleated cells which are the same features that are seen in carcinoma in situ.

Leontiasis Ossea

The word '*leontiasis*' has been used to describe the leonine appearance of some patients with facial leprosy. Virchow added the word '*ossea*' to describe leonine appearance in bilateral bone disease of the face and thus, the term leontiasis ossea came into being.

Etiology

- *Bone disease*—most cases of leonine face are result of bone disease from two conditions i.e. *fibrous dysplasia* and *Paget's disease*.
- *Metaphysial dysplasia*—bilateral and symmetrical involvement of the face and jaws may be seen in some cases of *metaphysial dysplasia* and in *diphysial dysplasia*.
- *Periostitis of jaw bone*—some cases of leonine ossea are due to *periostitis* of the jaw bones or it may be due to *osteitis fibrosa*.

Clinical Types

- *Early childhood type*—starts early in life and quickly extends until skeletal growth ends, when the lesion ceases to grow but does not regress.
- *Young adult type*—second group starts in early years and while it progresses slowly or quickly, it does not cease with the end of somatic growth but continues its activity and may produce gross and terrible consequences.
- *Adult type*—the third type starts in early adulthood or even near the middle life and progresses slowly and inexorably.

Clinical Features

- *Appearance*—there is bilateral enlargement of the facial bones, sometimes producing the leonine appearance.
- *Site*—a classical case is one in which there is enlargement of maxilla, mandible, and malar bones and in some cases, changes in the frontal as well as ethmoid, sphenoid and temporal bones. In some cases, there is partial deformity of the face, either unilateral or bilateral, but without leonine appearance.
- *Orbit*—the orbital cavity is reduced in size and the eye is protruded. Blindness follows compression of the optic nerve or the eyeball and difficulty in breathing is the result of narrowing of the nasal passage.

Radiographic Features

- *Radiodensity*—the affected bones vary in size and density.
- *Appearance*—there may be symmetrical thickening and increased density of the bones without any leonine faces.
- *Mandibular lesions*—there is tendency of mandible to present a characteristic appearance. The inferior margins of the bone, deep to bicuspid and molar region projects downward, perhaps very markedly, while the incisor area is either unchanged or only slightly deeper than normal.
- *W appearance*—the effect of altered configuration of the mandible is that it represents a rough caricature of the letter W.
- *Cumulus cloud*—the surface of the bony projection from the inferior aspect of the mandible may present irregular appearance resembling the cumulus cloud.
- *Nose*—the nasal bone is often thickened and nasal septum may or may not be involved.
- *Frontal bone*—in some cases there is marked prominence of frontal bone over the orbits.
- *Face*—there is gross deformity of the face, with large mass of bone projecting from the mandible on one side and another, from the opposite paranasal region.
- *Skull*—the base of the skull tends to be either granular in structure or homogeneous and structureless, but very dense.

- *Marrow spaces*—in some cases the trabeculae are thickened and dense, with narrowing of the marrow spaces.

Why Discarded

Nowadays this term is never used as it requires a lot of imagination to see lion in it.

Previous or Former Cyst

Nowadays some of the names which are used to describe earlier are not in use or they are no longer suitable. It includes primordial cyst which is seen to be odontogenic keratocyst, globulomaxillary cyst which nowadays seems to be odontogenic origin as entrapment theory is not accepted. Globulomaxillary cyst is said to be radicular, lateral periodontal cyst or OKC. Other cysts which now said to be not in existence are median mandibular cyst and median palatal cyst which are variants of nasopalatine duct cyst.

Primordial Cyst

It is one of the less common types of odontogenic cysts.

Origin

- *Stellate reticulum*—it originates when cystic changes take place in the stellate reticulum of the tooth germ before any calcified enamel or dentin has been formed. So, it is found in place of a tooth rather than directly associated with it.
- *Supernumerary tooth*—it may originate from the enamel organ of supernumerary tooth or from the remnants of dental lamina.

Clinical Features

- *Occurrence*—less common and account for only 5% to 6% of cysts of the odontogenic variety.
- *Age and sex*—it is found in children and young adult between 10 and 30 years of age, although it may persist in older age group and occurs with equal frequency in both the sexes.
- *Site*—it can arise in any portion of the jaw, but most often seen in the ascending ramus of the mandible and in third molar area. It is occasionally associated with an over-retained erupted deciduous tooth.
- *Symptoms*—it has a tendency to painlessly enlarge and slowly replace large portions of cancellous bone before expansion of the cortical plate by way of which it reveals its presence. Pain which is associated with a large cyst

is caused by infection that may follow the perforation of the expanded cortical plate.

- **Aspiration**—when aspirated, they yield a thick granular yellowish material.

Radiographic Features

- **Radiodensity**—cyst-like radiolucency that is well defined and have hyperostotic borders.
- **Internal structure**—it may be unilocular or have a scalloped outline that gives it a multilocular appearance (**Fig. 51-1**).
- **Teeth**—it produces deflection of adjacent tooth root, but seldom cause any root resorption. The involved tooth is missing because of failure of the tooth to develop.
- Those in maxilla are smaller than their mandibular counterparts.

Fig. 51-1: Primordial cyst showing radiolucency in lower anterior region with missing central incisor.

Why Discarded

Nowadays this term is not used and this cyst is thought to be odontogenic keratocyst.

Globulomaxillary Cyst

It is also called '*intra-alveolar cyst*'. It occurs in globulomaxillary area. There is evidence that the cyst acutely forms in the bone suture between the premaxilla and maxilla, the incisive suture, so that location may be different. Due to this Ferenczy has suggested the term '*premaxilla-maxillary cyst*'.

Pathogenesis

- **Fissural cyst**—it was considered to be an inclusion or developmental cyst that arises from entrapped non-odontogenic epithelium in globulomaxillary suture

which occurs at the junction of globular portion of the medial nasal process and maxillary process. Previously existence of globulomaxillary cyst was disputed by Christ who said that development of anterior maxilla occurs by merging of growth center and not by fusion of facial processes so no entrapment occurs because it cannot exist. Recent embryonic studies have demonstrated that Christ's view of facial development is incorrect. Fusion of facial process does occur and epithelium is entrapped in areas that will later lie between the maxillary lateral incisors and canines. In conclusion, recent evidence favors the re-introduction of the globulomaxillary cyst as a specific pathologic entity with varying histologic features.

- **Odontogenic origin**—recent theory suggests most of cyst originating in globulomaxillary area are of odontogenic origin. This is reason nowadays, it is assumed as variant of lateral periodontal cyst, radicular cyst or OKC.

Clinical Features

- **Location**—it is present between maxillary lateral incisor and canine.
- **Symptoms**—it is asymptomatic and is discovered during routine radiographical examination. If cyst becomes infected, patient may complain of local discomfort or pain in that area.
- **Teeth**—as it enlarges, it expands the buccal cortical plate between maxillary lateral incisors and canines. This will diverge the roots of two teeth and their crown resulting in moving contact point incisally. Adjacent teeth are usually vital.
- **Signs**—mucosa over the expanding cortex remains normal in color. If cortical plate is eroded then fluctuant swelling develops. Palpation will produce crepitus. If it becomes secondarily infected, the expansion will mimic lateral periodontal abscess. Aspiration of the swelling is productive of typical amber colored cystic fluid.

Radiographic Features

- **Pear-shaped radiolucency**—it appears as pear-shaped (**Fig. 51-2**) or tear-shaped radiolucency between roots of maxillary lateral incisors and canines. Small end of the pear is directed toward the crest of alveolar ridge. The upper border may invaginate the floor of the nasal fossa or the antrum.
- **Size**—is variable and may reach the maximum level of diameter of 3-4 cm.
- **Teeth**—it may cause divergence of the roots adjacent teeth (**Fig. 51-3**). Displacement of the teeth is common. In some cases root resorption is also seen. The rotation and separation of the lateral incisor and canine roots will usually be apparent on the radiograph.

Fig. 51-2: Pear-shaped radiolucency of globulomaxillary cyst seen between lateral incisor and canine. Note there is also root resorption of teeth.

Fig. 51-3: Crop OPG showing radiolucency in lateral and canine region causing the divergence of teeth (Courtesy Dr Ashok L).

- *Lamina dura*—lamina dura of the adjacent teeth are usually intact.

Differential Diagnosis

- *Lateral periodontal cyst*—radiographically, it appears as a dome-shaped radiolucency more commonly seen in mandibular lateral incisor and first premolar region occurring in an older age group.
- *Lateral dentigerous cyst*—it is commonly associated with impacted teeth. The radiolucency is associated with the crown (attached to the neck of the tooth).
- *Primordial cyst*—it is more common in mandibular posterior region.
- *Giant cell granuloma*—it is more common in anterior region. Usually, it appears as a mandibular multilocular radiolucency.

- *Traumatic bone cyst*—it appears as round shaped with moderately defined outline. Needle aspiration is non-productive.
- *Adenomatoid odontogenic tumor*—radiolucency is associated with unerupted teeth. In mature stage, it appears as radiolucent with radiopaque foci.
- *Surgical defect*—patients give history of surgery.
- *Odontogenic myxoma*—in myxoma, mandible is more commonly affected. It shows a typical honeycomb pattern.
- *Anatomical variation*—in some cases, prominent incisive fossa can get confused with globulomaxillary cyst. But location of incisive fossa is in anterior region between central incisors.

Why Discarded and Updated Term

As the study by embryologist shows that there is no process or bony primordia are separated by epithelium. So there is no chance of entrapment of epithelium in this location so use of term globulomaxillary cyst is discarded. Nowadays any cyst in that location will be either radicular cyst from nonvital lateral incisor, or odontogenic keratocyst or adenomatoid odontogenic cyst.

Median Mandibular Cyst

The median mandibular developmental cyst is an extremely rare lesion occurring in the midline of the mandible. It is of questionable existence.

Origin

- *Fissural cyst*—some authors consider it as a true developmental cyst originating from proliferation of epithelial remnants entrapped in the median mandibular fissure during fusion of bilateral mandibular arches. But, as mandible is single bilobed proliferation of mesenchyma with central isthmus, there is no fusion of epithelium line process occurs, so entrapment of epithelium will not occur. So this theory is not possible for the development of median mandibular cyst.
- *Odontogenic origin*—nowadays, it appears that this entity, is a variant of lateral periodontal cyst or odontogenic keratocyst.

Clinical Features

- *Site*—it has got predilection for the inferior part of the mandible, in the central incisor region.
- *Symptoms*—most are clinically asymptomatic and are discovered only during routine radiographic examination.

- **Signs**—they seldom produce obvious expansion of the cortical plate of bone.
- **Teeth**—associated teeth react normally to pulp vitality test.

Radiographic Features

- **Appearance**—it is unilocular, well-circumscribed radiolucency, although it appears multilocular.
- **Shape**—the image is well defined, round or ovoid radiolucency that may be regular or irregular in shape.
- **Lamina dura**—the lamina dura around the lower incisor teeth is intact.
- **Teeth**—as it expands, it diverges the roots of the mandibular incisors.

Why Discarded

This cyst is discarded as there is no possibility to have epithelial entrapment during embryonic fusion in mandible.

Median Palatine Cyst

It is rare fissural cyst that developed due to entrapment of epithelium in line of fusion of lateral palatal shelves of maxilla. It is very difficult to distinguish from the nasopalatine cyst. Nowadays it is known as posterior extension of incisive canal cyst.

Clinical Features

- **Site**—it is very rare and develops in the midline of the hard palate posterior to pre-maxilla.
- **Symptoms**—patient notices the swelling in the midline of palate posterior to palatine papilla. It is usually asymptomatic but some patients may complain of pain.
- **Signs**—it is fluctuant and non-tender. Overlying mucosa is normal. Corticated plate may be perforated as the cyst grows. Expansion is rare in this cyst.
- **Teeth**—maxillary teeth are vital and aspiration produces amber colored fluid.
- If floor of nasal fossa is eroded, cyst may be superiorly displaced.

Radiographic Features

- **Site**—radiolucent lesion is behind the incisive canal in premolarmolar area.
- **Margins**—well-defined borders which are hyperostotic.
- **Appearance**—nasal septum image crosses the septum and appears on occlusal radiographs.
- **Teeth**—in some cases, divergence of teeth may occur.

Differential Diagnosis

- **Radicular cyst**—vitality test and periapical radiographs demonstrate intact lamina dura and normal periodontal ligament space in median palatine cyst.
- **Palatal space abscess**—soft, fluctuant swelling and yield pus on aspiration and non-vital teeth found adjacent to it which give rise to infection.
- **Incisive canal cyst**—it occurs in canal above palatine papillae while midpalatine cyst occurs in midline of palate posterior to palate.
- **Retention phenomenon**—seen laterally and not in midline. Aspiration would not yield amber colored fluid but viscous clear sticky liquid.
- **Malignant and benign tumors of salivary gland**—laterally and not in midline.

Why Discarded

This cyst is nowadays thought to be posterior extension of nasopalatine cyst.

Adenomatoid Odontogenic Tumor

It is also called 'Adenoameloblastoma' or 'ameloblastic adenomatoid tumor'. It is tumor of odontogenic epithelium with a duct-like structure and varying degrees of inductive changes in the connective tissue. The tumor may be partly cystic and in some cases the solid lesion may be present only as masses in the wall of a large cyst. A well-circumscribed lesion derived from odontogenic epithelium that usually occurs around the crowns of unerupted anterior teeth of young patients and consists of epithelium in swirls and ductal patterns interspersed with spherical calcifications.

Origin

- **Dental epithelium**—the close resemblance of the columnar cells to ameloblasts and the frequent association of the tumor with unerupted teeth indicate its origin from dental epithelium.

Types

- Peripheral adenomatoid odontogenic tumor
- Central adenomatoid odontogenic tumor
 - **Follicular type**—it is associated with embedded tooth
 - **Extrafollicular type**—it is not associated with embedded tooth.

Clinical Features

- **Incidence**—it represents 3% of odontogenic tumors and is a developmental outgrowth of odontogenic tissue.

Fig. 51-4: Swelling seen in anterior maxillary region due to adenomatoid odontogenic tumor or cyst.

- *Age and sex distribution*—it is found in individuals ranging from 5 to 50 years with 70% occurrence in 2nd decade with an average age of 16 years. Females are affected more than males in a ratio of 2:1.
- *Site*—it occurs more commonly in the maxilla than in the mandible, usually in the anterior region and especially in the cuspid area (**Fig. 51-4**). It is commonly associated with an unerupted tooth.
- *Symptoms*—commonly presented as an area of swelling over an unerupted tooth which is asymptomatic. Sometimes, it may expand cortical bone but is not invasive.
- *Signs*—it is frequently associated with an unerupted tooth in which the epithelial proliferation is confined within a connective tissue capsule that is attached to the tooth in a manner similar to the attachment of a dentigerous cyst. When the tumor occurs independently of unerupted teeth, it is often encapsulated. The tumor causes expansion of bone and fluctuation may be elicited.
- *Progress*—it is slow growing and is a gradually increasing painless swelling leading to asymmetry, frequently associated with missing teeth.
- *Extraosseous tumor*—very uncommonly, it develops extraosseously usually in the gingiva.

Radiographic Features

- *Radiodensity*—well-demarcated mixed radiolucent or opaque lesion.
- *Site*—tumor surrounds the entire tooth, most often canine in the maxilla. Radiolucency usually extends apically beyond the cemento-enamel junction.
- *Margin*—it may or may not be well circumscribed. Borders are sclerotic.
- *Internal structure*—unilocular radiolucency but may contain faint to dense radiopaque foci which may be seen peripherally as the lesion matures (**Fig. 51-5**). Dense cluster of radiopacities appear as 'small pebbles'.

Fig. 51-5: Radiolucency showing calcification in it may be due to AOT or AOC.

- *Target appearance*—there is a radiolucent circumferential halo which envelops a dense, central and round radiodense mass.
- *Effect on surrounding structure*—separation of roots or displacement of an adjacent tooth occurs frequently. There is also cortical expansion and root resorption. The lesion may inhibit the eruption of involved tooth (**Fig. 51-6**).

Fig. 51-6: CT scan of AOT or AOC showing lesion with impacted tooth in maxilla (Courtesy Dr Iswar).

Differential Diagnosis

- *Dentigerous cyst*—it is seen in 2nd to 4th decade as compared to adenomatoid odontogenic tumor which is seen in young age. It is seen in posterior region as

compared to adenomatoid odontogenic tumor which is seen in anterior region. Adenomatoid odontogenic tumor has tendency to surround more than just crown of the unerupted tooth.

- *Ameloblastoma*—it is more common in older age and posterior region. It is multilocular.
- *Ameloblastic fibroma*—it is seen in premolar-molar region and is multilocular.
- *Ameloblastic fibro-odontoma*—it is multilocular and radiopacities of enamel and dentin are seen inside the radiolucency as compared to adenomatoid odontogenic tumor where snowflakes are seen at the periphery.
- *Calcifying odontogenic cyst*—it occurs in older age as compared to adenomatoid odontogenic tumor and mandibular premolar area is mostly affected.
- *Odontogenic fibroma or myxoma*—tennis racket pattern is seen.

Why Discarded and Updated Term

Today we call this tumor as an adenomatoid odontogenic cyst. The reason for this is that after close inspection of the cyst's it seems proliferation which fills the lumen emerges from the epithelial lining. The calcification present in this cyst is identified as dentinoid material which derived from root sheath epithelium to induce root dentin. So due to all these factors more appropriate term for adenomatoid odontogenic tumor will be adenomatoid odontogenic cyst.

Cementoma

It is a true neoplasm of functional cementoblasts, which forms large masses of cementum or cementum-like tissue on the tooth root.

Clinical Features

- *Age and sex*—it occurs most frequently under the age of 25 years and with no significant sex predilection.
- *Site*—mandible is affected three times more frequently than the maxilla. Mandibular first molar is the most frequently affected tooth (**Fig. 51-7**); other involved teeth are the mandibular second and third molars.
- *Symptoms*—associated tooth is vital unless coincidentally involved. In some cases, pain may be there.
- *Sign*—lesion is slow growing and may cause expansion of cortical plates of bone. Periapical cementomas are multiple.

Radiographic Features

- *Appearance*—there is an area of increased density surrounded by the dark line of the fibrous capsule and with a thin white line of the adjacent cortical layer of the bone.

Fig. 51-7: Cementoma presenting as radiopaque structure in relation with lower left first molar.

Why Discarded and Updated Term

Nowadays this disease is recognized as periapical cemento-osseous dysplasia. This is disorganized product of bone periodontal membrane cementum complex.

True Cementoma

Earlier students were told the true cementoma represents benign proliferation of cementoblasts present in roots of premolar and molar teeth.

Why Discarded and Updated Term

Nowadays, this disease is recognized as cementoblastoma which is slow growing neoplastic proliferation of cementoblasts.

Gigantiform Cementoma

This is rare case of large round radiopaque mass seen in jaws.

Why Discarded and Updated Term

Nowadays this disease is recognized as ossifying fibroma. The reason for this is that these lesions are usually large ossifying fibroma with mature ossification.

Reparative Giant Cell Granuloma

It occurs in young persons usually before the age of 20 years. It is most often seen anterior to the first permanent molar. Most of the lesions are single, but more than one lesion can be seen. Spontaneous regression can be seen in reparative granuloma.

Size of the lesion varies greatly from a very small localized area of bone destruction, to one involving greater part of the bone. The margins may be poorly defined, so that exact limits of the lesion are unclear and indefinite. There is no cortex at the periphery of the lesion, as seen with the cyst. The outer and inner cortical plate of bone may become involved in the extension of the tumor and become destroyed, but the periosteum usually lays down a bony covering. The jaw is said to be expanded by the tumor. There is undulating or irregular bony covering.

Why Discarded and Updated Term

Nowadays, this is called central giant cell tumor. The reason for this is that the process which occurs in this disease is destructive rather than reparative. Second reason is that it is not a granuloma but proliferative reaction.

Aneurysmal Bone Cyst

It is an uncommon hemorrhagic lesion of the bone which is rarely seen in the jaw. It was first described as a clinicopathological entity by Jaffe and Lichtenstein in 1942. It is most often categorized as to be a tumor-like reactive lesion of bone. The name of this entity is misleading, in that, it does not contain vascular aneurysms and it is not a true bony cyst.

It represents an exaggerated localized proliferative response of the vascular tissue. It may be similar to peripheral and central giant cell granuloma to which it resembles in some ways including the histological presence of giant cells.

Pathogenesis

- *Local alteration in hemodynamics*—persistent local alteration in hemodynamics leads to increased venous pressure and development of dilated and engorged vessels in transformed bone area. Resorption of bone occurs, to which giant cells are related and this is replaced by connective tissue, osteoid and new bone.
- *Repair of hematoma of bone*—exuberant attempt at repair of hematoma of bone, similar to that of central giant cell granuloma. But, in the case of aneurysmal bone cyst, it is postulated that hematoma maintains a circulating connection with the damaged vessel. This would lead

to a slower flow of blood through the lesion and account for a clinical “welling” of blood. This is the only difference between the aneurysmal cyst and the giant cell granuloma that is in later lesion, the blood vessels fail to retain circulating connection with lesion.

- *Hemodynamic force*—Biesecker and his associates have proposed a new hypothesis for etiology and pathogenesis of this lesion that a primary lesion of the bone initiates an arteriovenous fistula and thereby creates, via its hemodynamic forces, a secondary reactive lesion of the bone. Thus occurrence of this cyst is secondary in association with osseous lesions like non-osteogenic fibroma, benign osteoblastoma and hemangioma of bone.

Clinical Features

- *Age*—although it may be seen in adults, it is more commonly seen as abnormalities of older children and adolescents with more than 90% of lesions occurring in individuals younger than the age of 30 years.
- *Sex*—it is more common in females than in males.
- *Site*—it usually involves the mandibular molar region as compared to anterior region.
- *History*—history of traumatic injury and of recent displacement of teeth which remain vital.
- *Symptoms*—aneurysmal cyst of the jaw produces a firm swelling which may be painful and tender on motion. Swelling becomes progressively worse and the rate of development is often described as rapid. Sometimes, patient may complain of difficulty in opening the mouth when there is impingement of the lesion on the capsule of TMJ.
- *Signs*—usually there is tilting or bodily displacement of teeth in the affected areas though it does not devitalize the affected tooth. Excessive bleeding may occur. When the lesion perforates the cortex and is covered by periosteum or only a thin shell of bone, it may exhibit springiness or egg-shell crackling, but it is not pulsatile. Bruit is not heard.

Radiographic Features

- *Radiodensity*—the aneurysmal bone cyst is an expansile osteolytic process within the affected bone and is projected as a definite radiolucency.
- *Internal structure*—invariably, fine septa are seen crossing through the lesion in a random pattern.
- *Appearance*—the term ‘soap bubble’ may be applied to describe an occasional multilocular radiographic appearance.
- *Margins*—are somewhat less regular and distinct than odontogenic cyst but more discrete than a central malignancy.

- *Expansion*—as the cyst enlarges to more than a few centimeters in anterior-posterior dimension, it also produces expansion of the buccal and lingual cortical plates.
- *Teeth*—simple tilting and bodily displacement of erupted teeth. Some degree of external root resorption may be seen though it will not devitalize the tooth.
- *Cortex*—there is also buccal and lingual expansion of the cortex often marked and described as ballooning or blowing out.

Differential Diagnosis

- *Ameloblastoma*—it is more common in older age group and in the mandibular posterior region.
- *Giant cell granuloma*—more common in the anterior region.
- *Central hemangioma*—it is more common in the mandible and it shows profuse hemorrhage if aspirated. Bruit is heard in such lesion.
- *Multilocular cyst*—it is more common in the mandibular posterior region of jaw and also the borders of the lesion are well defined.
- *Odontogenic myxoma*—it is more frequently associated with congenitally missing or unerupted tooth. It shows a typical honeycomb appearance.
- *Cherubism*—it occurs in a younger age group and it is a bilateral lesion.
- *Metastatic tumor*—it occurs in older age group.
- *Giant cell lesion of hyperparathyroidism*—more common in the older age group. Serum shows high levels of alkaline phosphatase.

Why Discarded and Updated Term

Today we call this cyst as central giant cell tumor. The reason for this is that all the central giant tumors have venous pressure bleeding quality. ABC has macroscopic blood-filled spaces rather than microscopic spaces. The term aneurysmal is also false as blood-filled spaces contain fibroblasts rather than endothelium. It also lacks cystic lining so the term aneurysmal bone cyst is discarded.

Eagle Syndrome

In this syndrome there is neck pain associated with elongated calcified styloid process.

Why Discarded and Updated Term

Today we called this as part of DISH syndrome (diffuse intraosseous skeletal hypertrophy). Initially, it is thought

to be occurred due to calcification of stylohyoid ligament. But nowadays it is seen that there is actually ossification of stylohyoid ligament with mature bone. Also, there is evidence that maximum of intervertebral ligament are also ossified.

Hand-Schuller-Christain Disease, Letterer Siwe Disease, Eosinophilic Granuloma and Histiocytosis X

It is an inflammatory reticuloendothelioma condition with evidence suggesting that it may be reaction to some type of infection. There is pathological accumulation of histiocytes and eosinophilic leukocytes.

Why Discarded and Updated Term

Nowadays dominant histolytic cells identified as antigen processing Langerhans cells. So it is now called Langerhans cell histiocytosis (LCH). All the three diseases are now called separated clinical entity under the heading of Langerhans cell histiocytosis.

Neurilemmoma, Neurinoma and Neuro-lemmoma

The above terms are derived from Greek word: neuron meaning nerve and lemma means husk or covering.

Why Discarded and Updated Term

Today we called this as Schwannoma. The reason for this is that tumor consists of Schwann cells around the nerve and not the nerve fiber or nerve sheath. Also, there is only proliferation of Schwann cells and not the basal lamina or other component of the neurilemma.

Traumatic Bone Cyst

It is empty space seen in the bone and many times it is not related to trauma.

Why Discarded and Updated Term

Today we call this as idiopathic bone cavity. There is no epithelium present in this cavity so use of term traumatic bone cyst should be avoided.

Causes and Classifications

Classifications of Diseases

White Lesions

Variation in structure and appearance of normal mucosa

- Leukoedema
- Fordyce's granules
- Linea alba

White lesion with definite precancerous potential

- Leukoplakia
- Erythroplakia
- Tobacco keratosis, actinic keratosis
- Lesion associated with electrogalvanism
- Carcinoma *in situ*
- Verrucous carcinoma
- Lichen planus
- Lichenoid reaction
- Oral submucous fibrosis
- Dyskeratosis congenita
- Lupus erythematosus
- Acanthosis nigricans

White lesion without precancerous potential

- Traumatic keratosis
- Focal epithelial hyperplasia
- Psoriasis
- Geographic tongue
- Pachyonychia congenita
- White sponge nevus
- Hereditary benign epithelial dysplasia
- Stomatitis nicotina
- Hyperkeratosis palmoplantaris with gingival hyperkeratosis
- Darrier's disease
- Intraoral skin grafts
- Pseudoxanthoma elasticum
- Hyalinosi cutis et mucosae oris
- Oral condyloma acuminatum
- Hairy leukoplakia

Nonkeratotic white lesion

- White hairy tongue

- Burns –thermal, chemical, electrical
- Desquamative gingivitis
- Epidermolysis bullosa
- Pemphigus
- Benign mucous membrane pemphigoid (BMMP)
- Diphtheria
- Syphilitic mucus patches
- Acute necrotizing ulcerative gingivitis (ANUG)
- Koplik's spot of measles
- Candidiasis
- Median rhomboidal glossitis
- Verruca vulgaris

Precancerous Lesion and Condition

Precancerous lesion

- Leukoplakia
- Erythroplakia
- Palatal lesion associated with reverse smoking
- Verrucous hyperplasia
- Carcinoma *in situ*

Precancerous condition

- Oral submucous fibrosis
- Sideropenic anemia
- Erosive lichen planus
- Discoid lupus erythematosus
- Dyskeratosis congenita

Histological Classification of Cancer and Precancer of the Oral Mucosa—Histological typing of cancer and precancer (WHO 1997)

Carcinomas

- Squamous cell carcinoma
- Verrucous carcinoma
- Basaloid squamous cell carcinoma
- Adenoid squamous cell carcinoma
- Spindle cell carcinoma
- Adenosquamous carcinoma
- Undifferentiated carcinoma

Benign lesions capable of microscopically resembling oral squamous cell carcinoma and oral verrucous carcinoma

- Papillary hyperplasia
- Granular cell tumor
- Discoid lupus erythematosus
- Median rhomboid glossitis
- Keratoacanthoma
- Necrotizing sialometaplasia
- Juxtaoral organ of Chievitz
- Chronic hyperplastic candidiasis
- Verruciform xanthoma
- Verruca vulgaris
- Condyloma acuminatum

Precancerous lesions (Clinical Classification)

- Leukoplakia
- Erythroplakia
- Palatal keratosis associated with reverse smoking

Precancerous lesions (Histological Classification)

- Squamous epithelial dysplasia
- Squamous cell carcinoma *in situ*
- Solar keratosis

Benign lesions capable of resembling oral precancerous lesions

- White lesions resembling leukoplakia
- Red lesions resembling erythroplakia
- Focal epithelial hyperplasia
- Reactive and regenerative atypia

Precancerous conditions

- Sideropenic dysphagia
- Lichen planus
- Oral submucous fibrosis
- Syphilis
- Discoid lupus erythematosus
- Xeroderma pigmentosum
- Epidermolysis bullosa

Red Lesion of Oral Mucosa**Inflammatory condition****Inflammation associated with traumatic injury**

- *Mechanical*—cheek biting, ill fitting denture, sharp edge, overhanging restoration and ecchymoses due to trauma.
- *Chemical*—aspirin, formocresol and TCA.
- *Thermal*—hot food, hot beverage and hot instrumentation.
- *Radiation*—mucositis, cheilitis.

Infection**Bacterial**

- Scarlet fever (red fever)
- Gonococcal stomatitis
- Vincent infection or gingivostomatitis
- Acute pharyngitis, tonsillitis

Fungal

- Atrophic candidiasis
- Angular cheilitis
- Acute pseudomembranous candidiasis

Viral

- Measles—Koplik's spot
- Lymphnodular pharyngitis
- Herpes simplex infection
- Herpes zoster
- Herpangina
- Chickenpox
- Hand-foot-mouth disease

Allergic/Immunological

- Pyogenic granuloma
- Giant cell epulis
- Pregnancy tumor
- Traumatic hemangioma
- Inflammatory fibrous hyperplasia
- Desquamative gingivitis

Congenital-hereditary developmental condition

- Hemangioma
- Sturge-Weber syndrome
- Rendu-Osler-Weber disease
- Hereditary hemorrhage telangiectasia
- Median rhomboidal glossitis
- Geographic tongue
- Melkersson-Rosenthal syndrome
- Crohn's disease

Vascular disease and blood disorder

- Purpura
- Polycythemia
- Agranulocytosis
- Polyarteritis nodosa
- Leukemia

Dermatological

- Pemphigus
- Erythema multiforme
- Stevens Johnson
- Lichen planus
- Lichenoid reaction
- Epidermolysis bullosa
- Psoriasis
- Lupus erythematosus

Other systemic disease

- Uremic stomatitis
- Diabetes stomatitis
- Scurvy
- Pernicious anemia
- Ulcerative stomatitis

Premalignant and malignant lesion

- Atrophic leukoplakia
- Erythroplakia
- Squamous cell carcinoma
- Carcinoma *in situ*
- Kaposi's sarcoma
- Hemangioendothelioma

Vesiculobullous Lesions**1st Classification***Hereditary*

- Epidermolysis bullosa
- Familial benign chronic pemphigus
- Dyskeratosis congenita
- Acrodermatitis enteropathica

Viral infection

- Primary herpetic gingivostomatitis
- Secondary herpetic gingivostomatitis
- Varicella (chickenpox)
- Shingles (herpes zoster)
- Measles
- Hand-foot-mouth disease
- Small pox and cat-scratch disease
- Infectious mononucleosis
- Herpangina
- Acute lymphnodular pharyngitis
- AIDS

Mucocutaneous diseases

- Pemphigus vulgaris
- Pemphigus vegetans
- Benign mucous membrane pemphigoid
- Bullous pemphigoid
- Lichen planus
- Toxic epidermal necrolysis

Miscellaneous

- Oral submucous fibrosis
- Hyperacidity or gastritis
- Constipation and malabsorption syndrome
- Impetigo
- Oral blood blister
- Erythema multiforme

2nd Classifications*Vesicular lesion**Non-febrile lesion*

- Recurrent herpes labialis
- Recurrent herpes stomatitis
- Reiter's syndrome
- Contact stomatitis
- Impetigo
- Dyskeratosis congenita

Febrile lesion

- Herpetic gingivostomatitis
- Herpangina
- Hand-foot-mouth disease
- Chickenpox
- Herpes zoster
- Smallpox

Bullous lesion

- Pemphigus
- Familial benign chronic pemphigus
- Bullous pemphigoid
- Benign mucous membrane pemphigoid
- Epidermolysis bullosa
- Dermatitis herpetiformis

- Erythema multiforme
- Stevens-Johnson syndrome

Cysts of the Oral Cavity*Odontogenic**Developmental*

- Primordial cyst
- Odontogenic keratocyst
- Gingival cyst of infant
- Gingival cyst of adult
- Lateral periodontal cyst
- Dentigerous cyst
- Eruption cyst
- Calcifying epithelial odontogenic cyst

Inflammatory

- Radicular cyst
- Periodontal cyst
- Inflammatory collateral cyst
- Paradental cyst

Non-odontogenic

- Nasopalatine cyst
- Median palatine cyst
- Median alveolar cyst
- Median mandibular cyst
- Globulomaxillary cyst
- Nasolabial cyst
- Nasoalveolar cyst
- Simple bone cyst
- Hemorrhagic bone cyst

Cysts Associated with maxillary sinus

- Benign mucosal cyst of maxillary antrum
- Mucocele–mucus retention cyst
- Surgical ciliated cyst

Soft tissue cysts

- Dermoid
- Epidermoid
- Branchial
- Thyroglossal
- Anterior median lingual cyst
- Oral cyst with gastric epithelium
- Cystic hygroma
- Parasitic cyst, hydatid cyst, cysticercosis cellulosae

Cysts of the salivary gland

- Mucocele
- Ranula

Oral Manifestation of AIDS*Fungal infection*

- Candidiasis
- Histoplasmosis
- Toxoplasmosis
- Cryptococcosis
- Geotrichosis

- Mucormycosis
- Aspergillosis
- Actinomycosis

Bacterial

- HIV gingivitis
- HIV necrotizing gingivitis
- HIV periodontitis
- Sinusitis
- STD

Viral

- Herpes simplex
- Herpes zoster
- Hairy leukoplakia
- Verruca vulgaris
- Condyloma acuminatum
- Focal epithelial hyperplasia
- Cytomegalovirus infection

Neoplasm

- Kaposi's sarcoma
- Squamous cell carcinoma
- Non-Hodgkin's lymphoma

Neurological

- Trigeminal neuralgia
- Facial palsy
- AIDS dementia

Miscellaneous

- Recurrent aphthous stomatitis
- Erythema multiforme
- Lichenoid reaction
- Progressive necrotizing ulceration
- Toxic epidermal necrolysis

Odontogenic Tumor

1st Classification

Benign odontogenic tumor

Odontogenic epithelium without odontogenic ectomesenchyme

- Ameloblastoma
- Squamous odontogenic tumor
- Pindborg tumor
- Clear cell odontogenic tumor

Odontogenic epithelium with odontogenic ectomesenchyme with or without dental hard tissue formation

- Ameloblastic fibroma
- Ameloblastic fibro-odontoma
- Ameloblastic fibrodentinoma
- Odontoameloblastoma
- Adenomatoid odontogenic tumor
- Complex and compound odontome

Odontogenic ectomesenchyme with or without included odontogenic epithelium

- Odontogenic fibroma
- Odontogenic myxoma
- Benign cementoblastoma

Malignant odontogenic tumor

Odontogenic carcinoma

- Malignant ameloblastoma
- Primary intraosseous carcinoma
- Malignant variant of other odontogenic epithelial tumor
- Malignant changes in odontogenic cyst

Odontogenic sarcoma

- Ameloblastic fibrosarcoma
- Ameloblastic dentinosarcoma

2nd Classification

Benign

Epithelial

- *With inductive changes in the connective tissue*
 - AOT
 - Ameloblastic fibroma
 - Dentinoma
 - Calcifying odontogenic tumor
 - Odontoameloblastoma
 - Odontoma
- *Without inductive changes in connective tissue*
 - Ameloblastoma
 - CEOT
 - Epithelial atypia
 - Ameloblastic changes in odontogenic cyst

Mesenchymal

- Odontogenic myxoma
- Odontogenic fibroma
- Cementoma
- Periapical cemental dysplasia
- Cementifying fibroma
- Benign cementoblastoma

Malignant

Epithelial

- *With inductive changes in connective tissue*
 - Ameloblastic fibrosarcoma
 - Ameloblastic odontosarcoma
- *Without inductive changes in connective tissue*
 - Malignant ameloblastoma
 - Primary intraosseous carcinoma
 - Malignant changes in odontogenic cyst

Benign Tumors of the Jaw

Odontogenic tumors

Epithelial

- Ameloblastoma
- Adenoameloblastoma
- Enameloma
- Pindborg tumor (CEOT)

Mesenchymal

- Dentinoma
- Cementoma
- Cementoblastoma

Mixed

- Ameloblastic fibroma
- Ameloblastic fibro-odontoma
- Ameloblastic odontoma

- Odontogenic myxoma
- Compound composite odontoma
- Complex composite odontoma
- Odontogenic fibroma

Developmental

- Dense invaginatus or dilated odontome
- Dense evaginatus

Non-odontogenic tumors

Epithelial tissue

- Papilloma
- Keratoacanthoma
- Adenoma

Fibrous connective tissue

- Fibroma
- Myxoma
- Fibrous hyperplasia
- Fibrous epulis
- Fibrous histiocytoma

Cartilage

- Chondroma
- Chondroblastoma
- Chondromyxoid fibroma

Adipose tissue

- Lipoma

Bone

- Osteoma
- Osteoid osteoma
- Osteoblastoma
- Exostosis and tori- torus palatinus, torus mandibularis
- Enostosis

Vascular tissue

- Hemangioma
- Lymphangioma
- Glomus tumor
- Hemangiopericytoma

Neural tissue

- Neurofibroma
- Neurilemmoma
- Schwannoma
- Ganglioneuroma
- Traumatic neuroma
- Melanotic neuroectodermal tumor of infancy

Muscle

- Leiomyoma
- Rhabdomyoma
- Myoblastoma

Giant cell tumors

- Central and peripheral giant cell tumor
- Giant cell granuloma
- Giant cell reparative granuloma
- Giant cell tumor of hyperthyroidism

Teratoma

Salivary gland tumors

- Adenoma

- Oncocytoma
- Oxyphilic adenoma
- Warthin's tumor
- Pleomorphic adenoma

Classification of Tumor

	<i>Tissue of origin</i>	<i>Benign</i>	<i>Malignant</i>
Epithelial tumors	Squamous epithelium	Squamous cell papilloma	Squamous cell carcinoma
	Transitional epithelial	Transitional cell papilloma	Transitional cell carcinoma
	Glandular epithelium	Adenoma	Adenocarcinoma
	Basal cell layer	—	Basal cell carcinoma
	Neuroectodermal	Nevus	Melanoma
	Hepatocyte	Liver cell adenoma	Hepatocellular carcinoma
Mesenchymal	Adipose tissue	Lipoma	Liposarcoma
	Adult fibrous tissue	Fibroma	Fibrosarcoma
	Embryonic fibrous tissue	Myxoma	Myxosarcoma
	Cartilage	Chondroma	Chondrosarcoma
	Bone	Osteoma	Osteosarcoma
	Synovium	Benign synovioma	Synovial sarcoma
	Skeletal muscle	Rhabdomyoma	Rhabdomyosarcoma
	Smooth muscle	Leiomyoma	Leiomyosarcoma
	Mesothelium		Mesothelioma
	Blood vessels	Hemangioma	Angiosarcoma
	Lymph vessels	Lymphangioma	Lymphangiosarcoma
	Glomus cell	Glomus tumor	
	Meninges	Meningioma	Invasive meningioma
	Hemopoietic cell		Leukemia
	Lymphoid tissue		Malignant lymphoma
	Nerve sheath	Neurilemmoma	Neurogenic sarcoma
	Nerve cell	Ganglioneuroma	Neuroblastoma
Mixed tumors	Salivary gland	Pleomorphic adenoma	Malignant salivary gland tumor
Tumor of more than one germ cell layer	Totipotent cells in gonads or in embryonal rests	Mature teratoma	Immature teratoma

Malignant Tumor of the Jaw

Odontogenic tumor

- Ameloblastic sarcoma and Fibrosarcoma
- Odontogenic sarcoma
- Carcinoma in odontogenic cyst

Non-odontogenic tumor

Epithelial

- Squamous cell carcinoma
- Mucoepidermoid carcinoma
- Adenocarcinoma
- Basal cell carcinoma
- Transitional cell carcinoma
- Melanoma
- Verrucous carcinoma
- Intraepidermoid carcinoma

Fibrous connective tissue

- Fibrosarcoma

Adipose tissue

- Liposarcoma

Cartilage

- Chondrosarcoma

Bone

- Osteosarcoma
- Osteochondrosarcoma

Vascular

- Hemangioendothelioma

Neural tissue

- Neurosarcoma
- Neurofibrosarcoma

Muscle

- Leiomyosarcoma
- Rhabdomyosarcoma

Lymphoid tissue

- Hodgkin and non-Hodgkin lymphoma
- Lymphosarcoma
- Reticular cell sarcoma
- Ewing sarcoma
- Burkitt's lymphoma
- Multiple myeloma
- Leukemia

Tumor of salivary gland

- Mucoepidermoid carcinoma
- Adenocystic carcinoma
- Adenocarcinoma
- Acinic cell carcinoma
- Malignant change in pleomorphic adenoma

Granulomatous Diseases**Specific or infective type**

- Syphilis
- Yaws and Bejel
- Tuberculosis
- Leprosy
- Melkersson Rosenthal syndrome
- Heerfordt's syndrome
- Blastomycosis
- Coccidioidomycosis
- Cryptococcosis
- Rhinosporidiosis
- Pyostomatitis vegetans
- Actinomycosis
- Candidiasis
- Aspergillosis
- Mucormycosis
- Lymphogranuloma venereum
- Granuloma inguinale

Non-specific

- Periapical granuloma
- Pyogenic granuloma
- Peripheral and central giant cell granuloma
- Foreign body granuloma
- Traumatic granuloma
- Crohn's disease
- Pulsating granuloma

Histiocytosis**Non-lipid**

- Eosinophilic granuloma
- Hand-Schüller-Christian disease
- Letterer-Siwe disease

Lipid

- Gaucher's disease
- Niemann-Pick disease

Malignant

- Wegener's granulomatosis
- Midline lethal granuloma
- Hodgkin's disease

Gingival Hyperplasia (Clinical Classification)**Localized**

- Marginal
- Papillary
- Discrete

Generalized

- Diffuse
- Marginal
- Papillary

Gingival Hyperplasia (Etiological Classification)**Inflammatory****Acute**

- Gingival or periodontal abscess
- Acute exacerbation of chronic inflammatory enlargement

Chronic**Local irritants**

- Calculus
- Food lodgment area
- Occlusal trauma
- Mouth breathing
- Overhanging restoration
- Foreign bodies
- Poor oral hygiene

Infection

- Bacterial
- Viral
- Fungal
- Fusospirochetal
- Parasitic
- Saprophytic

Allergy**Non-inflammatory**

- Familial or hereditary
- Developmental
- Congenital
- Idiopathic
- Drug induced
- Dilantin sodium
- Phenobarbitone
- Nifedipine
- Cyclosporine

Combined**Conditional**

- Hormonal (puberty and thyroid dysfunction)
- Leukemic enlargement—myelogenous or monocytic
- Polycythemia vera
- Vitamin C deficiency
- Non-specific conditional enlargement
 - Epulis—fibrous
 - Epulis fissuratum
 - Eosinophilic granuloma
 - Plasma cell granuloma

- Crohn's disease
- Peripheral giant cell granuloma
- Wegener's granulomatosis

Cyst

- Eruption
- Gingival

Neoplastic

Benign

- Fibroma
- Granular cell myoblastoma
- Papilloma
- Hemangioma
- Peripheral ameloblastoma
- Peripheral odontogenic fibroma

Malignant

- Squamous cell carcinoma
- Fibrosarcoma
- Reticular cell sarcoma
- Melanoma
- Malignant lymphoma
- Malignant hemangioendothelioma or hemangioendotheliosarcoma
- Metastasis from lung, colon, testis, kidney and cervix

Syndrome associated with gingival hyperplasia

- Rutherford
- Cannon's disease
- Cross
- Zimmermann-Laband
- Cowden's
- Papillon Lefevre
- Tuberous sclerosis
- Sturge-Weber
- Melkersson-Rosenthal

Oral Pigmentation

1st Classification

Exogenous

Occupational

- Lead industry—lead
- Match industry—phosphorus
- Fluorescent lamp industry—mercury
- Photography—silver

Habits

- Tobacco—in the form of smoking, chewing and snuff dipping
- Pan—catechu, pan and pan masala
- Food—food stuff, black berries, blue grapes, coloring agent of sweets and chocolates

Therapeutic

- Drugs—anti-malarial drugs and contraceptives
- Metallic salts—gold for tuberculosis, bismuth for diarrhea, silver for nasal drop, mercury for diuretic

Others

- Amalgam tattoos
- Other self made tattoos—graphite, methylene blue

- Black hairy tongue
- Poor oral hygiene

Hypopigmentation and de-pigmentation

- Albinism
- Vitiligo
- Pernicious anemia
- Hormonal disturbances
- Parasitic infection
- Chédiak-Higashi syndrome
- Tuberous sclerosis
- Cross syndrome
- Severe burns
- Extensive traumatic injury

Endogenous

Physiologic

- Ethnic, racial variation
- Physiologic melanotic macule and papule
- Fordyce's granules
- Postmenopausal changes in sex hormones
- Pregnancy

Pathological

- Addison's disease
- Acromegaly
- Peutz-Jeghers syndrome
- Lentigo
- Nevi (intradermal, compound, junctional, blue)
- Neurofibromatosis
- Metastatic carcinoma
- Malnutrition
- *Acanthosis nigricans*
- Cyanosis
- Hemolytic anemia
- Jaundice
- Hemochromatosis
- Hemosiderosis
- Porphyria
- Carotenemia
- Hematoma-ecchymoses-varicosities-purpura
- Niemann-Pick disease
- Diabetic melanosis
- Simmond's disease

2nd Classification

Benign melanocytic lesions

- Racial pigmentation
- Physiologic pigmentation
- Smoking associated pigmentation
- Ephelis
- Lentigo
- Oral melanotic macules
- Nevi
- Hematoma

Neoplastic conditions

- Melanoma
- Multiple neurofibromatosis
- Neuroectodermal tumor of infancy
- Hemangioma
- Kaposi's sarcoma

Different type of pigmentation and their features				
Condition	Appearance	History	Age	Frequency
Melanoplakia	Macule of varying size, shape and location of oral mucosa	No symptoms	Birth to 1 year	Common in dark race
Amalgam tattoo	Macule on gingiva or edentulous ridge	Amalgam filled teeth	5 years and older	Common
Petechiae and ecchymosis	Macule anywhere in oral cavity or skin	Recent trauma bleeding diathesis	Young children	Occasional
Melanotic macule	Small macule < 2 cm on lower lip gingiva or buccal mucosa	—	41-42 years	M/F 1:2.2
Superficial spreading melanoma	Enlarging macule on palate or maxillary sinus	Several years Slowly enlarging	Mean age 50.5	Rare M/F=2:1
Junctional nevus	Macule occurs anywhere in oral cavity		Mean age 38	Rare in oral cavity
Heavy metal poisoning	Macular lesion— free gingiva	Malaise anemia	Working age	Rare
Peutz-Jeghers syndrome	Macule around lip buccal mucosa, finger body orifice	Melanin intestinal polyposis	Distinct at puberty	Rare
Albright syndrome	Café au lait spot on skin and mucous membrane	Skeletal endocrine	—	—
Firm lesions Amalgam fragment	Macule on gingiva or edentulous ridge	Firm mass in tissue	5 years and older	Common
Late hematoma	Mass and swelling	Previous trauma	—	Occasional
Giant cell granuloma	Moderately firm macule and nodule on gingiva and alveolar	Slowly expanding	30 years and over	Occasional
Pigmented lesion	Papule nodule or polypoid mass usually on buccal mucosa	Present for some time	—	Occasional
Intramucosal nevus	Papule nodule or polypoid mass	Present from birth	—	Rare
Compound nevus	Same	Same	—	Same
Melanoma	Pigmented or amelanotic nodule polypoid mass on palate and maxillary gingiva	Rapidly enlarging	—	Rare M/F 2:1
Neuroectodermal tumor	Expansion of labial sulcus pigmented or pink	Slowly expanding mass in anterior maxilla	Birth to 1 year	Rare

Pigmentation due to exogenous deposits

- Amalgam tattoo
- V Graphite tattoo
- Heavy metal pigmentation
- Drug induce pigmentation

Miscellaneous condition

- Peutz-Jeghers syndrome
- Addison disease
- Pigmented *lichen planus*
- Hairy tongue
- Mucocele
- HIV-associate oral pigmentation
- Endocrinopathic pigmentation

Diseases of the Maxillary Sinus**Traumatic**

- Fracture of maxilla, nasal bone, zygoma and orbital floor
- Hematoma
- *Foreign bodies*—root piece, bullet injury, antroliths
- Oroantral fistula

Inflammatory

- Acute and chronic sinusitis
- Local hyperplasia from odontogenic infection
- Antral polyp
- Osteomyelitis

Cysts**Intrinsic**

- Mucus retention cyst (mucocele)
- Serous cyst
- Pseudo cyst

Extrinsic

- *Odontogenic*
 - Radicular
 - Dentigerous
 - Primordial
 - Keratocyst
- *Non-odontogenic*
 - Globulomaxillary
 - Traumatic
 - Aneurysmal bone cyst (ABC)

Neoplasm**Odontogenic**

- Ameloblastoma
- Adenoameloblastoma
- Calcifying Epithelial Odontogenic Tumor (CEOT)

Nonodontogenic

- Exostosis
- Enostosis

Malignant

- Squamous cell carcinoma
- Midline lethal granuloma*

Metabolic

- Fibrous dysplasia
- *Leontiasis ossea*

* It is controversial issue to consider midline lethal granuloma as a malignancy as many investigators in spite of taking repeated biopsies have not found neoplastic tissue in these lesions.

Sexually Transmitted Diseases

- Syphilis
- Yaws and Pinta
- Gonorrhea
- Genital herpes
- Genital warts
- Nonspecific genital infection
- Trichomoniasis
- *Pediculosis pubis*
- Scabies
- *Molluscum contagiosum*
- Chancroid
- Lymphogranuloma venereum
- Lymphogranuloma inguinale
- Hepatitis B
- Cytomegalovirus inclusion body
- Infectious mononucleosis
- AIDS

Sexually Transmitted and Blood Born Disease**Bacterial and chlamydial STD (potentially curable and rarely blood borne)**

- Gonorrhea and related clinical syndrome (urethritis, cervicitis, salpingitis, pelvic inflammatory disease, disseminated systemic infection, arthritis, proctitis, pharyngitis)
- Non- and post-gonococcal urethritis and related clinical syndrome (cystitis, epididymitis, Reiter's disease, pelvic inflammatory disease)
- Syphilis and other treponemal infection (yaws pinta bejel)
- Chancroid
- Granuloma inguinale
- Lymphogranuloma venereum
- Gay bowel syndrome associated pathogen

Viral STD (currently incurable some frequently blood born)

- Herpes simplex virus infection by HSV I and II
- Infectious mononucleosis
- Cytomegalovirus infection
- Viral hepatitis
 - Hepatitis A
 - Hepatitis B
 - Hepatitis D
 - Hepatitis C
 - Hepatitis E
 - Hepatitis F
- AIDS
- T cell lymphoma and leukemia
- *Molluscum contagiosum*

Miscellaneous bacterial fungal and parasitic infection which sometime manifested as STD (usually curable and rarely blood born except candida)

- Vulvovaginal candidiasis
- Trichomoniasis
- Vaginitis, cervicitis and cystitis
- Bacterial vaginosis
- Intestinal protozoa infection
- Ectoparasitic skin infection

Other blood born infection with no evidence of sexual transmission

- Toxoplasmosis
- Malaria
- Babesiosis
- Trypanosomiasis

Autoimmune Disorder**Associated with Mucocutaneous Lesion**

- Recurrent aphthous ulcer
- Behcet's disease
- Pemphigus
- Bullous pemphigoid
- Cicatricial pemphigoid
- Dermatitis herpetiformis

Salivary gland

- Mikulicz's disease
- Sjögren's syndrome

Blood disorder

- Pernicious anemia
- Purpura

Collagen disorder

- Systemic lupus erythematosus
- Scleroderma
- Rheumatic arthritis

Miscellaneous

- Myasthenia gravis
- Dermatomyositis
- Oral submucous fibrosis

Blood Disorders**Disorders of RBC****Deficiency**

- Iron deficiency anemia
- Pernicious anemia
- Normocytic anemia
- Aplastic anemia
- Hemolytic anemia

Extra-corporeal causes

- Infection and toxin
- Hypersplenism
- Rh factor incompatibility (hemolytic disease of newborn, erythroblastosis fetalis)
- Chronic liver disease
- Autoimmune diseases
- Transfusion reaction

Intra-corporeal causes

- Hereditary spherocytosis
- Sick cell anemia
- Thalassemia
- Cooley's anemia
- Glucose-6 phosphate dehydrogenase deficiency
- Pyruvate kinase deficiency
- Folic acid and B₁₂ deficiency

Polycythemia

- Relative
- Secondary
- Vera (malignant)

Disorders of WBC**Qualitative**

- Lazy leukocyte syndrome
- Chédiak-Higashi syndrome

Quantitative

- Agranulocytosis
- Cyclic neutropenia

- Myeloblastic leukemia
- Decrease of eosinophils

Disorders of platelet**Purpura**

- Idiopathic thrombocytopenic purpura
- Secondary thrombocytopenic purpura
- Thrombotic thrombocytopenia
- Drug-associated thrombocytopenia
- Thrombocytopathia
- Glanzmann's thrombasthenia
- von Willebrand's disease
- Bernard-Soulier syndrome
- Aldrich syndrome

Thrombocytosis**Disorders of coagulation**

- Hemophilia A
- Hemophilia B
- Factor XI deficiency
- Factor X deficiency
- von Willebrand's disease

Fibro-osseous Lesions**Lesions arising from periodontal ligament**

- Periapical cemental dysplasia
- Localized fibro-osseous cemental lesion
- Florid osseous dysplasia
- Ossifying fibroma
- Cementifying fibroma

Fibrous dysplasia

- Monostotic
- Polyostotic
- Familial

Fibro-osseous neoplasm of uncertain origin or debatable origin

- Cementoblastoma
- Osteoblastoma
- Osteoid osteoma
- Juvenile ossifying fibroma
- Fibro-osteoma or osteofibroma
- Cementifying fibroma
- Paget's disease
- Ossifying fibrous epulis

Giant cell lesion

- Central giant cell tumor or central giant cell reparative granuloma
- Brown tumor of hyperthyroidism
- Aneurysmal bone cyst
- Cherubism

Mucocutaneous Disorder**Genodermatoses**

- White sponge nevus

- Darrier's disease
- Peutz-Jeghers syndrome
- Dyskeratosis congenita
- Hereditary benign intraepithelial dyskeratosis
- *Pachyonychia congenita*
- Hyalinosis cutis et mucosa oris
- *Pseudoxanthoma elasticum*

Non-infective disease

Vesicular

- Erythema multiforme
- Pemphigus
- Benign mucous membrane pemphigoid
- Bullous pemphigoid
- Epidermolysis bullosa
- Bullous Lichen planus

Non-vesicular disease

- Lichen planus
- Benign migratory glossitis

Collagen disorder

- Lupus erythematosus
- Scleroderma
- *Polyarteritis nodosa*
- Vasculitis
- Ischemic lingual necrosis
- Wegner granulomatosis
- Midline lethal granuloma

Degenerative and relative disorder

- Amyloidosis
- Oral submucous fibrosis
- Senile solar elastosis

Pigmentation

- Racial pigmentation
- Endocrinopathy
- Addison disease
- Albert syndrome
- Bronze diabetes
- Anemia

Oral Hamartomas

Odontogenic

Those involving teeth

- Dens invaginatus
- Dens evaginatus
- Talon's cusp

Those not involving teeth

- Enameloma
- Odontoma
- Gigantiform cementoma
- Dental lamina cyst of newborn

Non-odontogenic

Epithelial origin

- Epstein pearls and Bohn's nodule

- Oral and labial melanotic macule
- Pigmented cellular nevus

Vascular origin

- Hemangioma
- Lymphangioma
- Glomus tumor

Osseous origin

- Torus palatinus
- Torus mandibularis

Adipose tissue

- Lipoblastomatosis

Neural tissue

- Neurofibromatosis

Unknown or doubtful origin

- Granular cell myoblastoma
- Congenital epulis of newborn
- Melanotic neuroectodermal tumor of infancy
- Fibromatosis gingivae

Disorders of the Salivary Glands

Developmental

- Congenital aplasia or agenesis
- Congenital hypoplasia
- Atresia
- Aberrance or ectopic gland
- Diverticuli
- Accessory duct
- Congenital fistula

Inflammatory

- *Acute and chronic*
 - Staphylococcus
 - Streptococcus
 - Actinomycosis
 - Tuberculosis
- *Viral infection*
 - Mumps
 - Cytomegalovirus inclusion disease
 - Para-influenza
- Sarcoidosis
- Melkersson-Rosenthal syndrome
- Heerfordt's syndrome
- Allergy
- Secondary to sialolithiasis
- Post-irradiation to oral tumor
- Salivary fistula

Sialolithiasis

- Due to stricture of the duct
- Due to trauma or infection
- Due to salivary stone calculi
- Mucus plug

Cysts

- Mucocele
- Ranula
- Lymphoepithelial cyst
- Branchial cyst

Frey's syndrome

Sialadenosis

- Non-inflammatory swelling of salivary gland

Sjögren's syndrome**Necrotizing sialometaplasia****Neoplasms****Benign epithelial**

- Adenoma
- Oncocytoma
- Warthin's tumor
- Pleomorphic adenoma

Malignant epithelial

- Adenocarcinoma
- Mucoepidermoid carcinoma
- Adenocystic carcinoma
- Acinic cell carcinoma
- Malignant pleomorphic adenoma

Mesenchymal benign

- Hemangioma
- Lymphangioma
- Neurofibroma
- Schwannoma
- Xanthoma
- Lipoma

Malignant mesenchymal

- Rhabdomyosarcoma
- Hemangioendothelioma

Others

- Lymphoma—Hodgkin and non-Hodgkin
- Metastatic

Oral Lymphoid Tissue Lesion**Developmental lesions**

- Reactive lymphoid aggregates
- Lymphoid hamartomas
- Angio-lymphoid hyperplasia with eosinophilia

Cystic

- Lymphoepithelial cyst

Neoplastic

- Benign—Warthin's tumor
- Malignant—lymphoepithelioma (epithelial) and malignant lymphoma, Burkitt's lymphoma, non-Hodgkin lymphoma and leukemia (connective tissue)

Syndrome

- Mikulicz's disease of syndrome
- Sjögren's syndrome

Disorders of the Temporomandibular Joint**Developmental**

- Agenesis of the condyle
- Hypoplasia of the condyle
- Hyperplasia of the condyle
- Exostosis of the joint

Traumatic

- Trauma to disc
- Trauma to developing condyle or growth center
- Trauma to ligament
- Subluxation or dislocation or dislocation within displacement
- Ankylosis
- Foreign body in the joint space
- Trauma to muscle

Inflammatory**Infective**

- Pyogenic infection from staphylococci
- Syphilis
- Tuberculosis
- Actinomycosis
- Rheumatic arthritis
- Osteomyelitis
- Psoriasis
- Secondary to hepatitis B infection

Non-infective

- Still's disease
- Systemic lupus erythematosus
- Ankylosis spondylitis
- Synovitis

Non-articular arthritis

- Myositis
- Myositis ossificans
- MPDS

Metabolic Disorders

- Gout
- Chondrocalcinosis
- Oxalosis
- Amyloidosis
- Wilson's disease
- Gaucher's disease

Neoplasms**Benign**

- Osteoma
- Chondroma
- Osteochondroma
- Fibromyxoma
- Synovioma

Malignant

- Osteosarcoma
- Chondrosarcoma
- Synovial sarcoma
- Malignant lymphoma

Neuropathic

- Charcoat joint
- Ritter's sympathetic dystrophy

Internal derangement

- Disc displacement
- Disc fracture

Giant Cell Disorders**Traumatic**

- Peripheral giant cell granuloma
- Central giant cell granuloma
- Traumatic granuloma
- Epulis fissuratum
- Pyogenic granuloma
- Internal resorption
- Periapical granuloma

Infection

- Tuberculosis
- Syphilis
- Leprosy
- Blastomycosis
- Sarcoidosis
- Histoplasmosis
- Candidiasis
- Aspergillosis
- Actinomycosis
- Cryptococcosis
- Mucormycosis
- Rhinosporidiosis
- Lymphogranuloma

Cystic

- ABC
- Traumatic bone cyst
- Calcifying epithelial odontogenic cyst (CEOC)

Metabolic

- Hyperparathyroidism
- Paget's disease
- Fibrous dysplasia
- Cherubism
- Histiocytosis

Neoplasms

- Giant cell tumor
- Osteoblastoma
- Osteosarcoma
- Malignant lymphomas
- Wegener's granulomatosis

- Midline lethal granuloma*
- Burkitt's lymphoma
- Reticular cell sarcoma
- Pseudosarcomatous fascitis

* It is controversial issue to consider midline lethal granuloma as a malignancy as many investigators in spite of taking repeated biopsies have not found neoplastic tissue in these lesions.

Enamel Pathology**Developmental**

- Amelogenesis imperfecta
- *Dens invaginatus*
- Enameloma

Environmental pathology

- Attrition
- Abrasion
- Erosion

Enamel caries

- Pit and fissure
- Smooth surface
- Caries at cemento-enamel junction

Pigmentation

- Endogenous
- Exogenous

Enameloma**Dentin Pathology****Developmental**

- Dentinogenesis imperfecta
- Dentinal dysplasia
- Regional odontodysplasia
- Dentin hypocalcification

Dentinal caries**Neoplastic**

- Dentinoma
- Odontoma

Regressive changes

- Secondary dentin
- Dentinal sclerosis

Verrucous-papillary Lesion**Reactive lesion**

- Papillary hyperplasia of palate
- Condyloma latum
- Squamous papilloma
- Oral warts
- Oral papillomatosis

- Condyloma acuminatum
- Heck's disease

Neoplasm

- Keratoacanthoma
- Verrucous carcinoma

Unknown Etiology

- Pyostomatitis vegetans
- Verruciform xanthoma

Disorders of Tongue

Developmental

- Aglossia or hypoglossia
- Ankyloglossia
- Bifid tongue
- Lingual polyp
- Macroglossia
- Midline fistula
- Teratoma
- Median rhomboid glossitis

Infectious

- Bacterial
- Fungal and saprophytic
- Parasitic
- Viral

Cystic

- Epidermoid
- Dermoid
- Lymphoepithelial
- Mucus
- Anterior median lingual cyst
- Gastric mucosal cyst
- Parasitic cyst
- Bronchogenic cyst

Neoplastic

Benign

- Fibroma
- Granular cell myoblastoma
- Glomus tumor
- Leiomyoma
- Rhabdomyoma
- Neurofibroma
- Keratoacanthoma
- Traumatic neuroma
- Papilloma
- Pyogenic granuloma
- Adenoma
- Hemangioma
- Lymphangioma

Malignant

- Squamous cell carcinoma

- Adenocarcinoma
- Transitional cell carcinoma
- Verrucous carcinoma
- Mucoepidermoid carcinoma
- Reticular cell carcinoma
- Lymphosarcoma
- Angiosarcoma
- Kaposi's sarcoma
- Melanoma
- Rhabdomyosarcoma

Metastatic lesions from

- Kidney
- Liver
- Stomach
- Lung

Red and white lesions

- Leukoplakia
- Erythroplakia
- Lichen planus
- Oral submucous fibrosis
- Candidiasis
- Psoriasis
- Focal epithelial hyperplasia
- White sponge nevus
- Pemphigus
- Syphilitic mucus patches
- Verruca vulgaris

Neurological

- Dyskinesia—involuntary movements
- Glossodynia
- Trigeminal neuralgia
- Glossopharyngeal neuralgia
- Polyneuritis
- Neurofibromatosis
- Tongue thrusting
- Dysgeusia

Papillary changes in tongue

Atrophic

- Median rhomboid glossitis
- Geographic tongue
- Pernicious anemia
- Protein deficiency
- Lichen planus
- Oral submucous fibrosis
- Scleroderma

Hypertrophic

- White and black hairy tongue
- After antibiotic therapy
- After steroid therapy
- Hydrogen peroxide mouthwash
- Immunosuppressive drugs
- Smoking
- High fever
- Constipation
- Hyperacidity

Fissured tongue

- Congenital
- Syphilis
- Amyloidosis
- Melkersson Rosenthal syndrome
- Papillon Lefevre syndrome
- Traumatic bite

Systemic diseases manifested in tongue

- Infection—bacterial, viral and fungal
- Blood disorders
- Metabolic disorders
- Dermatological disorders
- Collagen and autoimmune disorders

Calcification of Oral Soft Tissue**Lymph nodes**

- Chronic infection (tuberculosis)
- Calcification following necrosis
- Calcification in metastatic tumor

Sialoliths

- In submandibular gland
- In minor salivary gland

Antroliths

- In maxillary antrum

Calcified ligament

- Eagle's syndrome

Osteomas

- Osteoma cutis
- Osteoma of the tongue

Calcified blood vessels

- Arteriosclerosis of facial artery
- Sturge-Weber syndrome
- Phleboliths

Myositis ossificans

- Localized
- Progressive myositis ossificans

Cysticercosis

- Calcification of worm larvae

Neoplasms

- Ossifying fibroma
- Calcifying epithelial odontogenic cyst
- Calcifying epithelial odontogenic tumor
- Cementifying fibroma
- Calcifying fibroma

Miscellaneous

- Pulp calcification
- Hypervitaminosis
- Chronic osteomyelitis
- Systemic sclerosis
- Dystrophic calcification in areas of tissue necrosis

Vascular Tissue Disorders**Arteritis**

- Polyarteritis nodosa

Midfacial granuloma syndrome

- Wegner's granulomatosis
- Stewart type of midfacial granuloma
- Giant cell arteritis
- Radiation arteritis

Vascular hamartomas

- Hemangioma
- Lymphangioma

Telangiectasia

- Hereditary hemorrhagic telangiectasia
- Radiation telangiectasia

Vascular tumor

- Hemangioendothelioma
- Hemangiopericytoma
- Kaposi sarcoma
- Angiolymphoid hyperplasia with eosinophils
- Kimura's disease

Oral Ulcerative Lesions**According to duration****Acute**

- Acute herpetic stomatitis
- Acute aphthous stomatitis
- Erythema multiforme
- Allergy
- ANUG
- Herpes zoster
- Herpangina

Chronic

- Traumatic ulcer
- Tuberculosis ulcer
- Syphilitic ulcer
- Actinomycosis ulcer
- Erosive lichen planus
- Malignant ulcer

Recurrent

- Recurrent aphthous ulcer
- Recurrent herpetic stomatitis
- Cyclic neutropenia
- Allergic reaction
- Erosive lichen planus

- Ulcer due to nutritional deficiency
- Erythema multiforme

According to Etiology

Local trauma

- Trauma due to sharp and malposed teeth
- Trauma due to appliance or restoration
- Trauma due to epileptic seizure
- Trauma during whooping cough
- Trauma from injecting needle

Chemical irritant

- Local use of chemical agents like phenol, TCA, formocresol, eugenol, phosphorus
- Local use of caustic drugs

Thermal

- Hot foods (pizza burn)
- Hot instrument
- Reverse smoking
 - Cold ice, CO₂ snow or local anesthetic or ether spray
 - Actinic radiation

Infection

Viral

- Herpes simplex
- Herpes zoster
- Chickenpox
- Smallpox
- Measles
- Rubella
- Hand foot and mouth disease
- Herpangina
- Acute lymphonodular pharyngitis
- Infectious mononucleosis
- AIDS

Bacterial

- Tuberculosis
- Syphilis
- ANUG
- Scarlet fever
- Diphtheria

Fungal infection

- Candidiasis
- Histoplasmosis
- Blastomycosis
- Mucormycosis
- Cryptococcosis

Allergy

- Local (stomatitis venenata)
- Systemic (stomatitis medicamentosa)

Neoplastic

- Squamous cell carcinoma
- Mucoepidermoid carcinoma
- Basal cell carcinoma
- Melanoma
- Malignant lymphoma

Systemic

Blood disorders

- Agranulocytosis
- Cyclic neutropenia
- Polycythemia
- Leukemia
- Aplastic anemia

Nutritional deficiency

- Vitamin B complex
- Protein deficiency
- Diabetes mellitus
- Uremia
- Metal poisoning
- Xerostomia
 - Gastric hyperacidity or peptic ulcer
- Constipation or malabsorption syndrome
- Histiocytosis-X

Disease of unknown origin

- Aphthous ulcer
- Erythema multiforme
- Epidermolysis bullosa
- Systemic lupus erythematosus
- Lichen planus
- Pemphigus
- BMMP
- Acrodermatitis enteropathica

Syndrome

- Stevens-Johnson
- Behcet's
- Reiter's

Disorders of Teeth (WHO)

Abnormalities of size and form

- Concrescence
- Fusion
- Gemination
- *Dens evaginatus*
- *Dens in dente*
- *Dens invaginatus*
- Enamel pearls
- Peg shaped
- Taurodontism
- Tuberculum paramolar
- Macrodonia
- Microdonia

Mottled teeth

- Dental fluorosis
- Mottling of enamel
- Non-fluoride enamel opacity

Disturbances in tooth formation

- Aplasia and hypoplasia of cementum

- Dilaceration of tooth
- Enamel hypoplasia (neonatal, postnatal, prenatal)
- Regional odontodysplasia (Turner tooth)

Hereditary disturbance in tooth structure

- Amelogenesis imperfecta
- Dentinogenesis imperfecta
- Odontogenesis imperfecta
- Dentinal dysplasia shell teeth

Disturbances in tooth eruption

- Dentia praecox
- Natal teeth
- Neonatal teeth
- Premature eruption of tooth
- Premature shedding of primary tooth
- Retained primary teeth

Supernumerary teeth

- Distomolar
- Fourth molar
- Mesiodens
- Paramolar
- Supplementary teeth

Anodontia

- Hypodontia
- Oligodontia

Other developmental disorders

- Embedded teeth
- Impacted teeth
- Teething syndrome
- Color change during tooth formation

Causes

Teeth Pathology

Hyperdontia

- Idiopathic
- Cleft lip and cleft palate
- Gardner's syndrome
- Cleidocranial dysplasia

Hypodontia

- Idiopathic
- Cleft lip and palate
- Hereditary hypohidrotic ectodermal dysplasia
- Incontinentia pigmenti
- Radiotherapy during childhood

Macrodontia

- Idiopathic
- Fusion
- Gemination
- Facial hemihyperplasia
- Gigantism

Microdontia

- Supernumerary teeth
- Idiopathic
- Peg shaped lateral
- Cleft lip and palate
- Hereditary hypohidrotic ectodermal dysplasia
- Radiotherapy during childhood
- Hypopituitarism

Malformed crown

- Mesiodens
- Enamel hypoplasia
- Peg shaped lateral incisor
- Turner tooth
- Talon cusp
- Amelogenesis imperfecta
- Dens evaginatus
- Dentinogenesis imperfecta
- Regional odontodysplasia
- Congenital syphilis
- Vitamin D resistant rickets
- Renal osteodystrophy
- Hypoparathyroidism
- Epidermolysis bullosa
- Radiotherapy during childhood

Enamel loss

- Caries
- Attrition
- Abrasion
- Erosion
- Amelogenesis imperfecta
- Dentinogenesis imperfecta

Extrinsic stain

- Tobacco
- Coffee, tea
- Cold drink
- Chromogenic bacteria

Intrinsic discoloration

- Aging
- Death of pulp
- Fluorosis
- Tetracycline
- Internal resorption
- Calcific metamorphoses
- Dentinogenesis imperfecta
- Amelogenesis imperfecta
- Congenital erythropoietic porphyria
- Erythroblastosis fetalis

Abnormal shaped root

- External root resorption
- Dilaceration
- Hypercementosis
- Supernumerary roots
- Concrescence

- Taurodontism
- Enamel pearl
- Benign cementoblastoma
- Radiotherapy during childhood
- Dentinogenesis imperfecta
- Dentin dysplasia type I

Enlarged pulp chamber

- Internal resorption
- Taurodontism
- Dentinogenesis imperfecta
- Regional odontodysplasia
- Vitamin D resistant rickets
- Hypophosphatasia
- Dentin dysplasia type II

Pulpal calcification

- Idiopathic pulp stone
- Secondary dentin
- Calcific metamorphosis
- Dentinogenesis imperfecta
- Dentin dysplasia type I
- Dentin dysplasia type II

Early exfoliation

- Trauma
- Aggressive periodontitis
- Immunocompromised stages
- Diabetes mellitus
- Osteomyelitis
- Cyclic or chronic neutropenia
- Langerhan's cell disease
- Dentin dysplasia type I
- Regional odontodysplasia
- Papillion-Lefevre syndrome
- Down syndrome
- Hypophosphatasia
- Scurvy

Swellings of the Palate

Traumatic

- Fracture of maxilla, alveolar process
- Hematoma
- Epulis
- Denture hyperplasia

Inflammatory

- Periapical, periodontal, gingival abscess of anterior maxillary teeth
- Osteomyelitis—acute and chronic
- Syphilis
- Tuberculosis
- Actinomycosis
- Quinsy (peritonsillar abscess)
- Infected cyst
- Mucormycosis
- Aspergillosis

- Cryptococcosis
- Toxoplasmosis

Necrosis

- Chemicals like phosphorus, arsenic
- Osteoradionecrosis
- Noma

Odontogenic cysts

- Radicular
- Residual
- Dentigerous
- Primordial
- Lateral periodontal cyst
- Gingival

Non-odontogenic cysts

- Nasopalatine or incisive canal cyst
- Globulomaxillary
- Traumatic
- Median alveolar and median palatine cyst
- Aneurysmal bone cyst
- Mucocele
- Botryoid cyst

Neoplasm

- Benign
- Malignant

Endocrine and metabolic disorders

- Fibrous dysplasia
- Paget's disease
- Hyperthyroidism
- Histiocytosis
- Caffey's disease
- Pregnancy tumor
- Leontiasis ossea

Salivary gland disorders

- Mucocele
- Tumor
- Necrotizing sialometaplasia

Developmental

- *Torus palatinus*
- Hyperplasia of palatal gland

Miscellaneous

- Impacted and supernumerary teeth
- Angioneurotic edema
- Teratoma
- Wegener's granulomatosis
- Gingival hyperplasia
- Midline lethal granuloma
- Tuberous sclerosis
- Papillomatosis in acanthosis nigricans

Swellings in the Submandibular (angle of mandible) Region**Traumatic**

- Hematoma—post-traumatic, postoperative and postextraction
- Fracture of mandible in symphysis area and body of mandible
- Denture hyperplasia
- Epulis fissuratum
- Pyogenic granuloma
- Traumatic granuloma
- *Myositis ossificans*

Cysts**Tumors****Metastasis****Inflammatory**

- Periapical, pericoronal
- Osteomyelitis
- Periostitis
- Cellulitis
- Ludwig's angina
- Tuberculosis
- Actinomycosis

Salivary Gland Dysfunction**Endocrine**

- Fibrous dysplasia
- Cherubism
- Caffey's disease

Lymphadenitis**Swelling of the Lip****Traumatic**

- From fall, assault, accidental, injury
- Lip sucking or lip biting or pipe smoking
- Trauma during epileptic and hysteric seizures
- Actinic cheilosis

Inflammatory

- Secondary to dental infection
- Carbuncle or abscess from mucus glands or hair follicle or acne
- Infected traumatic lesion
- Tuberculosis
- Leprosy
- Syphilis—chancre-gumma
- Actinomycosis
- Molluscum contagiosum
- Secondary to irradiation
- Condyloma acuminatum

Cyst

- Mucus extravasation or mucocele
- Lympho-epithelial cyst
- Epidermoid cyst
- Nasolabial cyst

Neoplasm**Allergy**

- Urticaria
- Angioneurotic edema
- Allergic macrocheilia

Developmental

- Congenital—double lip

Miscellaneous

- Amyloidosis
- Keratoacanthoma
- Papillomatosis
- Tuberous sclerosis
- Melkersson-Rosenthal syndrome
- Papillon Lefevre syndrome
- Cheilitis glandularis

Swellings in the Floor of the Mouth**Traumatic**

- Hematoma
- Fracture of alveolar process in symphysis region
- Denture granuloma
- Foreign body granuloma
- Epulis on lingual aspect of mandibular anterior teeth
- Epulis fissuratum, denture irritation hyperplasia

Inflammatory

- Abscess—periapical, gingival, periodontal, in anterior mandibular teeth
- Cellulitis—Ludwig's angina
- Infection following trauma
- Infection of Wharton's duct

Necrosis

- Chemical
- Post-irradiation

Cysts**Odontogenic**

- Radicular
- Dentigerous
- Gingival
- Residual
- Keratocyst
- Primordial

Non-odontogenic

- Traumatic
- Ranula
- Mucocele
- Sublingual dermoid cyst
- Lympho-epithelial cyst
- Cystic hygroma

Syndrome

- Sturge-Weber syndrome

Neoplasms**Benign epithelial tumors**

- Papilloma
- Adenoma
- Oncocytoma
- Oxyphilic adenoma

Malignant epithelial tumors

- Squamous cell carcinoma
- Malignant melanoma
- Mucoepidermoid carcinoma
- Adenocarcinoma
- Transitional cell carcinoma

Benign connective tissue tumors

- Hemangioma
- Lymphangioma
- Neurofibroma
- Leiomyoma
- Rhabdomyoma
- Fibroma
- Lipoma
- Granular cell myoblastoma

Malignant mesenchymal and other tumors

- Fibrosarcoma
- Hemangioendothelioma
- Reticular cell sarcoma
- Rhabdomyosarcoma
- Malignant lymphoma

Salivary gland swelling

- Sialadenitis
- Sialolithiasis
- Sjögren's syndrome
- Mikulicz's disease
- Salivary gland tumors
- Cysts of salivary gland

Allergy

- Angioneurotic edema

Swelling of Neck**Lateral neck swelling**

- Lymphadenitis
- Metastatic carcinoma to lymph nodes
- Lymphoma
- Parotid lesion
- Metabolic diseases
- Carotid body tumor
- Epidermoid cyst
- Cystic hygroma

Midline neck swelling

- Thyroglossal duct cyst
- Thyroid tumor
- Dermoid cyst

Extraoral Discharging Sinus**Developmental**

- Salivary fistula
- First or second branchial arch sinus or fistula
- Congenital lip pit

Inflammatory

- Periapical, periodontal and dentoalveolar abscess pointing extraorally
- Chronic osteomyelitis
- Syphilis
- Tuberculosis of jaw bone
- Actinomycosis
- Osteoradionecrosis
- Salivary fistula from suppurative sialadenitis
- Infected lymph node
- Infected cyst
- Infection secondary to trauma, injury
- Infection of various facial space
- Oronasal fistula

Neoplastic

- Intraoral malignancy with secondary growth
- Salivary gland malignancy

Perforations of the Palate**Congenital**

- Cleft palate

Inflammatory

- Osteomyelitis
- Syphilitic gumma
- Tuberculosis
- Infection of traumatic and chronic wound
- Mucormycosis
- Toxoplasmosis
- Blastomycosis
- Leprosy
- Wegener's granulomatosis

Traumatic

- Fracture of maxilla
- Use of suction disc for dentures
- Pizza burn, thermal burn

Neoplasm

- Squamous cell carcinoma
- Mucoepidermoid carcinoma
- Adenocystic carcinoma
- Osteosarcoma
- Lymphoma
- Midline lethal granuloma

Glossodynia**Local causes**

- Traumatic injury

- Median rhomboid glossitis
- Geographic tongue
- Lichen planus
- Oral submucous fibrosis
- Candidiasis
- Denture irritation
- Allergic reaction to denture material
- Malignant lesions
- Ulcerative and erosive lesions on tongue due to infection, trauma, allergy and systemic disease
- Xerostomia
- Trauma to lingual nerve
- Fusospirochetal infection
- TMJ dysfunction
- Chronic mouth breathing

Systemic diseases

- Diabetes
- Neuralgia—lingual, glossopharyngeal and facial
- Neuritis
- Nutritional deficiency
- Allergy
- Anemia
- Sjögren's syndrome
- Chronic gastritis
- Hypothyroidism
- Mercurialism
- AIDS

Psychological

- Emotional stress and strain
- Depression
- Neurosis
- Schizophrenia
- Mood disorders

Halitosis

Physiological

- *During infancy*—sweet odor
- *During development of dentition*—pungent odor
- Menstruation
- *Food habits*—alcohol, garlic, lemon, other aromatic beverages or food substances
- *Old age*—due to metabolic changes in periodontal tissue
- Hunger breath

Pathological

Local oral conditions

- Retention of food around the teeth (interdental area, flaps)
- Gingival and periodontal disease
- Deep carious lesion and necrotic pulp
- Coating of tongue
- Mouth breathing
- Denture and orthodontic appliance
- Oral soft tissue lesion
- Stomatitis
- Glossitis

- Pharyngitis
- *Habits*—smoking, tobacco and catechu

Systemic conditions

- *Odor from nasopharynx*—due to adenoma, rhinitis, sinusitis, postnasal drip, tonsillitis, tonsillar abscess, pharyngitis
- *From lung and bronchi*—bronchitis, lung abscess, pulmonary tuberculosis, lung malignancy
- *Diseases of gastrointestinal tract*—hyperacidity, gastritis, peptic ulcer, malignancy
- *Metabolic disorders*—diabetes, uremia and liver disease
- *Blood disorders*—anemia, agranulocytosis, leukemia, thrombocytopenia
- Salivary gland dysfunctions causing xerostomia
- *Dehydration states*—diarrhea, vomiting, diabetes insipidus,
- *Drug*—isosorbide dinitrate, iodine derivatives, diuretics, phenothiazines, immunosuppressive drugs and dimethyl sulfoxide

Enlargement of Cervical Lymph Nodes

Inflammation and Infection

Bacterial infections

- Specific bacterial infection
 - Syphilis
 - Tuberculosis
- Non-specific
 - Periodontal disease
 - Pericoronitis
 - Periapical infections

Viral infections

- Infection caused by herpes simplex
- Human immunodeficiency virus
- Cat scratch disease
- Infectious mononucleosis

Fungal infection

- Histoplasmosis
- Oral candidiasis

Parasitic infection

- Rickettsial infections

Allergic conditions

- Serum sickness

Primary neoplasm

- Lymphoma

Metastasis tumors

- Oral squamous cell carcinoma
- Metastasis carcinoma from the breast

Miscellaneous conditions

- Non-tender lymphoid hyperplasia
- Collagen disease
- Sarcoidosis
- Leukemia

Trismus**Traumatic****Intra-articular**

- Trauma to growth center or developing condyle
- Monoarticular arthritis like spasm or subluxation (due to chronic malocclusion)
- Trauma to articular disc
- Trauma to capsular or temporomandibular ligament
- Fracture with or without dislocation and displacement of condylar head
- Ankylosis
- Foreign body in the joint area

Extra-articular

- Trauma to muscle
- Trauma during extraction
- Faulty mandibular block
- Fracture of coronoid process
- Fracture of zygomatic arch
- Fracture of styloid process
- Misplaced fixative or augmentative device

Inflammatory**Intra-articular**

- Pyogenic infection
- Rheumatic fever
- Rheumatoid arthritis
- Gout
- Tuberculosis
- Syphilis
- Actinomycosis
- Osteomyelitis
- Synovitis

Extra-articular

- Pericoronitis
- Acute and chronic osteomyelitis
- Acute and chronic dentoalveolar abscess

- Cancrum oris or noma
- Abscess in various fascial spaces like infratemporal, lateral pharyngeal, submasseteric, and pterygomandibular spaces
- Phosphorus necrosis
- Quinsy (peritonsillar abscess)
- Infection of ear or otitis media
- Mumps
- Acute generalized stomatitis
- Angular cheilitis
- Pharyngitis

Congenital and developmental disorders

- Unilateral or bilateral condylar hyperplasia
- Unilateral or bilateral exostosis of coronoid
- Hyperplasia of coronoid process and zygomatic arch
- Fusion of coronoid process with zygomatic arch
- Absence of coronoid process

Neoplastic**Intra-articular****Benign**

- Osteoma
- Chondroma
- Osteochondroma
- Myxoma
- Benign giant cell tumor
- Trotter's syndrome

Malignant

- Osteosarcoma
- Chondrosarcoma
- Fibrosarcoma
- Metastatic carcinoma

Extra-articular

- Benign and malignant tumors of mandible and maxilla mainly in premolar and molar area

Summary table of the effects of different inflammatory processes on the periapical tissues and the resultant radiographic appearances

Stage of inflammation	Underlying inflammatory changes	Radiographic appearance
Initial acute inflammation	Inflammatory exudate accumulates in the apical periodontal ligament space—acute apical periodontitis	Widening of the radiolucent line of periodontal ligament space or no apparent changes evident
Initial spread of inflammation	Resorption and destruction of the apical bony socket—periapical abscess	Loss of radiopaque line of lamina dura at the apex
Further spread of inflammation	Further resorption and destruction of the apical alveolar bone	Area of bone loss at the tooth apex
Initial low-grade chronic inflammation	Minimal destruction of the apical bone. The body's defense systems lay down dense bone in the apical region	No apparent bone destruction but dense sclerotic bone evident around the tooth apex (sclerosing osteitis)
Latter stages of chronic inflammation	Apical bone is resorbed and destroyed and dense bone is laid down around the area of resorption—periapical granuloma or radicular cyst	Circumscribed well defined radiolucent area of bone loss at the apex, surrounded by dense sclerotic bone

- Malignant tumors of nasopharynx
- Malignant tumors of maxillary sinus
- Parotid tumors

Cystic

Extra-articular

- All large cystic lesion affecting mandible, ramus and posterior part of maxilla

Systemic

- Tetanus
- Tetany
- Fibrous dysplasia
- Paget's disease
- Acromegaly

Miscellaneous

- Epilepsy and hysteria
- Hydrophobia
- Sudden physical, chemical and electrical shock
- Hemorrhage in medulla oblongata
- Brain tumor
- Scleroderma
- Strychnine poisoning
- Myelofibrosis
- Amylotrophic lateral sclerosis
- Oral submucous fibrosis
- Osteoradionecrosis
- Myositis ossificans
- Disuse atrophy
- Myofascial pain dysfunction syndrome (MPDS)
- Extensive burns of face with keloid and scar formation
- Dystrophic epidermolysis bullosa

Hemorrhage

Local causes

- Post-extraction, post-surgical and post-traumatic
- Infections—viral, bacterial, fungal, parasitic and spirochete
- Oral ulcerative lesions—stomatitis, glossitis
- Oral exophytic soft tissue lesions—pyogenic granuloma, pregnancy tumor
- Local irritants leading to gingivitis and periodontitis
- Rupture of blood containing bulla
- Congenital hamartomas—hemangioma, hereditary hemorrhagic telangiectasia, arteriovenous malformation

Hemorrhage due to platelet disorders

- Thrombocytopenia
- Thrombocytosis
- Thrombasthenia
- Glanzmann's disease
- Aldrich syndrome

Hemorrhage due to coagulation diseases

- Hemophilia
- Christmas disease

- von Willebrand's disease
- Deficiency of Stuart factor
- Multiple myeloma
- Systemic lupus erythematosus
- Diffuse intravascular coagulation
- Macroglobulinemia

Hemorrhage due to systemic diseases

- Scurvy
- Diabetes mellitus
- Septic embolism in bacterial endocarditis
- Meningococemia
- Systemic viral infection
- Allergy
- Anti-coagulant therapy
- Graft versus host reaction
- Sturge-Weber syndrome

Angular cheilitis

- Infections
 - Candidiasis
 - Herpes labialis
- Unhygienic appliances
- Malabsorption syndrome
- Diabetes
- Change in vertical dimension
- Xerostomia
- Nutritional deficiency
 - Anemia
 - Vitamin deficiency
 - Protein deficiency
 - Plummer-Vinson syndrome
- Split papule of syphilis
- Allergic reaction to lipstick
- Cold sore

Sialorrhea

- Acute inflammation of oral mucosa
- Fracture of jaw bone
- During eruption of teeth in infants
- Mental retardation
- Neurosis
- Psychosis
- Parkinsonism
- Schizophrenia
- Epilepsy
- Acrodynia (mercury poisoning)
- Rabies
- Familial dystonia
- Drugs like sialogogue

Xerostomia

Factor affecting salivary center

- Emotional disturbance like stress, strain
- Depression

- Hysteria
- Neurosis

Factor affecting autonomous nervous system

- Encephalitis
- Brain tumor
- Neurological operation

Factor affecting salivary gland

- Developmental
- Inflammatory
- Tumor of salivary gland
- Sialolithiasis
- Sjögren's syndrome
- Mikulicz's disease
- Atrophy of gland

Alteration in fluid and electrolyte balance

- Dehydration
- Diarrhea
- Vomiting
- Diuresis
- Diabetes insipidus
- Congestive cardiac failure
- Ascites
- Liver cirrhosis

Drugs

- Anticholinergic
- Antidepressants
- Sympathomimetics
- Opium derivatives
- Antipsychotic
- Antihistamine
- Diuretics
- Sedatives
- Digitalis
- Steroids
- Chemotherapeutic agents

Miscellaneous

- Malnutrition
- Nutritional and vitamin deficiency
- Radiation
- Toxemia
- Habits (smoking, betel nut chewing)
- Chronic alcoholism

Saliva Drooling at Corner of Mouth

- Oral infection, throat infection
- Jaw fracture
- Psychosis
- Schizophrenia
- Rabies
- Acrodynia
- During eruption of teeth in infant

Discoloration of the Teeth

Extrinsic

- Habits—tobacco, catechu
- Chromogenic bacteria
- Poor oral hygiene
- Oral drugs
- Iatrogenic
- Tattoo made by patient
- Chlorhexidine mouthwash
- Medicaments like AgNO₃, iodine, iron

Intrinsic

- Erythroblastosis fetalis due to Rh incompatibility
- Neonatal jaundice
- Congenital porphyria
- Tetracycline therapy during formation of teeth
- Cystic fibrosis
- Osteogenesis imperfecta
- Dentinogenesis imperfecta
- Amelogenesis imperfecta
- Fluorosis
- Enamel opacities
- Non-vital teeth or internal resorption
- Congenital heart disease
- Acute exanthematous disease
- Turner's teeth

Macroglossia

Congenital or developmental

- Mongolism
- Lingual thyroid or polyp

Inflammatory

- Syphilis
- Amoebic dysentery
- Ludwig's angina
- Pneumonia
- Typhoid
- Tuberculosis
- Blastomycosis
- Infected wound
- Actinomycosis

Neoplasms

- Hemangioma (diffuse type)
- Neurofibromatosis
- Lymphangioma (diffuse type)

Systemic

- Pellagra
- Down's syndrome
- Myxedema
- Acromegaly
- Amyloidosis
- Uremia
- Gardner's syndrome
- Diabetes

- Scurvy
- Dyskinesia chorea
- Melkersson-Rosenthal syndrome
- Sturge-Weber syndrome
- Hurler's syndrome
- Beckwith's hypoglycemia syndrome
- Tuberous sclerosis

Orofacial pain

Extra-cranial causes

Dental and oral

- Dentinal hypersensitivity
- Pain from disorders of pulp
 - Hyperemia
 - Acute pulpitis
 - Chronic pulpitis
- Pain from disorders of periodontium
- Mucogingival pain
 - Stomatitis
 - Gingivitis
 - Glossitis
 - Glossodynia
- Osseous and periosteal pain
 - Dry socket
 - Periostitis
 - Osteomyelitis
- From disorders of ear and eye
- Enlargement of salivary glands

Pain from paranasal sinuses

- Sinusitis
- Tumors of the sinus

Musculoskeletal

- Myofacial pain
- Temporomandibular joint arthropathy
- Cervical spine disorders
- Trotter's syndrome
- Eagle's syndrome

Intra-cranial causes

- Traction disorders of pain sensory structure of the brain
- Neoplasms, aneurysms, hematoma, hemorrhage or edema
- Displacement of great venous sinus
- Distortion and dilation of intracranial vessels

Vascular pain

- Migraine headache
- Cluster headache
- Tension headache
- Temporal headache
- Carotodynia
- Angina pectoris or myocardial infarction

Neurogenic pain

Paroxysmal

- Trigeminal neuralgia
- Glossopharyngeal neuralgia
- Geniculate neuralgia

Differentiation pain syndrome

- Atypical odontalgia
- Traumatic neuroma
- Neuritis
- Reiter's sympathetic dystrophy

Psychogenic pain

- Anxiety and depression
- Delusional or hallucination pain
- Hysterical or hypochondriac pain

Classification by Bells

Somatic

- Superficial—mucogingival
- Deep visceral—musculoskeletal

Neurogenic

- Neuropathy—neuralgia and neuritis
- Deafferentation syndrome

Psychogenic

- Conversion hysteria
- Delusional pain

Sloughing Pseudomembranous Necrotic White Lesion

- Plaque
- Traumatic ulcer
- Diffuse gangrenous stomatitis
- Diphtheria
- Noma
- Candida endocrinopathy syndrome
- Chemical burns
- ANUG
- Candidiasis
- Eosinophilic granuloma
- Superficial abscess
- Syphilitic chancre and mucous patches

Osteoporosis

- Osteogenesis imperfecta
- Post-menopausal osteoporosis
- Hyperthyroidism
- Diabetes
- Old age
- Gonadal osteoporosis
- Idiopathic osteoporosis
- Renal acidosis
- Oxalosis
- Acromegaly
- Adaptation syndrome
- Hypervitaminosis D
- Hypovitaminosis C

Depapillation of Tongue

Congenital cause

- Familial dystonia
- Epidermolysis bullosa
- Dyskeratosis congenita
- Endocrine candidiasis

Developmental

- Geographic tongue
- Median rhomboidal glossitis
- Central papillary atrophy

Chronic trauma**Nutritional and hematological abnormalities**

- Pellagra
- Riboflavin
- Conditional deficiency
- Plummer-Vinson syndrome

Medication

- Antibiotic
- Anticholinergic agent
- Cancer chemotherapeutic agent

Peripheral vascular disease**Chronic candidiasis****Tumor**

- Squamous cell carcinoma
- Epidermoid carcinoma

Miscellaneous

- Diabetes mellitus
- Oral submucous fibrosis

Atrophic Lesion of Oral Mucosa of Tongue**Developmental**

- Benign migratory glossitis
- Median rhomboidal glossitis

Systemic condition

- Endocrine—diabetes mellitus
- Vitamins like B₂, B₅, B₆, B₉ and B₁₂ deficiency
- Blood disorders—pernicious anemia and iron deficiency anemia

Infection

- Syphilis
- Chronic candidiasis

Oral submucous fibrosis**Mucocutaneous**

- Atrophic lichen planus
- Discoid lupus erythematosus
- Dyskeratosis congenita
- Scleroderma
- Xerostomia

Retarded Eruption of Teeth**Local causes**

- Loss of space

- Abnormal crypt position
- Overcrowding
- Additional teeth
- Retention of deciduous predecessor
- Dentigerous and eruption cyst
- Hereditary gingival fibromatosis

Systemic causes

- Congenital hypopituitarism
- Congenital hypothyroidism
- Down syndrome
- Cleidocranial dysplasia
- After radiation
- Rickets

Loosening or Early Loss of Teeth**Local causes**

- Inflammatory periodontal disease
- Trauma
- Juvenile periodontitis

Systemic causes

- Down syndrome
- Diabetes mellitus
- Neutropenia
- Hypophosphatasia
- Papillon lefevre syndrome
- Ehlers-Danlos syndrome
- AIDS related disorders

Others

- Acrodynia
- Neoplasm
- Eosinophilic granuloma

Malformed Teeth

- Local infection or trauma
- Radiotherapy
- Congenital syphilis
- Down syndrome
- Ectodermal dysplasia
- Rickets

Hairy Tongue

- Dehydration
- Debilitated patient
- Long illness
- Painful oral condition restricted tongue movement
- Use of local and systemic medication like systemic antibiotic, topical H₂O₂ and perborate

Causes that Cause Red Lesions**Marked increased in hemoglobin concentration of articulating blood**

- Polycythemia

Vascular dilation from**Inflammation (erythema)**

- Mechanical trauma (cheek biting, ill fitting denture)
- Thermal trauma (hot food)
- Chemical trauma
- Infection (cellulitis and Ludwig angina)
- Allergy or autoimmune disease
- Ulcer with inflamed rim (recurrent herpetic ulcer)

Congenital defect

- Hemangioma

Extravasation of blood (trauma or homeostatic disease)**Atrophy or thinning of mucosa****Leukopenia****Infections****Bacterial**

- Typhoid
- Paratyphoid fever
- Brucellosis
- Tularemia (early)

Viral and rickettsial

- Influenza
- Measles
- Rubella
- Chickenpox
- Infectious hepatitis
- Colorado tick fever
- Dengue
- Yellow fever

Protozoal

- Malaria
- Relapsing fever
- Kala azar

Any overwhelming infection

- Miliary tuberculosis
- Septicemia

Hemopoietic disorders

- Gaucher's disease
- Pernicious anemia
- Aplastic anemia
- Chronic hypochromic anemia
- Aleukemic leukemia
- Agranulocytosis

Chemical agents**Agents commonly producing leukopenia in all patient if given in sufficient dose**

- Mustards (sulfur and nitrogen mustards)
- Urethane
- Busulfan
- Benzene
- Antimetabolites

Agents occasionally associated with leukopenia apparently as a result of individual sensitivity

- Analgesics, sedative and anti-inflammatory
- Antithyroid drug
- Anticonvulsant
- Sulfonamides
- Antihistamine
- Antimicrobial agents
- Tranquilizers

Physical agents

- X-ray radiation and radioactive substance

Anaphylactic shock and early stages reaction of foreign protein**Disease of unknown etiology**

- Liver cirrhosis
- Disseminated erythematosis
- Cyclic neutropenia

Basophilia**Blood disorders**

- Chronic myelocytic leukemia
- Chronic anemia
- Hodgkin's disease

Splenectomy**Infection**

- Chronic inflammation of accessory tissue
- Smallpox
- Chickenpox

Myxedema**After injection of foreign proteins****Some cases of nephrosis****Neutrophilia****Acute infection**

- Coccal
- Bacilli
- Fungi
- Spirochetes
- Virus
- Rheumatic fever
- Diphtheria
- Smallpox

Inflammatory

- Coronary thrombosis
- Gout
- Collagen vascular disease
- Burns
- Hypersensitivity reaction

Intoxication

- Uremia

- Diabetes acidosis
- Poisoning by chemical and drugs like lead, mercury, digitalis, insect venoms, black widow spider

Acute hemorrhage*Acute hemolysis***Malignant tumor of**

- Gastrointestinal tract
- Liver
- Bone marrow

Blood disorders

- Myelocytic leukemia
- Polycythemia
- Myelofibrosis
- Myeloid metaplasia
- Chronic idiopathic neutropenia
- Hereditary neutrophilia

Miscellaneous

- Physiologic in the newborn
- During labor
- After repeated vomiting
- Convulsion
- Paroxysmal tachycardia
- After epinephrine injection

Eosinophilia*Allergic*

- Bronchial asthma
- Urticaria
- Angioneurotic edema
- Hay fever
- Allergic rhinitis
- Drug sensitivity

Skin disease

- Pemphigus
- Dermatitis herpetiformis
- Bullous pemphigoid

Parasitic infection

- Trichinosis
- Echinococcosis disease

Blood disorders

- Chronic myelocytic leukemia
- Polycythemia vera
- Hodgkin's disease
- Pernicious anemia

Infection

- Scarlet fever
- Chorea
- Erythema multiforme

Malignant disease of any type

Following irradiation

Miscellaneous

- Pulmonary infiltration with eosinophilia
- Tropical eosinophilia
- Polyarteritis nodosa
- Rheumatoid arthritis
- Sarcoidosis
- Certain poison

Inherited**Idiopathic****Lymphocytosis****Acute infection**

- Infectious mononucleosis
- Acute infectious lymphocytosis
- Infectious hepatitis

Chronic infection

- Tuberculosis
- Secondary and congenital syphilis
- Undulant fever

Lymphocytic leukemia**Lymphosarcoma****Heavy chain disease****Hemopoietic disorders**

- Neutropenia
- Exanthema

Monocytosis**Bacterial infection**

- Tuberculosis
- Subacute bacterial endocarditis
- Syphilis
- Brucellosis
- Typhoid

Protozoan and rickettsial infection

- Malaria
- Rocky Mountain spotted fever
- Typhus
- Kala azar
- Trypanosomiasis
- Oriental sore

Blood disorders

- Lymphoma
- Leukemia
- Hodgkin's disease
- Multiple myeloma

Lipid storage disease

- Gaucher disease

Malignant neoplasm

- Carcinoma of ovary, breast and stomach

Collagen vascular disease

- Lupus erythematosus
- Rheumatoid arthritis

Granulomatous disease

- Sarcoidosis
- Ulcerative colitis
- Regional arteritis

Chronic high dose steroid therapy**Peripheral Plasmocytosis****Infection****Viral**

- Rubella
- Rubeola
- Varicella
- Infectious mononucleosis

Bacterial

- Streptococcal
- Diplococcal
- Syphilis
- Tuberculosis

Protozoal

- Malaria
- Trichinosis

Serum Sickness**Drugs**

- Penicillin
- Sulfisoxazole

Antitoxins

- Equine tetanus
- Equine diphtheria

Neoplasm**Hematological**

- Plasma cell leukemia
- Chronic lymphocytic leukemia

Nonhematological

- Breast
- Prostate

Miscellaneous

- Transfusion
- Hyperimmunization
- Trauma

Periapical Radiolucency

- Acute apical periodontitis
- Periapical abscess
- Periapical granuloma
- Periapical cyst
- Dentigerous cyst

- Periapical scar
- Giant cell granuloma
- Benign and malignant tumor including secondary metastatic deposits
- Lymphoreticular tumors of bone
- Langerhan's cell disease
- Periapical cemental dysplasia
- Surgical defect
- Osteomyelitis

Monolocular and Multilocular Radiolucency**Monolocular lesion**

- Radicular cyst
- Residual cyst
- Dentigerous cyst
- Lateral periodontal cyst
- Nasopalatine duct cyst
- Simple bone cyst
- Calcifying epithelial odontogenic tumor
- Adenomatoid odontogenic tumor
- Primary bone tumors
- Secondary metastasis tumor
- Multiple myeloma
- Eosinophilic granuloma
- Fibro-cemento-osseous lesion
- Stafne's bone cavity

Multilocular lesion

- Odontogenic keratocyst
- Ameloblastoma
- Ameloblastic fibroma
- Ameloblastic fibro-odontoma
- Odontogenic myxoma
- Central giant cell granuloma
- Brown tumor
- Cherubism
- Aneurysmal bone cyst
- Metastatic tumor of the jaw
- CEOT
- Fibrous dysplasia
- Burkitt's lymphoma
- Squamous odontogenic tumor

Pericoronal Radiolucency

- Dentigerous cyst
- Ameloblastoma
- Calcifying odontogenic cyst
- Adenomatoid odontogenic tumor
- Pericoronal space
- Unicystic ameloblastoma
- Ameloblastic fibroma
- Envelopmental primordial cyst

Inter-radicular Radiolucency

- Primary tooth crypt
- Mental foramina
- Nutrient canal
- Bony periodontal pocket

- Malignancy
- Lateral periodontal cyst
- Median mandibular cyst
- Paradental cyst
- Furcation involvement
- Lateral radicular cyst
- Traumatic bone cyst
- Odontogenic tumor
- Globulomaxillary tumor
- Incisive canal cyst
- Histiocytosis-X
- Osteoradionecrosis

Solitary Cyst-like Radiolucency not Necessary Contacting Teeth

- Primordial cyst
- Traumatic cyst
- Residual cyst
- Odontogenic keratocyst
- Aneurysmal bone cyst
- Cementoma
- Central fibroma
- Ameloblastoma
- Giant cell granuloma
- Midpalatal cyst
- Cementifying ossifying fibroma
- Benign non-odontogenic tumor
- Central squamous cell carcinoma
- Myxoma

Multiple Separate Well-defined Radiolucency

- Multiple myeloma
- Basal cell nevus syndrome
- Multiple cyst or granuloma
- Histiocytosis-X
- Cherubism
- Nodular central masses
- Neurofibromatosis
- Hurler's and Hunter's syndrome

Generalized Rarefaction of Jaw Bones

- Hyperparathyroidism
- Osteoporosis
- Osteogenic imperfecta
- Hypervitaminosis D
- Diabetes
- Osteomalacia
- Leukemia
- Paget's disease
- Multiple myeloma
- Lymphosarcoma

Mixed Radiolucent—Radiopaque Lesion Associated with Teeth

- Calcifying crown of developing teeth
- Tooth root with rarefying osteitis
- Rarefying and condensing osteitis
- Cementifying and ossifying fibroma
- Periapical cementoma—intermediated stage
- Foreign bodies

- Odontoma
- Osteomyelitis chronic

Pericoronal Mixed Lesion

- Odontoma—intermediate stage
- AOT
- Keratinizing and calcifying odontogenic cyst
- CEOT
- Odontogenic fibroma
- Eruption sequestrum
- Cystic odontoma
- Ameloblastic fibroma

Mixed Radiolucent-radiopaque Lesion not Necessary Contacting Teeth

- Chronic osteomyelitis
- Osteoradionecrosis
- Fibrous dysplasia
- Paget's disease—intermediate stage
- Central hemangioma
- Osteoid osteoma
- Cementifying and ossifying fibroma
- Osteogenic sarcoma
- Chondroma and chondrosarcoma
- Ossifying subperiosteal hematoma
- Calcifying epithelial odontogenic tumor

Variable Radiopacities

Abnormalities of the teeth

- Unerupted and misplaced teeth including supernumeraries
- *Odontoma*—compound and complex
- Root remnants
- Hypercementosis

Condition affecting the bone

Developmental

- *Exostosis including tori*—mandibular or palatal

Inflammatory

- *Low grade chronic infection*—sclerosing osteitis
- *Osteomyelitis*—sequestra involucrum formation

Tumors odontogenic (late stages)

- Calcifying epithelial odontogenic tumor
- Adenomatoid odontogenic tumor
- Calcifying odontogenic cyst

Non-odontogenic tumor

- *Benign*—osteoma, chondroma
- *Malignant*—osteosarcoma, osteogenic secondary metastases

Fibro-cemento-osseous

- Fibrous dysplasia
- Periapical cemental dysplasia
- Gigantiform cementoma
- Benign cementoblastoma
- Cemento-ossifying fibroma

Other

- Paget's disease
- Osteopetrosis

Superimposed soft tissue calcifications

- Salivary calculi
- Calcified lymph node
- Calcified vessels
- Phleboliths
- Calcified ACE scars

Foreign bodies

- Intrabony
- Within the soft tissue
- On or overlying the skin

Periapical radiopacities**True**

- Condensing osteitis
- Periapical idiopathic osteosclerosis
- Mature periapical cementoma
- Foreign bodies
- Hypercementosis

Projected

- Sialoliths
- Phleboliths
- Arterial calcification
- Retained root tips
- Exostosis tori and periapical osteoma
- Calcified lymph nodes

Multiple Separate Radiopacities

- Multiple chondroma
- Sickle cell sclerosis
- All solitary radiopacities not necessary contacting teeth

Solitary Radiopacities not Necessary Containing Teeth**True**

- Tori, exostosis and periapical osteoma
- Unerupted, impacted and supernumerary teeth
- Retained root
- Idiopathic osteosclerosis
- Cementifying and ossifying fibroma
- Chondroma
- Chondrosarcoma
- Mature osteoblastoma
- Osteogenic sarcoma
- Fibrous dysplasia
- Mature cementoma
- Sclerosing osteomyelitis and diffuse sclerosing osteomyelitis
- Proliferative periostitis

Projected

- Anatomic radiopacities
- Foreign bodies
- Pathologic soft tissue
- Arterial calcification
- Rhinoliths and antroliths

Generalized Radiopacities

- Gardener's syndrome
- Fluorosis
- Caffey's disease
- Adenomatoid odontogenic tumor
- Metastatic carcinoma of prostate
- von Buchan disease
- Osteopetrosis

Thickened Periodontal Ligament Space

- Periapical abscess
- Current orthodontic therapy
- Increase occlusal friction
- Systemic sclerosis
- Sarcoma infiltration
- Carcinoma infiltration

Loss of Lamina Dura

- Periapical infections
- Fibrous dysplasia
- Paget's disease
- Osteoporosis
- Normal anatomical variation
- Hyperparathyroidism
- Leukemia
- Cushing syndrome
- Hypophosphatasia
- Osteomalacia
- Multiple myeloma

Different Type of Periosteal Reaction and their Cause**Regular type****Parallel type**

- Onion peel appearance
- Eosinophilic granuloma
- Chronic osteomyelitis
- Codman's triangle
- Osteosarcoma

Radiating type

- Sunray appearance
- Osteosarcoma
- Hair on end appearance
- Paget's disease
- Central hemangioma

Irregular type

- Osteomyelitis
- Fracture
- Osteogenic malignancy
- Subperiosteal bleeding
- Leukemia
- Histiocytosis
- Arthritis
- Rheumatism

Typical Features of the Lesion*Typical clinical feature*

<i>Name of disease</i>	<i>Typical feature</i>
Ameloblastoma	Egg shell cracking
Pyogenic granuloma	Hour-glass appearance
Hodgkin's disease	Bimodal age incidence peak
Psoriasis	Auspitz's sign
Lichen planus	Wickham's striae
Pemphigus	Nikolsky's sign
Scarlet fever	Strawberry and Raspberry tongue
Diphtheria	Diphtheritic membrane
Wegener's granulomatous	Strawberry gingivitis
Tetany	Risus sardonicus
Behcet's syndrome	Pathergy test positive
Measles	Koplik's spot
Mild restricted muscular dystrophy	Tapir-lips
Leukokeratosis nicotina glossi	Golf ball appearance
Bell's palsy	Masklike or expressionless appearance
Rickets	Rachitic rosary, pigeon breast
Pseudoxanthoma elasticum	Hound dog

Typical radiological feature

<i>Typical radiological feature</i>	<i>Name of disease</i>
Soap bubble appearance	Ameloblastoma, aneurysmal bone cyst, central hemangioma
Honeycomb pattern	Calcifying epithelial odontogenic cyst, odontogenic myxoma, hemangioma, central giant cell granuloma
Driven snow appearance	Calcifying epithelial odontogenic cyst
Sun burst appearance	Hemangioma, osteosarcoma
Sunray appearance	Osteosarcoma, hemangioma, osteoblastoma
Hair on end appearance	Sickle cell anemia, thalassemia
Tennis racket	Odontogenic myxoma
Moth eaten	Early stage of osteosarcoma, squamous cell carcinoma, osteomyelitis, osteoradionecrosis, leukemia, malignant lymphoma
Teeth standing in space or floating teeth	Histiocytosis-X, severe periodontitis, malignant lymphoma
Ground glass	Fibrous dysplasia, Paget's disease, hyperparathyroidism, ossifying fibroma
Orange peel	Fibrous dysplasia
Cotton wool	Paget's disease
Downward bowing	Cemento-ossifying fibroma
Mass of coral	Calcified lymph node
Antral halo	Acute sinusitis

<i>Typical radiological feature</i>	<i>Name of disease</i>
Hanging drop appearance in maxillary sinus	Blow out orbital fracture
Ely's cyst	Osteoarthritis
Pepper pot skull	Hyperparathyroidism
Step ladder pattern	Sickle cell anemia
Tree in winter appearance	Normal sialographic appearance of parotid gland
Bush in winter appearance	Normal sialographic appearance of submandibular gland
Sausage link appearance	Sialographic appearance of sialodochitis (ductal inflammation/infection)
Snowstorm appearance	Sialographic appearance of Sjögren's syndrome
Sialectasis	Sialographic appearance of sialadenitis
Ball in hand appearance	Sialographic appearance of intrinsic benign tumor
Codman's triangle	Osteogenic sarcoma
Balloon like appearance	Follicular cyst
Candlestick appearance	Pyknodysostosis and progressive systemic sclerosis
Chalk like appearance	Osteopetrosis, pyknodysostosis, hyperparathyroidism
Cherry blossom pattern	Sialographic appearance of Sjögren's syndrome
Eggshell appearance	Ameloblastoma, multilocular cyst
Filling defect	Salivary gland tumor
Mottled appearance	Fibrous dysplasia, ossifying fibroma
Onion peel (skin) appearance	Chronic osteomyelitis, eosinophilic granuloma, Ewing's sarcoma
Permeated type	Carcinoma of gingiva, squamous cell carcinoma of maxilla
Pear shaped appearance	Globulomaxillary cyst
Pencil line appearance	Ameloblastoma, traumatic bone cyst and CEOC
Pressure type appearance	Squamous cell carcinoma of the gingiva
Punched out appearance	Multiple myeloma
Sand like appearance	Adenoameloblastoma, CEOC and CEOT
Salt and paper appearance	Hyperparathyroidism, ABC and giant cell granuloma
Scalloping pattern (margins)	Dentigerous cyst, traumatic bone cyst, ABC and giant cell tumor
Spiked root	Malignant histiocytoma, Burkitt's lymphoma
Beaten silver	Craniofacial dysostosis (Crouzon' disease)
Sharpened pencil or mouth piece of flute	Rheumatoid arthritis of TMJ
Thumb print	Fibrous dysplasia

Typical histological features

<i>Typical histological features</i>	<i>Name of disease</i>
Starry sky	Burkitt's lymphoma, infective mononucleosis, polycythemia
Rushton bodies	Dentigerous cyst
Reed-Sternberg cell	Hodgkin's disease
Dropping off effect	Junctional nevus
Saw tooth appearance	Lichen planus
Antoni type A and type B tissue	Neurilemmoma
Honeycomb or Swiss cheese pattern	Adenoid cystic carcinoma of salivary gland
Picket fence or tombstone	Primordial cyst
Liesegang ring	Calcifying epithelial odontogenic tumor
Safetypin appearance	Granuloma inguinale
Lipschutz bodies	Herpes simplex infection
Anitschkow cell	Aphthous ulcer, sickle cell anemia, megaloblastic anemia and iron deficiency anemia
Henderson-Paterson inclusion	Molluscum contagiosum
Dilapidated brick wall effect	Familial benign chronic pemphigus
Cartwheel or checkerboard appearance	Multiple myeloma
Tobacco cells or cell in cells	Hereditary benign intra-epithelial dyskeratosis
Lava flowing around boulder'	Dentin dysplasia (shield type I)

Various drug effect on oral cavity

<i>Tissue</i>	<i>Drug effect</i>	<i>Drugs used</i>
Teeth	Discoloration Root anomalies	Tetracycline Chlorhexidine Phenytoin Cytotoxic
Gingiva	Swelling	Phenytoin Cyclosporine Nifedipine
Salivary gland	Dry mouth	Tricyclic antidepressant Phenothiazine Antihypertensive Lithium
Taste	Disturbed	Metronidazole Penicillamine
Facial movements	Dyskinesia	Phenothiazines Metoclopramide
Mucosa	Thrush Ulcers Lichenoid lesions Erythema multiforme	Broad spectrum antimicrobial Corticosteroids Cytotoxic drugs NSAID Barbiturates Sulphonamides

Summary of the main mandibular and maxillary fracture site and the common projection used for each side**Mandibular**

<i>Fracture site</i>	<i>Commonly used projection</i>
Angle	Dental panoramic tomography or oblique lateral Postero-anterior of jaws
Condylar neck	Dental panoramic tomography or oblique lateral Postero-anterior of jaws (for low neck fracture) Reverse Towne's (for high condylar neck)
Body	Dental panoramic tomography or oblique lateral Postero-anterior of jaws periapical of involved teeth, Lower 90° occlusal
Canine region	Dental panoramic tomography or oblique lateral Periapical of involved teeth, True lateral skull
Symphysis	Lower 45° occlusal, Lower 90° occlusal
Ramus	Dental panoramic tomography or oblique lateral Postero-anterior of jaws
Coronoid process	Dental panoramic tomography or oblique lateral 0° occipitomenal

Maxillary

<i>Fracture type/site</i>	<i>Commonly used radiograph</i>
Dento-alveolar	Periapical, Upper standard occlusal, Upper occlusal
Le Fort I	0° occipitomenal, 30° occipitomenal, True lateral skull (brow-up)
Le Fort II	0° occipitomenal, 30° occipitomenal, True lateral skull (brow-up)
Le Fort III	0° occipitomenal, 30° occipitomenal, True lateral skull (brow-up), Coronal section tomography, CT scan/3D reconstruction
Zygomatic complex	0° occipitomenal, 30° occipitomenal, Submentovertex
Nasoethmoidal	0° occipitomenal, 30° occipitomenal, True lateral skull (brow-up) Soft tissue lateral view of the nose, CT /3D reconstruction
Orbit	0° occipitomenal, True lateral skull (brow-up), Postero-anterior 25° CT/3-D reconstruction

Various lymph nodes in the head and neck region and their area of drainage

<i>Lymph nodes</i>	<i>Area of drainage</i>	<i>Discharge</i>
Occipital	Posterior scalp	Spinal accessory nodes
Retromandibular	Scalp, posterior ear, back of external auditory meatus	Internal jugular nodes
Superficial parotid	Lateral and frontal scalp, lateral ear, external auditory canal, eyelids	Superficial cervical nodes Internal jugular nodes
Deep parotid	Parotid gland, orbit, lateral eyelid, conjunctiva, superficial thyroid nodes	Internal jugular nodes
Buccal	Medial eyelids, skin and mucous membrane of the nose and cheeks	Mandibular nodes
Mandibular	Similar to buccal lymph nodes	Submandibular nodes
Submental	Tip of the tongue, anterior floor of mouth, anterior lower gingiva, middle lower lip, chin	Submandibular nodes
Submandibular	Salivary gland, upper and lower lips, cheeks, gingiva teeth, anterior palatine pillar, soft palate, anterior two-third of the tongue	Internal jugular nodes
Superficial cervical	Parotid nodes	Internal jugular nodes
Internal jugular	All the nodes mentioned above and pharynx, tonsil, tongue, palate, larynx	Subclavian vein, right side thoracic duct
Spinal accessory	Occipital nodes, retroauricular nodes, back of heads, nape and lateral aspect of the neck	Supraclavicular nodes
Supraclavicular	Spinal accessory nodes, posterior triangle submandibular nodes	Joins inferior internal jugular

Firm non-hemorrhagic soft tissue growth of oral cavity

- Fibromatosis
- Torus
- Irritation fibroma
- Peripheral fibroma
- Myxoma
- Neurofibroma
- Lipoma
- Granular cell myoblastoma
- Sialadenitis
- Tumor of salivary gland

Hemorrhagic or easily bleeding soft tissue growth of oral cavity

- Parulis
- Eosinophilic granuloma
- Epulis fissuratum
- Peripheral giant cell granuloma
- Pyogenic granuloma
- Pregnancy tumor
- Squamous cell carcinoma
- Lymphomas
- Leukemia
- AIDS

Compressible soft tissue growth of oral cavity

- Eruption cyst
- Mucocele
- Mucous cyst
- Ranula
- Gingival cyst
- Nasoalveolar cyst
- Epidermoid cyst
- Cavernous
- Capillary hemangioma
- Lymphangioma
- Cystic hygroma

Various odors related to systemic disease

- Sour—digestive dysfunction
- Fetid—ANUG
- Urinous—uremia, kidney dysfunction
- Acetone—diabetes mellitus
- Stench—gangrene, necrotic lesion
- Fruity—after use of ether for GA
- Mousy—chronic liver dysfunction
- Bloody—internal hemorrhage

Exophytic lesion						
Condition	Appearance	Fluctuance	Entitbility	Usual history	Age	Frequency
Black hairy tongue	Patch of hairy growth on dorsal surface of tongue	No	No	Feels like hair on tongue gagging sensation	Older than 40	Occasionally
Mucocele	Nodular swelling	Yes	No	Variation in size rupture and draining	<40	Occasional
Ranula	Nodular swelling on floor of mouth	Yes	No	Slowly enlarging smaller in early morning	—	Common in female
Cavernous hemangioma	Nodular swelling	Usually not	Yes	Present from birth	—	Occasional
Early hematoma	Same	Yes	No	Recent trauma and bleeding disorder	—	Occasional
Superficial hematoma	Same	Yes	No	Displace teeth slowly enlarging	—	Occasional
Lymphangioma	Nodular swelling pebbly appearance	Usually not	Partially	Present from birth and after trauma	—	Rare
Mucoepidermoid tumor	Mucocele like nodule	—	No	Slowly expanding mass	40	Rare
Multiple neuro-fibromatosis	Café au lait spot ion skin and oral mucosa	—	no	Multiple skin tumor from birth	—	Rare
Rendu-Osler-Weber syndrome	Purple papule on skin and mucus membrane which blanch on pressure	No	Yes	Bleeding from lesion and body orifice	12	Rare

Generalized discoloration

Condition	Distribution	History	Age	Accompanied condition	Special test
Cyanosis	Total skin surface and oral mucosa	Increased severity in excretion	1 month to 2 years	Malaise dyspnea	Color decreased when oxygenated blood increased
Chloasma gravidarum	Skin face over the nose and cheek	Increased brownish color of skin	Older than 13	Pregnancy	—
Addison disease	Skin exposed	Hypoglycemia weakness decreased resistance to stress	18 and older	Adrenocorticoids insufficiency	–ve ACTH test
Hemochromatosis	Skin exposed	Slowly increasing, increased iron uptake multiple blood transfusion older than 35	Liver disease, diabetes, adrenal insufficiency	Test of skin liver bone marrow +ve for iron	
Argyria	Same	Chronic self-administer of silver containing	18 and over	Equilibrium and hearing problems headache	Skin positive for silver

Papillary or cauliflower like soft tissue growth of oral cavity

- Verrucous leukoplakia
- Verruca vulgaris
- Condyloma acuminatum
- Papilloma
- Keratoacanthoma
- Inflammatory papillary hyperplasia
- Verrucous carcinoma

- Fine needle
- Punch
- Scrape
- Trephine

Less commonly used

- Bite
- Brush
- Cone
- Core
- Endoscopic
- Irrigation
- Pressure
- Shave
- Sponge

Types of biopsy**Commonly used**

- Aspiration
- Curettage
- Excisional
- Incisional

Differential diagnosis of bullous—erosive mucosal changes				
Feature	<i>Pemphigus</i>	<i>Bullous pemphigoid</i>	<i>Mucous membrane pemphigoid</i>	<i>Erythema multiforme</i>
Age of the patient	Under 50 years	Over 60 years	Over 40 years	Any
Oral mucosal involvement	100%	20%	100%	50-60%
Initial oral lesion	70%	3%	85%	45%
Lethal effect without therapy	90-100%	10-15%	Under 1%	Under 1%
Tzanck test	+ve	–ve	–ve	–ve
Immunofluorescence	Intercellular	Basal membrane	Basal membrane	–ve

Tabular presentation of tooth tissue loss

Term	Definition	Clinical Appearance
Attrition	Loss by wear of surface of tooth or restoration caused by tooth to tooth contact during mastication or parafunction	• Matching wear on occluding surfaces • Shiny facets on amalgam contact • Enamel and dentin wear at the same rate • Possible fracture of cusps or restorations
Abrasion	Loss by wear of dental tissue caused by abrasion by foreign substance (e.g. tooth-brush, dentifrice)	• Usually located at cervical areas of teeth • Lesions are more wide than deep • Premolars and cuspids are commonly affected
Erosion	Progressive loss of hard dental tissue by chemical processes not involving bacterial action	• Broad concavities within smooth surface enamel • Cupping of occlusal surfaces, (incisal grooving) with dentin exposure • Increased incisal translucency, wear on non-occluding surfaces and raised amalgam restorations • Clean, non-tarnished appearance of amalgams • Loss of surface characteristics of enamel in young children • Preservation of enamel "cuff" in gingival crevice is common • Hypersensitivity and pulp exposure in deciduous teeth
Abfraction	Loss of tooth surface at the cervical areas of teeth caused by tensile and compressive forces during tooth flexure	• Affects buccal/labial cervical areas of teeth • Deep, narrow V-shaped notch • Commonly affects single tooth with excursive interferences or eccentric occlusal loads

Causes and mechanism of vitamin D deficiency

Predisposing factors	Mechanism
Dietary lack of meat and dairy product	Low levels of vitamin D in the diet
Lack of adequate exposure to ultraviolet light	Failure of vitamin D precursor synthesis in the skin
Gastric intestinal disease or chronic liver disease	Malabsorption of vitamin D and calcium
Aluminum toxicity and biphosphonates	Direct inhibition of bone mineralization
Administration of anticonvulsant drug like phenobarbitone	These drugs enhance liver enzyme activity which result in increase breakdown of vitamin D to biological inert product
Chronic renal failure	Reduced conversion of 25(OH)D ₃ to 1,25 (OH) ₂ D ₃
Hypophosphatemia rickets (X linked dominant)	Inherited defect in renal tubular phosphate reabsorption leading to hypophosphatemia
Hypophosphatasia (autosomal recessive)	Defect mutation in bone alkaline phosphatase which cause inhibition of bone mineralization at the calcification front

Radiological features of periapical cemental dysplasia

Stage	Appearance	Notes
Stage 1 Radiolucent (fibrous)	Identical to that seen in routine periapical rarefying osteitis	Vitality test of involved teeth is mandatory during this stage
Stage 2 Mixed stage	Minute radiopacities appear in the radiolucent periapical lesion	As this stage progress, the small radiopacities may coalesce The overall radiolucency usually does not enlarge further
Stage 3 Radiopaque (calcifying stage)	Substantial or complete opacification A radiolucent capsule (which may be very thin) always surrounds the opacity and separates it from the adjacent normal bone	The radiolucent capsule is of considerable diagnostic significance

Comparison of different clinical forms of histiocytosis-X				
Current designation	Former designation	Age of occurrence	Lesion distribution	Clinical course
Acute disseminated histiocytosis	Letterer-Siwe disease	Infancy and early childhood	Multiple lesion affecting bone, skin and other organs	Rapidly progressive often fatal; considered by many to be malignant neoplastic disease
Chronic disseminated idiopathic histiocytosis	Hand-Schuler-Christian disease	Children	Multiple bone lesion and extra-bony manifestation such as exophthalmos, diabetes insipidus, lymphadenopathy, splenomegaly, hepatomegaly, dermatitis	Gradual progression, lesion usually controlled by surgical removal and/ or low dose radiotherapy
Chronic localized idiopathic histiocytosis	Eosinophilic granuloma	Older children, adolescents and young adults	Isolate or multiple lesion limited to bone	Manifestation considered as either idiopathic inflammatory or benign neoplastic disease; usually controlled by surgical removal, although progression into the chronic disseminated form can occur

Different types of oral drug-reaction patterns and associated drugs	
Reaction	Drugs responsible
Xerostomia	Antidepressants and antipsychotics, antihypertensives, antihistamines, anticholinergics, and decongestants
Swelling	Penicillins, aspirin, and ACE inhibitors
Nonspecific ulceration	Antineoplastics, including methotrexate, 5-fluorouracil, doxorubicin, and melphalan; barbiturates; dapsone; phenazone derivatives; phenolphthalein; salicylates; sulfonamides; tetracycline; and (direct contact with) compounds containing aspirin, hydrogen peroxide, or phenol
Lichen planus-like	Allopurinol, amiphenazole, amphotericin B, antimalarials (chloroquine, hydroxychloroquine, quinacrine, quinidine), arsenicals, beta-blockers, bismuth, captopril, carbamazepine, chlorothiazide, chlorpropamide, cimetidine, cinnarizine, cyanamide, dapsone, fenclofenac, flunarizine, furosemide, gold salts, isoniazid, ketoconazole, levopromazine, levamisole, lithium, lorazepam, mercury, methylidopa, methopromazine, oxprenolol, palladium, para-aminosalicylic acid, penicillamine, phenothiazines, phenylbutazone, practolol, propranolol, pyrimethamine, pyritinol, spironolactone, sulfonylureas, streptomycin, tetracycline, tolbutamide, and triprolidine
Erythema multiforme-like	Antibiotics (antimalarials, penicillins, sulfonamides), barbiturates, and salicylates
Pemphigoid-like	Antirheumatics (penicillamine, ibuprofen, phenacetin), cardiovascular drugs (furosemide, captopril, clonidine), antibiotics (penicillins, sulfonamides), antimicrobials, thiol-containing drugs, and sulfonamide derivatives
Pemphigus-like	Alpha-mercaptopyrionylglycine, ampicillin, captopril, cephalixin, ethambutol, glibenclamide, gold, heroin, ibuprofen, penicillamine, phenobarbital, phenylbutazone, piroxicam, practolol, propranolol, pyritinol chlorohydrate, rifampin, and theobromine
Lupus-like	Carbamazepine, chlorpromazine, ethosuximide, gold, griseofulvin, hydantoins, hydralazine, isoniazid, lithium, methylidopa, penicillamine, primidone, procainamide, quinidine, reserpine, streptomycin, thiouracils, and trimethadione
Nonspecific vesiculoulcerative mucositis	Nonsteroidal anti-inflammatory drugs (NSAIDs) (i.e. indomethacin, gold salts, naproxen), meprobamate, methylidopa, penicillamine, phenylbutazone, propranolol, spironolactone, thiazides, and tolbutamide
Pigmentation	Amiodarone, antimalarials (chloroquine, hydrochloroquine, hydroxychloroquine, quinacrine, quinidine), busulfan, clofazimine, cyclophosphamide, estrogen, ketoconazole, minocycline, phenolphthalein, tranquilizers (chlorpromazine), and zidovudine
Gingival enlargement	Calcium channel blockers (amlodipine, bepridil, diltiazem, felodipine, isradipine, nicardipine, nifedipine, nimodipine, nisoldipine, nitrendipine, oxidipine, verapamil), other dihydropyridines (bleomycin), cyclosporine, phenytoin, and sodium valproate

Various drug reaction in oral cavity	
<i>Reaction</i>	<i>Drugs</i>
Xerostomia, or dry mouth	Antidepressants, antipsychotics, antihypertensives, antihistamines, and anticholinergics
Swelling	ACE inhibitors, penicillin and penicillin derivatives, cephalosporins, barbiturates, and aspirin and other NSAIDs
Osteonecrosis of the jaws	Bisphosphonate (bp) therapy
Gingival enlargement	Phenytoin, calcium channel blockers (members of the dihydropyridine class of medications), cyclosporine, and the antiepileptic drug sodium valproate within the calcium channel blocker family, nifedipine, diltiazem, verapamil, and amlodipine are among the most commonly reported causative agents
Pigmentation	Antimalarial agents, particularly chloroquine, hydroxychloroquine, quinacrine, and quinidine tranquilizers, especially chlorpromazine, zidovudine, clofazimine, and ketoconazole, Minocycline
Nonspecific vesiculoulcerative mucositis	Thiazide derivatives, naproxen, gold salts, and penicillamine
Lupus-like reactions	Procainamide and hydralazine
Pemphigus-like reactions	Thiol-containing drugs are the most common cause of pemphigus-like reactions
Pemphigoid-like reactions	Thiol-containing drugs and sulfonamide derivatives are among the most commonly involved medications, as are the therapeutic classes of Nsaids, cardiovascular agents, antimicrobials, and antirheumatics
Lichen-planus-like or lichenoid reactions	Antimalarial medications NSAIDs and ACE inhibitors
Erythema multiforme like reactions	Sulfonamides, sulfonylureas, and barbiturates
Nonspecific ulceration	Aspirin, hydrogen peroxide, potassium tablets, and phenol-containing compounds barbiturates, beta-blockers, dapsone, NSAIDs, phenazone derivatives

2

Syndromes of Oral Cavity

Adaptation Syndrome

- It is disease of hormone which respond to stimulation.
- Patient may suffer from hypertension, periarteritis nodosa and other hormone related disorders.

Adrenogenital Syndrome

- It occurs due to hyperplasia or tumors of renal cortex.
- Pseudohermaphroditism, sexual precocity and virilism in women or feminization in men.
- *Oral features*—premature eruption of teeth if the disease begins in early life.

Aglossia-Adactylia Syndrome

- Complete absence of tongue.
- Focal enlargement of salivary gland usually in hard palate area.

Albright's Syndrome

- It is also called as 'McCune-Albright syndrome'.
- Severe fibrous dysplasia involving nearly all bones of the skeleton.
- Pigmented lesions of the skin (*cafe' au lait* spots).
- *Endocrine disturbances*—hyper-function of one or more endocrine glands.

Aldrich's Syndrome

- It is also called as 'Wiskott-Aldrich' syndrome.
- It is characterized by thrombocytopenic purpura, eczema, and increased susceptibility to infection.
- *Oral features*—spontaneous bleeding from gingiva and palatal petechiae can be seen.

Amelo-onycho-hypohidrotic Syndrome

- Defective nails and hypofunction of the sweat glands. There is also seborrheic dermatitis.
- *Oral features*—severe hypoplastic hypocalcified enamel.

Anderson Syndrome

- It is also called as '*familial osteodysplasia*'.
- Craniofacial and skeletal anomalies.

- Presence of diastolic hypertension and hyperuricemia.
- Oral features include maxillary hypoplasia, reduced ramus, mandibular prognathism and malocclusion.

Angio-osteo-hypertrophy Syndrome

- Port-wine stain on the face, varices.
- Hypertrophy of bone including jaw bone.
- *Oral features*—facial asymmetry, malocclusion and altered eruption pattern of teeth.

Aortic Arch Syndrome

- It is also called as '*pulseless disease*'.
- It is caused by narrowing or obstruction of the major branches of the arch of the aorta.
- *General features*—dizziness, headache, visual disturbance and anginal pain.
- *Oral features*—there is tropic ulceration and pain while chewing. It is result from deficient blood supply to the muscle of mastication.

Apert's Syndrome

- It is also called as '*acrocephalosyndactyly*'.
- *Skeletal deformities*—there is syndactyly (fusion of finger) of second, third and fourth digit of hand and acrobrachycephaly (tower skull). In some cases kleeblattschadel deformity (cloverleaf skull). The skull is ovoid, brachycephalic and often presents a horizontal supraorbital groove.
- *Facial deformities*—the middle-third of face is undeveloped.
- *Oral features*
 - High palatal vault and V-shaped maxillary alveolar ridge.
 - Trapezoid shaped appearance of lip when lip are relaxed.
 - There is posterior palatal cleft and bifid uvula.
 - Retarded eruption and dental malocclusion.
- Class II malocclusion.

Ascher's Syndrome

- Patient is having a double lip.
- Blepharochalasis, i.e. drooping of the tissue between the eyebrow and the edge of upper eyelid.
- Non-toxic thyroid enlargement.

Auriculotemporal (Frey's) Syndrome

- It is caused by damage to auriculotemporal nerve.
- Flushing and sweating of the involved side of face, chiefly in temporal area, during eating.
- Gustatory sweating when eating spicy food.

B-K Mole Syndrome

- It is autosomal dominant condition.
- It is characterized by large pigmented nevi.
- There is high-risk of development of melanoma.

Baby Bottle Syndrome

- It is also called as 'nursing bottle caries' or 'bottle mouth syndrome'.
- It occurs due to habitual use of bottle usually as an aid for sleeping in night.
- There is wide spread carious destruction of deciduous teeth, most commonly the four maxillary incisors followed by the first molars and then the cuspids if habit prolonged.

Behçet's Syndrome

- *Recurrent oral ulceration*—it has similar appearance as aphthous ulcer.
- *Recurring genital ulceration*—ulcer of scrotum and penis in males and ulcers of labia in females.
- *Skin lesions*—they are manifested as large pustular lesions.
- *Ocular lesions*—it consist of uveitis, retinal vasculitis, optic atrophy, recurrent conjunctivitis and keratitis.

Beckwith's Hypoglycemic Syndrome

- *Macroglossia*—enlargement of the tongue.
- *Other features*—it includes neonatal hypoglycemia, mild microcephaly, umbilical hernia, fetal visceromegaly and postnatal somatic gigantism.

Bernard-Soulier Syndrome

- It is transmitted as autosomal dominant trait with variable penetration.
- The membrane receptors on platelets are absent and it accounts for bleeding problems.
- The bleeding time is prolonged.

Blepharochelodontic Syndrome

- It is transmitted as autosomal dominant inheritance.
- *Eye anomalies*—it includes lagophthalmus, ectropion of lower eyelid.
- *Lip*—there is bilateral cleft lip and palate.
- *Teeth*—oligodontia, microdontia including tiny molars.

Bloch-Sulzberger Syndrome

- Erythematous and vesiculobullous lesions on the trunk and extremities.
- These are replaced by white keratotic, lichenoid, papillary or verrucous lesions.
- Brownish gray macules in a streaked, patchy distribution over the trunk and extremities.

- *Oral features*—delayed tooth eruption, peg or cone shaped teeth, congenitally missing teeth, malformed teeth and additional cusps.

Blepharonasofacial Syndrome

- It is characterized by mental retardation, joint disorders and craniofacial anomalies.
- *Facial features*—affected individuals show microcephaly, an anti-mongoloid slant of palpebral fissures.
- *Oral features*—there is also hypoplastic maxilla, protruding lip and malocclusion resulting from midface hypoplasia.

Book's Syndrome

- Premature whitening of hair.
- Hyperhydrosis of palms and soles.
- *Oral features*—absence of the premolars and third molars.

Bowen Syndrome

- It is also called as 'cerebrohepatorenal syndrome'.
- Craniofacial anomalies, hypotonia, hepatomegaly and renal cortical cysts.
- *Oral features*—it includes micrognathia, protruding tongue and high arched palate.
- There is increase serum iron level and decrease in serum immunoglobulin levels.

Branchial Arch Syndrome

- It is heterogeneous group of malformation of the head and neck characterized by anatomic alteration in the structure which is derived from the branchial arches.

Burning Mouth Syndrome

- Pain and burning sensation in the mouth.
- Altered taste sensation and xerostomia.
- No clinically detectable lesions in the oral cavity.

Caffey-Silverman Syndrome

- It is also called as 'infantile cortical hyperostosis'.
- Development of tender deeply placed soft tissue swellings and cortical thickening or hyperostosis involving various bones of the skeleton.
- There is also pain, fever and irritability in infants.
- Increased serum levels of alkaline phosphatase and increased ESR.

Carotid Artery Syndrome

- Deviated styloid process or ossified ligament causing impingement on the internal or external carotid artery exerting pressure.
- There is atypical facial pain.

Candidosis Endocrinopathy Syndrome

- *Oral features*—chronic oral candidiasis and enamel hypoplasia.
- *Endocrine disorders*—it includes hypoparathyroidism, hypothyroidism, and hypo-adrenocorticism.
- *Metabolic disorders*—diabetes mellitus.

Carpenters Syndrome

- *Cloverleaf skull*—often associated with this defect is marked cranial asymmetry described as a “cloverleaf” skull anomaly caused by the craniosynostosis.
- *Eyes*—there is mild down sloping of the eyes, epicanthal folds, as well as malformations of the eyes themselves.
- *Ears*—the ears of these patients are low set, their necks are short.
- *Mandible*—mandible may be somewhat small.
- *High arched palate*—commonly seen in these patients is a highly arched and somewhat narrow palate.
- *Mental deficiency*—the mental deficiency seen with these patients varies from mild to severe, although multiple cases have been reported with normal intelligence.
- *Other*—tower shaped skull, presence of additional or fused fingers and toes, reduced height and obesity.

Cerebrocostomandibular Syndrome

- Thoracic deformity with barking cough and mental retardation.
- *Oral features*—it includes mandibular micrognathism, palatal defect and absence of uvula or even soft palate.

Carcinoid Syndrome

- Intermittent attack of flushing of skin of face.
- Watery diarrhea, abdominal pain, attacks of dyspnea.
- Right side heart failure due to involvement of tricuspid and pulmonary valve and endocardium.

Chediak-Higashi Syndrome

- It is transmitted as autosomal dominant trait.
- *General*—it includes oculocutaneous albinism, photophobia, nystagmus and recurrent infection of respiratory tract and skin.
- *Oral*—ulceration of the oral mucosa, severe gingivitis and glossitis.

Costen's Syndrome

- There is impairment of hearing, either continuously or intermittent.
- A stuffy sensation in the ears especially at mealtime.
- Tinnitus, otalgia, dizziness and headache about the vertex, occiput and behind the ears.
- Burning sensations in the throat, tongue and side of nose.

Cowden's Syndrome

- It is autosomal dominant disease characterized by facial trichilemmomas associated with gastrointestinal tract, central nervous system, thyroid and musculoskeletal abnormalities.
- Papillomatous lesion as well as ‘pebbly’ lesions of lip, gingivae, palate and pharynx occurs.
- Fibromas at various sites in the oral cavity.
- Lichenoid and papillomatous lesions of perioral, perinasal and periorbital areas of ear and neck.
- Hematoma of skin, gastrointestinal tract, breast and thyroid.

Cracked Tooth Syndrome

- Development of crack in a restored or unrestored tooth due to excessive occlusal force.
- Sharp pain on biting.

Cross Syndrome

- *Oral features*—it include gingival enlargement.
- *Other features*—it includes hypopigmentation, oligophrenia, microphthalmos and athetosis.

CREST Syndrome**Associated with scleroderma**

- C—Calcinosis cutis
- R—Raynaud's phenomenon
- E—Esophageal dysfunction
- S—Sclerodactyly
- T—Telangiectasia

Crouzon Syndrome

- It is also called as ‘craniofacial dysostosis’.
- *Cranial deformities*—protuberant frontal region with an anteroposterior ridge overhanging the frontal eminence and often passing to the roof of nose (triangular frontal defect). The cranium is brachycephalic.
- *Facial malformations*—there is hypoplasia of maxilla with mandibular prognathism.
- *Parrot beak*—the upper lip is short and nose resembles ‘Parrot's beak’.
- Oral feature includes high arched palate, V-shaped dental arch, peg shaped teeth and partial anodontia.
- *Eye changes*—hypertelorism, exophthalmos with divergent strabismus, optic neuritis and choked disc resulting frequently in blindness.
- *Others*—spina bifida occulta.

Cushing's Syndrome

- It is characterized by adiposity about the upper portion of the body, mooning of the face and tendency to become round shouldered.
- *Buffalo hump*—it is seen at the base of the neck.
- There is dusky plethoric appearance with formation of purple striae.
- There is also muscular weakness, vascular hypertension, glycosuria and albuminuria.
- *Children*—there may be osteoporosis and premature cessation of epiphyseal growth.

Curry-Hall Syndrome

- Short limbs, polydactyly and nail dysplasia.
- *Oral features*—deciduous teeth are small and conical. Incisors are retained as permanent successors may be congenitally missing.

Dejerine-Roussy Syndrome

- Tumors of the pons or occlusion of the posterior cerebral artery with sensory or motor abnormality on the contralateral side.
- *Oral features*—orofacial pain and dysgeusia are also present.

Down's Syndrome

It is also called as 'trisomy 21 syndrome' or 'mongolism'.

Systemic

- **Cardiovascular**—there is ventricular septal defect, ALV communication, patent ductus arteriosus and mitral valve prolapse.
- **Hematological features**—it includes impaired immuno-deficiency, short lived neutrophils, risk of lymphopenia, eosinophilia, increased risk of leukemia and increased risk of hepatitis carrier state.
- **Musculoskeletal**—it includes atlantoaxial instability; midface is underdeveloped with relative prognathism, narrow and partially obstructed nasal passage and open mouth with tongue thrusting habit.
- **Nervous**—motor function is delayed, dementia analogues and phonation distorted.
- **Behavior**—gentleness, anxiety and stubbornness.

Oral

- **Palate**—V-shaped high vault and soft palate insufficiency.
- **Oral opening**—angle of mouth is pulled down due to hypotonic musculature, lower lip is everted, mouth breathing with drooling of saliva, chapped lower lip and angular cheilitis.
- **Tongue**—scalloped or fissured tongue, protrusion with tongue thrusting, macroglossia and desiccated tongue.
- **Teeth**—microdontia, hypodontia, partial anodontia, supernumerary teeth, spacing, taurodontism, crown variation, agenesis, hypoplasia and hypocalcification and delayed eruption of teeth.
- **Occlusion**—malalignment, frequent malocclusion, frequent TMJ dysfunction and bruxism.

Eagle's Syndrome

- It is characterized by elongation of styloid process or ossification of stylohyoid ligament.
- **Features**—it includes dysphagia, sore throat, otalgia, glossodynia, headache and vague orofacial pain.

Edward's Syndrome

- It is also called as 'trisomy 18 syndrome'.
- The affected individuals are mentally retard and show hypertonicity.
- **Facial features**—there are small eyes and prominent occiput.
- The index finger overlaps the 3rd finger and 5th finger overlaps the 4th finger.
- **Oral features**—it includes micrognathia, high arched palate, cleft palate and bifid uvula.

Ehlers-Danlos Syndrome

- It is also called as 'rubber man' and is autosomal dominant.
- **General**—there is hyperelasticity of skin, hyperextensibility of joint and fragility of skin and blood vessels.
- **Oral features**—it includes enamel hypoplasia and periodontal destruction is severe. There is also hypermobility of TMJ resulting in repeated dislocation.

Elashy Water's Syndrome

- It is also called as 'brachioskeleto-genital syndrome'.
- There is mental retardation, brachycephaly face, divergent strabismus and ocular hypertelorism.
- **Oral features**—it includes cleft palate and multiple jaw cysts.

Ellis-van Creveld Syndrome

- It is also called as 'chondroectodermal dysplasia'. It is inherited as autosomal recessive trait.
- **Skeletal deformities**—the affected person is of short stature due to chondrodysplasia. Polydactyly is also reported.
- **Cardiac anomalies**—congenital heart disease may cause neonatal death.
- **Hair and nails defect**—nails are dystrophic. Eyebrows and pubic hair are often deficient.
- **Oral features**
 - Fusion of middle portion of the upper lip to maxillary gingival margin eliminating the normal upper labial sulcus.
 - Deciduous teeth show hypoplasia and permanent tooth eruption is delayed.
 - Accessory cusp is common.

Epidermis Nevus Syndrome

- Cutaneous nevi extending upto oral mucosa and gingiva.
- Mental deficiency, skeletal abnormality.
- There is also presence of hypoplastic teeth.

Fanconi's Syndrome

- Congenital or familial aplastic anemia.
- Bone abnormalities, microcephaly and generalized olive-brown pigmentation of the skin.

Favre-Racouchot Syndrome

- It occurs due to ultraviolet light and excessive smoking habit.
- There is extensive sun damage of the facial skin.
- There are also numerous open, dilated and cystic comedones.
- Dermis show solar elastosis characterized by dilated pilosebaceous opening with distended, horn filled hair follicle.

First Arch Syndrome

- **Oral features**—it includes cleft lip and palate and mandibulofacial dysostosis.
- Hypertelorism and deformities of ear.

Floppy Infant Syndrome

- Generalized weakness due to hypotonia.
- Inability to sit, stand and walk.
- Hypotonia may involve tongue and facial muscles.

Fragile X Syndrome

- X-linked mental retardation, macro-orchidism and large ears.
- Long narrow face and cleft palate.
- Mitral valve prolapsed.

Focal Dermal Hypoplasia Syndrome

- Focal absence of dermis associated with herniation of subcutaneous fat into the defects.
- Skin atrophy, streaky pigmentation, telangiectasia.
- Multiple papilloma of skin or mucosa, syndactyly, polydactyly and adactyly.
- Asymmetrical face with pointed chin and notched nasal alae, papillomas present on lips, buccal mucosa and gingiva.
- Microdonia with defect in size of teeth.
- Enamel hypoplasia, cleft lip/cleft palate.

Franceschetti's Syndrome

- Antimongoloid palpebral fissure with colobomas of the outer portion of the lower eyelids and deficiency of eyelashes.
- Hypoplasia of facial bone especially malar bone mandible.
- Malformation of external ear and middle ear.
- High palate and malocclusion is also present.
- Blind fistulae between angle of the ears and angle of mouth.
- Typical hair growth in form of tongue shape extending towards the cheek.
- Bird like or fish like appearance.

Gardner's Syndrome

- *Systemic features*—multiple polyposis of large intestine and polyp of colon and rectum.
- *Tumors*—osteomas of bone including long bones, skull and jaws. There may be occasional occurrence of desmoid tumors. Other tumors which can occur are lipoma, leiomyoma and adenocarcinoma of colon.
- *Cysts*—multiple epidermoid or sebaceous cyst of skin particularly of scalp and back.
- *Oral features*—hypercementosis, multiple unerupted supernumerary teeth and compound odontoma.

Gilles de la Tourette's Syndrome

- Spontaneous erratic behavior of the patients.
- Incoherent facial expressions and verbalization.
- Tendency for self-mutilation of oral tissue by use of teeth and finger nails.

Goltz-Gorlin Syndrome

- It is also called as 'focal dermal hypoplasia syndrome'. It is transmitted as an autosomal dominant trait.
- *General features*
 - Focal absence of dermis associated with herniation of subcutaneous fat into the defects.
 - There is also skin atrophy, streaky pigmentation and telangiectasia.
 - Multiple papillomas of skin or mucosa.
 - Syndactyly, polydactyly, and adactyly.
- *Oral features*—papillomas of lip, microdonia, cleft lip and cleft palate.

Gorlin-Chaudhry-Moss Syndrome

- It is characterized by craniofacial dysostosis, patent ductus arteriosus, hypertrichosis and hypoplasia of labia majora.
- Oral feature of this syndrome is hypodontia.

Goldenhar's Syndrome

- Unilateral microstomia, mental retardation, hypoplastic zygomatic arch.
- *Facial features*—there is downward slanting of palpebral fissures, malformed pinna and iris coloboma.
- *Oral features*—there is high arched palate, palatal and uvular cleft with malocclusion.

Gorham's Syndrome

It also called as 'massive osteolysis' or 'Phantom bone'.

- Osteolysis of single or multiple bones followed by replacement with fibrous tissue.
- Pain in the bone and pathological fractures.
- *Oral features*—there may be destruction of mandible or maxilla. Pain and facial asymmetry can be seen.

Graham Little Syndrome

- It combines small confluent patches of progressive scarring alopecia resembling that of lichen planus follicularis.
- There is also follicular keratosis, and non-cicatricial alopecia of the axilla and pubes.
- Patches on the scalp are atrophic and cicatricial in the center but erythematous and squamous around the edges, where follicular keratosis occurs when the disease is actively progressing.

Grinspan Syndrome

- It is triad of lichen planus, diabetes mellitus and vascular hypertension.

Gradenigo's Syndrome

- Suppurative otitis
- Trigeminal nerve pain
- Abducens nerve palsy

Hajadu Cheney Syndrome

It is rare autosomal dominant disorder characterized by short stature, disintegration of terminal phalanges of fingers and toes.

- *Facial features*—long nose, low frontal hairline and flared ears.
- *Skeletal feature*—the individual is usually victim of multiple fractures of bones. Sutures are usually open and frontal sinuses are absent.
- *Oral features*—there is premature loss of teeth and abnormal shape of skull.

Hanhart's Syndrome

- *Digital deformities*—it includes oligodactyly, syndactyly and hypoplastic digits.
- *Oral features*—there is micrognathia, microglossia and hypodontia.

Hallermann-Streiff Syndrome

- *Skeletal and genital*—it includes syndactyly and hypogenitalism.
- *Facial features*—it includes microphthalmia, long thin tapering nose, strabismus, and double cutaneous chin with central furrow, hypotrichosis of the scalp and eyebrows and prominent scalp veins.

- *Oral features*—it includes hypodontia, microstomia, malocclusion, malformed teeth and retained deciduous teeth.

Heerfordt's Syndrome

- Firm painless, bilateral enlargement of parotid gland.
- Inflammation of uveal tract of the eye.
- Facial palsy.

Hetch-Beals-Wilson Syndrome

- Limited mandibular opening.
- Shortened leg, hamstring muscles and club foot.

Horner's Syndrome

- Miosis or contraction of pupil of the eye due to paresis of dilators of pupil.
- Ptosis or drooping of eyelid due to paresis of smooth muscle elevators of upper lid.
- Anhidrosis and vasodilatation over the face due to interruption of sudomotor and vasomotor control.

Horton's Syndrome

- It is also called as '*sphenopalatine neuralgia*'.
- Unilateral paroxysms of intense pain in the eye, maxilla, ear, mastoid region, base of nose and beneath the zygoma.
- Absence of trigger zones and occurrence of pain everyday exactly at the same time- for this reasons it is called as '*alarm clock headache*'.

Hurler's Syndrome

- It is disturbance in mucopolysaccharide metabolism.
- *Facial features*—prominent forehead, broad saddle nose, wide nostrils, hypertelorism and puffy eye lids. There is also corneal clouding present.
- There is also nasal congestion with noisy breathing.
- '*Claw hand*' resulting from flexion contractures.
- Hepatosplenomegaly results in protuberant abdomen.
- Death usually occurs before the age of 10 years.
- *Oral features*—thick lips, large tongue, open mouth.

Hunter's Syndrome

- Similar feature like Hurler's syndrome but they are mild.
- Corneal clouding is absent.
- Death usually occurs before the age of 15 years.

Hutchinson-Gilford Syndrome

- It is also called as '*progeria*'. It is transmitted as autosomal dominant trait. There is manifestation of old age features, pro- before, geria- old.
- Alopecia, pigmented areas of trunk, atrophic skin, prominent vein and loss of subcutaneous fat.
- The individual has high pitched, squeaky voice and beak-like nose.
- *Oral features*—loss of all teeth in very young age, hypoplastic mandible, and delayed eruption of teeth can also occur.

Hypoglossia-hypodactylia Syndrome

- Total or partial absence of the tongue.
- Micrognathia, high arched or cleft palate, glossopalatine ankylosis, defects in the lower lip and hypertrophy of sublingual glands.
- Hypodactylia and hypomelia.

Jaw-Winking Syndrome

- It is also called as '*marcus gun phenomenon*'.
- Rapid elevation of the ptotic eyelid occurring on movement of the mandible on the contralateral side.
- Congenital unilateral ptosis.

Jadassohn-Lewandowsky Syndrome

- Bilateral oral white lesions involving the tongue and buccal mucosa.
- Laminated thickening of fingers and toe nails.

Jaw Cyst-Basal Cell Nevus-Bifid Rib Syndrome

- It is also called as '*Gorlin-Goltz syndrome*'.
- *Cutaneous anomalies*—basal cell carcinoma, dermal cysts and tumors, palmar pitting, palmar and plantar keratosis and dermal calcinosis.
- *Dental abnormalities*—odontogenic keratocysts and mild mandibular prognathism.
- *Osseous abnormalities*—bifid rib, vertebral anomalies and brachy-metacarpalism.
- *Ophthalmologic anomalies*—hyper-telorism with wide nasal bridge, dystopia canthorum, congenital blindness and internal strabismus.
- *Neurological anomalies*—mental retardation, agenesis of corpus callosum, ductal calcification, congenital hydrocephalus and medulloblastomas.
- *Sexual anomalies*—hypogonadism, ovarian tumors.

Jugular Foramen Syndrome

- Dysphagia, hoarseness of voice, glossopharyngeal neuralgia like pain.
- Palatal weakness and vocal cord paralysis.

Kartagener's Syndrome

- Bronchiectasis
- Situs in versus
- Sinusitis

KBG Syndrome

- The affected individual show short stature and mental retardation.
- *Facial features*—flat bridge of nose, round face, long philtrum and abnormal auricle, with or without hearing defect.
- *Oral features*—include macrodontia, oligodontia, hypoplasia of enamel and micrognathia.

Klinefelter's Syndrome

- It occurs in males whose sex chromosome constitution includes one or more extra chromosomes.
- The patient develops infertility and gynecomastia.

- There may be fatigue, osteoporosis, mitral valve prolapse and varicose veins.
- The patients develop taurodontism.

Klippel-Trenaunay-Weber Syndrome

- *Hemangioma*—hemangioma of facial region.
- *Ocular lesion*—bluish, thin sclera, glaucoma.
- *Neurological symptoms*—epilepsy, mental retardation.
- *Oral finding*—gingival enlargement can be present.

Larsen's Syndrome

- It is an autosomal dominant disorder.
- There is prominent forehead with frontal bossing, flattened midface, depressed nasal bridge and hypertelorism.
- There is bilateral anterior dislocation of tibia or femur with displaced patella.
- *Oral features*—it includes cleft palate and malocclusion.

Laugier-Hunziker Syndrome

- Acquired pigmented macules in the lips, oral cavity and fingers.

Lowe's Syndrome

- Generalized aminoaciduria, mental retardation, hypotonia, congenital cataracts.
- Abnormal skull shaped.

Maffucci's Syndrome

- Multiple chondroma of the jaw bone.
- Multiple hemangiomas of skin and oral mucosa. Phleboliths can also occur.
- In oral mucosa, it occurs on the tongue.

Marfan's Syndrome

- *Skeletal*—excessive length of tubular bone resulting in disproportionate long thin extremities.
- *Craniofacial*—skull and face are long and narrow. Ears are large, eyes appear sunken and frontal bossing is seen.
- *Ocular*—ocular lens subluxation with a defect in the suspensory ligament.
- *Cardiovascular*—aortic aneurysm and regurgitation.
- *Oral*—temporomandibular joint dysarthrosis, multiple odontogenic cysts of maxilla and mandible, high arched palate and bifid uvula.

Magic Syndrome

- Mouth and genital ulcers with inflamed cartilage.

Marin Amat's Syndrome

- It is also called as '*inverted marcus gun phenomenon*'.
- Eye closes automatically when patient opens his mouth forcefully and fully, tears may also follow.

Melnick-Needles Syndrome

- It is autosomal dominant condition characterized by generalized bony dysplasia and abnormal facies.

- There is marked exophthalmos, full cheeks and large ears.
- *Oral features*—micrognathia, transversely long mouth and malocclusion.
- *Skeletal*—delayed closure of anterior fontanelle, defect in clavicles, ribs and vertebrae.

Median Cleft Face Syndrome

- It is also called as '*frontonasal dysplasia*'.
- There is nasal clefts and notches, preauricular tags and ocular hypertelorism.
- There is also median cleft of premaxilla and palate and malocclusion.

Melkersson-Rosenthal Syndrome

- It is triad of cheilitis granulomatosa, facial paralysis and scrotal tongue.

Miescher's Syndrome

- It is also called as '*cheilitis granulomatosa*'.
- Diffuse swelling of lip especially lower lip.
- Scarring, fissuring, vesicle or pustule formation on the vermillion border.
- It is associated with Melkersson-Rosenthal syndrome.

Middle Fossa Syndrome

- It occurs due to tumor in the region of gasserian ganglion.
- There is hyperesthesia, paraesthesia and paralysis of ocular muscles.
- Deviated mandibular opening and unilateral soft palate paralysis.

Mobius Syndrome

- It is also called as '*congenital facial diplegia*'.
- In infancy, failure to close the eyes during sleep.
- Partial/complete facial paralysis results in no change in facial expressions while crying or laughing.
- Drooling of saliva and difficulty in mastication.
- There is also external ophthalmoplegia, deformity of external ear, deafness, defect of pectoral muscle, paresis of tongue, soft palate or jaw muscles, clubfoot, mental defects and epilepsy.

Mohr's Syndrome

- It is autosomal recessive disorder characterized by several oral, facial and digital defects. The affected individual is moderately short.
- *Digital deformities*—brachydactyly, syndactyly or polydactyly.
- *Facial deformities*—midline cleft lip and bifid tip of nose.
- *Oral features*—there is high arched palate, lobate tongue, hypoplastic body of the mandible and hypodontia.

Morquio's Syndrome

- Severe enamel hypoplasia with grey and pitted enamel.
- Severe bone changes, corneal clouding and aortic regurgitation.

Multiple Endocrine Neoplasia Syndromes**MEN 1**

- Tumor or hyperplasia of pituitary; parathyroid gland, adrenal cortex and pancreatic islets.
- There is also peptic ulcer and gastric hypersecretion.

MEN 2 (Sipple's syndrome)

- Parathyroid adenoma or hyperplasia but no tumor of pancreas.
- Pheochromocytomas of adrenal medulla and medullary carcinoma of thyroid gland occurs.

MEN 3**Systemic**

- Mucocutaneous neuromas, pheo-chromocytomas of adrenal medulla and medullary carcinoma of thyroid.
- *Marfanoid habitus*—it refers to a slender body build, with long, thin extremities and increased laxity of joints. The face appears long and thin.

Oral

- Neuromas of lip, tongue and buccal mucosa.
- Thick and bumpy lips and infrequent prognathism.

Murray Puretic-Dresher Syndrome

- Gingival fibromatosis.
- Multiple hyaline fibromas of head, trunk and extremities.
- Suppurative skin lesions and flexion contractures.

Mucocutaneous Lymph Node Syndrome

- Bilateral congestion of ocular conjunctive and edema of extremities.
- Dryness and fissuring of the lips.
- Strawberry like redness and swelling of tongue.
- Acute non-purulent swelling of the lymph nodes.

Myofascial Pain Dysfunction Syndrome

- Pain in the muscle, muscle tenderness of masticatory muscle.
- Clicking or popping noise in temporomandibular joint and limitation of jaw motion.

Nance-Horan Syndrome

- X-linked congenital cataract.
- Supernumerary teeth.
- Incisor teeth can resemble Hutchinson's incisor.

Nager's Syndrome

- It is also called as '*acrofacial dysostosis*'.
- *Facial features*—there is hypoplasia of malar bones, anti-mongoloid obliquity or palpebral fissures. Also absent eyelashes, deformed ears, defective hearing, syndactyly and abnormalities of humerus and radius.
- *Oral features*—orally, there is cleft palate, micrognathism and malocclusion.

Neck-tongue Syndrome

- Unilateral upper nuchal or occipital pain, with or without numbness in the area.
- Simultaneous numbness of the tongue on that side.

Noonan's Syndrome

- Congenital heart disease, chest deformity and mental retardation.
- Short stature, facial bone anomalies and cryptorchidism.

Orofacial Digital Syndrome

- It is X-linked condition which is exclusively found in females.
- *Facial features*—it includes frontal bossing, hypoplasia of alar cartilages, broad nasal root, and ocular hypertelorism.
- *Digital malformation*—it includes clinodactyly, syndactyly, brachydactyly and polydactyly.
- *Oral features*
 - Cleft tongue, cleft of alveolar process (mandibular) and cleft lip.
 - Thick fibrous bands in the lower mucobuccal fold eliminating the sulcus.
 - Supernumerary canine and premolars.
 - Malposition teeth.

Oromandibular Limb Hypogenesis Syndrome

- *Eye lesion*—it consist of ocular hypertelorism.
- *Nerve lesion*—it includes cranial nerve palsy.
- *Hypodactyly*—absence of digit of hands and feet.
- *Hypomelia*—hypoplasia of part of limb.
- *Oral features*—there is hypoglossia, microstomia, cleft palate, ankyloglossia, micrognathia and conical shaped mandibular incisors.

Otopalatodigital Syndrome

- It is also called as '*OPD*' syndrome.
- *General*—affected individuals are mentally subnormal, occasionally deaf and there is generalized bone dysplasia.
- *Facial features*—prominent supraorbital ridge, apparent hypertelorism and frontal bossing.
- *Oral features*—there is cleft palate, micrognathic mandible and genital angle is obtuse.

Papillion-lefevre Syndrome

- Juvenile periodontitis, gingival ulcers, inflammatory gingival enlargement and formation of pockets.
- Palmar plantar hyperkeratosis.
- Generalized hyperhydrosis and dirty colored skin.

Para-trigeminal Syndrome

- Severe headache or pain in the area of trigeminal distribution with signs of ocular and sympathetic paralysis.

Patau's Syndrome

- It is also called as '*trisomy 13 syndrome*'.

- The affected individuals may show polydactyly and heart anomalies.
- *Facial features*—it includes microcephaly, microphthalmia, ocular hypertelorism and deafness.
- *Oral features*—it includes cleft lip and cleft palate.
- Polydactyly and heart anomalies.

Parry-Romberg Syndrome

- It is also called as '*progressive hemifacial atrophy*' characterized by unilateral atrophy of face.
- There is also atrophy of skin, subcutaneous tissue, muscle and bone.
- Loss of hair and vitiligo can be seen.
- Contralateral jacksonian epilepsy and trigeminal neuralgia also occur.
- *Oral features*—atrophy of half of the tongue and retarded dental eruption on the involved side.

Peutz-Jeghers Syndrome

- It is also called as '*hereditary intestinal polyposis syndrome*'.
- There is familial generalized intestinal polyposis.
- Pigmentation of face, oral cavity and sometimes on hands and feet.
- There may gastric, duodenal and colonic adenocarcinoma.

Pfeiffer Syndrome

- *Skeletal deformities*—it includes craniosynostosis with turri-brachycephaly, broad thumbs and halluces.
- *Facial deformities*—midface hypoplasia, shallow orbit, hypertelorism, proptosis and antimongoloid obliquity.
- *Oral features*—it includes maxillary underdevelopment resulting in mandibular prognathism, high arched palate and bifid uvula.

Pierre Robin Syndrome

- There is U-shaped cleft palate, micrognathia and glossoptosis.
- Occasionally hydrocephaly or microcephaly can be seen.

Plummer-Vinson Syndrome

- Cracks or fissures at the corner of mouth (angular cheilitis).
- Dysphagia due to esophageal webs.
- Atrophy of filiform papillae and koilonychia.

Portsmouth Syndrome

- Normal ADP-induced platelet aggregation but abnormal or absent collagen induced aggregation.
- It is associated with thrombocytopenia purpura.

Popliteal Pterygium Syndrome

- Congenital lip pit.
- Popliteal webbing (pterygia).
- Cleft lip/cleft palate.
- Genital abnormalities.
- Congenital bands connecting the upper and lower jaws (syngnathia).

Proteus Syndrome

- *Skull features*—hemihypertrophy of the skull, seldom of other bones of the facial skeleton.
- *Partial gigantism*—partial gigantism especially of hand and/or feet, asymmetric limb overgrowth and length discrepancy.
- *Scoliosis*—scoliosis of the vertebral column.
- *Other features*—hyperostosis, various tumors, lipoma, lymphangioma, connective-tissue nevi, and vascular malformations
- *Teeth features*—late mixed dentition with an unusual asymmetric dental development and eruption and crowding with loss of space in teeth.

Raeder's Syndrome

- It is also called as '*paratrigeminal syndrome*'.
- Headache or pain in the area of trigeminal distribution.
- Ocular sympathetic paralysis.

Ramon's Syndrome

- Hypertrichosis, epilepsy and mental retardation.
- Gingival fibromatosis and cherubism.

Raley-day Syndrome

- Congenital absence of tongue papillae.
- Vasomotor dysfunction, loss of reflexes and feeding problems.
- Lack of pain and taste sensation.

Ramsay Hunt Syndrome

- Zoster infection of geniculate ganglion with involvement of external ear and oral mucosa.
- Facial paralysis, pain of external auditory meatus and pinna of the ear.
- Vesicular eruptions in the oral cavity and oropharynx with hoarseness, tinnitus, and vertigo.

Reiter's Syndrome

- *Urethritis*—urethral discharge is associated with itching and burning sensation.
- *Arthritis*—it often bilaterally symmetrical and usually polyarticular.
- *Conjunctivitis*—it is often mild.
- *Mucocutaneous lesions*—they are similar to blennorrhagia and consist of red or yellow keratotic macules or papules which eventually desquamate.
- *Oral features*—there is recurrent oral ulcerations.

Rieger's Syndrome

- *Facial*—there is broad nasal root, protruding lower lip.
- *Ocular findings*—it includes blue sclera, aniridia glaucoma and microcornea hypoplasia.
- *Oral features*—it includes hypodontia, enamel hypoplasia, maxillary hypoplasia, malformed anterior teeth and microdontia.

Rutherford's Syndrome

- Congenital enlargement of the gingivae and altered eruption of teeth.
- There is corneal dystrophy, conjunctivitis and mucocutaneous lesion.

Rubinstein-Taybi Syndrome

- It is associated with *talon's* cusp.
- Developmental retardation, broad thumb and great toes.
- Delayed or incomplete descent of testes in males.

Sanfilippo's Syndrome

- Severe CNS defect, mild somatic disturbance.
- Enamel hypoplasia and excessive dentinogenesis with obliteration of pulp chambers.

Saethre-Chotzen Syndrome

- It is an autosomal dominant trait characterized by short stature and mild mental retardation.
- *Facial deformities*—it includes ocular hypertelorism, ptosis of eyelids, deviated nasal septum and mild conductive deafness.
- *Other deformities*—finger exhibits cutaneous syndactyly and occasional renal abnormalities can be seen.
- *Oral features*—it includes prognathism, high arched palate and resultant malocclusion.

Scheie's Syndrome

- Stiff joints, corneal clouding, aortic regurgitation and normal intelligence.

Scalded Skin Syndrome

- Mild bullous drug eruption resulting in peeling off large sheet of skin giving the appearance of scalding burn.

Scheuthauer-Marie-Sainton Syndrome

- It is also called as '*cleidocranial dysplasia*'.
- Open fontanelle of skull and partial or complete absence of clavicles.
- Underdeveloped maxilla, multiple impacted or unerupted, permanent or supernumerary teeth.

Senear-Usher Syndrome

- Bulla and vesicle on skin and oral mucosa.
- Nikolsky's sign is positive.
- This lesion is terminated in pemphigus vulgaris or foliaceus.

Sjögren's Syndrome

- *Primary*—keratoconjunctivitis sicca and xerostomia.
- *Secondary*
 - Keratoconjunctivitis sicca and xerostomia.
 - Lupus erythematosus, polyarteritis nodosa, scleroderma and rheumatoid arthritis.

Stevens-Johnson Syndrome

- *Oral mucus membrane lesions*—severe form of erythema multiforme.

- *Eye lesions*—photophobia, conjunctivitis, corneal ulceration.
- *Genital lesions*—nonspecific urethritis, balanitis, or vaginal ulcers.

Sturge-Weber Syndrome

- Angiomatosis of face (nevus flammeus) and leptomeningeal angiomas.
- There is also intracranial calcifications and contralateral hemiplegia.
- Massive growth of gingiva and asymmetrical jaw growth and tooth eruption sequence.

Sweat Retention Syndrome

- Extravasation of sweat or saliva in the tissue with subsequent inflammation.
- Keratin plugs formation in sweat glands and accessory salivary glands.

Sweet Syndrome

- Fever.
- Relative increase of neutrophils in the peripheral blood.
- Skin lesion such as tender erythematous plaque, nodules, vesicle and pustules on the face and extremities.
- Dense dermal infiltrate with mature neutrophils.
- Intraoral ulceration is also seen.

SUNCT Syndrome

- S—short acting
- U—unilateral
- N—neuralgiform headache
- C—conjunctival infection
- T—tearing

Treacher Collins Syndrome

- It is also called as '*mandibulofacial dysostosis*' and is autosomal dominant.
- *Facial features*
 - Downward sloping of palpebral fissures (antimongoloid obliquity), under-developed cheek bone, receding chin and malformation of external ear.
 - Hypoplasia of facial bone, especially of malar bone and mandible.
 - Blind fistulae between angle of mouth and angle of ear.
 - Facial clefts and skeletal deformities.
- *Oral features*—fish like mouth, macrostomia, high arched palate, malocclusion, pronounced concavity of the under-surface of the mandible and an obtuse mandibular angle.

Trotter's Syndrome

- Carcinoma of nasopharynx often producing trigeminal neuralgia like pain in the mandible, tongue and side of the head.
- There is also middle ear deafness.

Trichodental Syndrome

- Inherited dominant condition and is characterized by fine short hair.

- Thinning of lateral end of eyebrows.
- Hypodontia and conical teeth.

Trichodentoosseous Syndrome

- It is transmitted as an autosomal dominant trait.
- *Hair and nail deformities*—it includes kinky hair and nails show white band and are brittle.
- *Oral features*—it includes hypomaturation type of amelogenesis imperfecta, enamel hypoplasia, unerupted teeth and taurodontism. The mandibular angle is obtuse and the jaw is square.

Trichonychodental Syndrome

- It is autosomal dominant trait.
- Fine curly hair and thin dysplastic nails.
- *Oral features*—taurodontism and developmental defect of enamel and dentin.

Turner's Syndrome

- Short stature, cabitus vulgus, webbed neck, renal disorders and sexual infantilism.
- *Oral features*—it includes micrognathia, high arched palate and corners of mouth appear pulled down. There is premature eruption of teeth.

Tuberous Sclerosis Syndrome

- *Oral*—gingival lesions and enamel hypoplasia.
- *Skin*—adenoma sebaceum.
- *Associated anomalies*—epilepsy, mental retardation and hamartomas of brain, heart and kidney.
- *Associated malignancy*—astrocytoma and glioblastoma.

van der Woude's Syndrome

- Occurrence of pits of lower lip
- Presence of cleft lip and cleft palate.

Van Buchem's Syndrome

- Excessive deposition of endosteal bone throughout the skeleton.
- Facial swelling and occasional facial paralysis.

Velocardiofacial Syndrome

- *Synonym*—it is also called as Shprintzen Syndrome, Craniofacial Syndrome, or Conotruncal Anomaly Face Syndrome. The name Velocardiofacial Syndrome comes from the Latin words “velum” meaning palate, “cardia” meaning heart, and “facies” means facial features.
- *Cleft palate*—cleft palate (incomplete closure of the roof of the mouth).
- *Heart defect*—multiple abnormalities of the heart including Ventricular septal defect (VSD), pulmonary atresia, tetralogy of Fallot, truncus arteriosus, interrupted or right-sided aortic arch and transposition of the great arteries.

- *Facial features*—there is long face with prominent upper jaw, flattening of the cheeks and underdeveloped lower jaw. There is also prominent nose with narrow nasal passages and thin upper lip with a down-slanted mouth.
- *Other features*—minor learning problems, speech and feeding problems, bluish color below the eyes can also be present.

von Recklinghausen's Neurofibromatosis

- *Oral lesions*—intraoral neurofibromas leading to macroglossia.
- *Skin lesion*—café au lait spots, giant nevi and multiple neurofibromas.
- *Malignancy*—malignant neurilemmoma and pheochromocytomas.
- *Neurological*—CNS tumor, mental retardation.

von Hippel's Syndrome

- Hemangioblastomas in retina and cerebellum.
- Pancreatic and renal cyst, renal adenomas and hepatic hemangioma.
- Multiple endocrine neoplasms.

Whistling Face Syndrome

- It is also called as ‘*craniocarpotarsal dysplasia*’.
- It is characterized by sunken eyes, true ocular hypertelorism and antimongoloid obliquity of palpebral fissures.
- It also includes small nose, microstomia, high skull and protruding lips as seen during whistling.
- The palate is high arched and mandible is small and retrognathic.
- There is presence of a fibrous band demarcated by two grooves extending from the midline of the lower lip to the chin, often presenting in ‘H’ or ‘V’ shaped.

Weber Cockayne Syndrome

- It is localized form of epidermolysis bullosa.
- Bullae develop on hand and feet and are related to frictional trauma.
- There is no scarring upon healing.

XXXXY Syndrome

- There is hypoplastic midface, short stature, mental retardation, speckled eyes and hypertelorism.
- *Oral features*—it includes taurodontism and bifid uvula.

Zimmerman-Laband Syndrome

- Gingival fibromatosis and ear, nose and nail defect.
- Hepatosplenomegaly and hyperextensible joint.

Zinsser's Syndrome

- Oral leukoplakia, dystrophic nails and hyperpigmentation of skin.
- Pancytopenia and aplastic anemia.

3

Glossary

Aberration—it is a variation from the normal form or course.

Aberrancy—it is defined as that situation in which a tissue develops at a site where it is not normally found.

Ablation—it is removal of a part by excision or amputation.

Abnormal—it is not normal, deviating in some from the usual structure, position or state.

Abocclusion—it is a condition where the maxillary and mandibular teeth are not in contact.

Abrasion—it is the wearing away of a structure or substance by mechanical means such as scrubbing or grinding.

Abrasive—it is a substance which contains an abrasive which tends to erode the surface.

Abfraction—loss of tooth surface at the cervical areas of teeth, caused by tensile and compressive forces during tooth flexure; cervical erosive lesions that can not be attributed to any particular cause.

Abscess—an abscess is a localized collection of pus surrounded by an area of inflamed tissue in which hyperemia and infiltration of leukocytes is marked.

Actinic keratosis—it is a premalignant squamous cell lesion resulting from long-term exposure to solar radiation and may be found on the vermillion border of lip as well as other sun exposed skin surfaces.

Actinic elastosis—it is a lesion on the labial mucosa exposed to sun. A white area of atrophic epithelium develops with underlying scarring of the lamina propria.

Actinic cheilitis—when this atrophic tissue abrades to ulcer, it is called as actinic cheilitis.

Acanthosis—this condition is characterized by widening and thickening of stratum spinosum.

Acantholysis—it is the pathological separation of epidermal or epithelial cells by breakdown of desmosomes in stratum spinosum (seen in pemphigus).

Acquired—relating to something not of genetic origin but resulting from outside influence.

Acrocephalic—it is a highly arched or pointed skull.

Acute—having severe symptoms and a short course.

Adduction—drawing in towards the center or to median line, as opposed to abduction.

Adenomatosis oris—it is the swelling of the mucous glands of the lips with no inflammation or secretion.

Adrenodontia—it is a morphological indication of over activity of adrenal glands characterized by large pointed canines and teeth with occlusal surfaces showing brown discoloration.

Aerodontia—it is that branch of dentistry concerned with the care and treatment of dental conditions caused by high altitude flying.

Afferent nerve—it refers to any nerve transmitting impulse from the periphery to the center.

Ageusia—it is the loss or absence of sense of taste.

Aglossostomia—it is the congenital absence of the tongue and of mouth opening.

- Agranulocytosis**—a marked decrease in the number of granulocytes, particularly neutrophils.
- Allograft**—a graft using material not derived from a donor or from animal sources, e.g. synthetic resins, stainless steel alloy.
- Allergen**—a substance capable of inducing hypersensitivity or an allergic reaction.
- Allergy**—it is hypersensitivity to any normally harmless substance resulting in an exaggerated or abnormal reaction.
- Allograft**—it is a graft derived from a donor of the same species but genetically dissimilar.
- Amniocentesis**—it is diagnostic procedure in which a small amount of amniotic fluid is withdrawn from amniotic sac, a membrane surrounding the fetus in uterus, to detect fetal defects.
- Amalgam tattoo**—oral soft tissue discolorations due to amalgam; most common pigmentation of the oral cavity.
- Amelogenesis**—the formation of the enamel portion of the tooth.
- Analgesia**—it is relief from pain or insensibility to pain.
- Analogous**—having similar properties.
- Anesthesia**—it is the general loss of all sensations or feelings.
- Anemia**—it is an abnormal reduction in the number of circulating red blood cells, the quantity of hemoglobin and the volume of packed red cells in a given unit of blood.
- Anaphylaxis**—it is an antigen-antibody reaction produced by the parenteral injection of an antigen causing hypersensitivity.
- Anastomosis**—it is a communication between two vessels.
- Anachoresis**—if the bacteria circulating in the bloodstream settle in areas of inflammation or of lowered resistance in the pulp and produce pulpitis, abscess or necrosis, the phenomenon is referred to as anachoresis.
- Anomaly**—deviation or irregularity as compared with the normal.
- Anorexia**—it is the lack of appetite.
- Anomalad**—it is a malformation together with its subsequently derived structural changes; the primary defect setting off a series of secondary or even tertiary events resulting in multiple anomalies
- Anosmia**—it is the absence of sense of smell.
- Antagonist**—it is any tissue that acts against or in opposition to another tissue.
- Anaplasia**—it is the reversion of the same type of cells from a more highly differentiated to a less highly differentiated type.
- Antibody**—it is any one of the class of substances produced in the body as a reaction to a specific antigen and with which, it reacts in some observable way to produce a specific effect such as inactivation, agglutination, and/or flocculation.
- Antibiotics**—these are substances produced by microorganisms which suppress the growth or kill other microorganisms at a very low concentration.
- Antidote**—it is an agent used to counteract or prevent the action of poisons.
- Antigen**—it is any substance that when introduced into the body, excites the formation of specific antibodies.
- Angioma**—a tumor made up of blood or lymph vessels.
- Ankyloglossia**—extensive adhesion of the tongue to the floor of the mouth or the lingual aspect of the anterior portion of the mandible caused by a short lingual frenum.
- Apertognathia (open bite)**—a condition in which the anterior or the posterior teeth of the mandible can not be brought into occlusion with antagonist teeth of maxilla.
- Aponeuroses**—these are collagenous sheets or ribbons that resemble flat, broad tendons. It may cover the surface of the muscle and assist in attaching superficial muscles or separate the structures.
- Aplasia**—absence of an organ or organ's part due to failure of development of the embryonic tissue of origin.
- Arteriosclerosis**—a condition characterized by loss of elasticity and thickening of artery walls.
- Atrophy**—it is a reduction in size of tissue or of an organ due to decrease in the size or number of its constituent cells.
- Atresia**—it is the congenital occlusion or absence of one or two major salivary gland ducts.

Atypical—irregular, not conformable to the type.

Attrition—it is the physiologic wearing away of tooth material as a result of tooth to tooth contact.

Auscultation—listening to the sound produced within the body with the help of a stethoscope.

Autogenous—it is produced within the body itself. It is self-generated.

Autograft—it is a graft taken from one of the patient's body and transplanted to another part in the same individual.

Autoantibody—an antibody that reacts against an antigenic constituent of the person's own tissues.

Autoimmune disease—a disease characterized by tissue injury caused by a humoral or cell-mediated immune response against constituents of the body's own tissues.

Autoimmunity—immune-mediated destruction of the body's own cells and tissues; immunity against self.

Autosomes—the non-sex chromosomes that are identical for men and women.

Autoinoculation—to inoculate with a pathogen such as a virus from one's own body.

Bacteremia—it refers to the circulation of bacteria in the blood.

Bacteria—these are microscopic unicellular vegetative organisms having a single chromosome, no nuclear envelope and a rigid cell wall. They may be seen as rods, cocci or filaments and divide by binary fission.

Bacteriostatic—it is any agent that inhibits the growth and multiplication of bacteria.

Baelz's disease—it is a disease characterized by the presence of painless papules on the labial mucous membrane (Cheilitis glandularis-superficial suppurative type).

Ballooning degeneration—it is characterized by the isolation of a cell from its neighbors, especially in the lower layers of the epidermis, the withdrawing of its prickles after intra-cytoplasmic edema and vacuolization and the mitotic division of its nucleus so as to form multinucleated giant cells.

Bay cyst—apical cyst which have a direct connection with apical foramen have been termed as 'bay cyst'.

Bednar' aphthae—two ulcers appearing symmetrically one on either side of the midline of the hard palate in infants, thought to be caused by the nipple or by thumb sucking or sucking hard object.

Benign—not malignant; favorable for recovery.

Bicameral abscess—it is an abscess which contains two chambers.

Biopsy—it is the gross and microscopic examination of tissue or cells removed from living patients for the purpose of diagnosis or prognosis of the disease or the confirmation of the normal condition.

Blanching—to take the color out of and make white.

Bleb—it is a bulla or other skin blister filled with blood or serous fluid.

Blind abscess—it is the one having no fistulous tracts.

Blister—it is a vesicle caused by localized accumulation of fluid beneath the skin.

Blood—it is the red fluid in the vessels of the circulating system which conveys oxygen and nutritive materials to the tissue and removes carbon dioxide and waste matter.

Blood pressure—it is the pressure exerted by the blood on the artery walls and is dependent on the force of heart action, the elasticity of the vessel walls, capillary resistance and the volume and viscosity of blood.

Blood transfusion—the intravenous administration of blood to help replenish excess blood loss due to hemorrhage or other wise, is known as blood transfusion.

Boil—it is a localized skin abscess usually at the site of a hair follicle.

Bosselated—having a knob like protrusion or bosses.

Bowen's disease—it is a localized intra-epidermoid carcinoma that may progress to invasive carcinoma over many years.

Bradycardia—it is an abnormal slowness of the heart and pulse rate.

Bradyglossia—it is an abnormal slowness of speech, due to difficulty in tongue movements.

Bradypnea—it is an abnormal slowness of respiration.

Bruise—it is a superficial injury, caused by a blow with no laceration but with discoloration of the skin and subcutaneous tissue produced by an accumulation of blood.

Bruxism—it can be defined as the involuntary, unconscious, and excessive grinding, tapping or clenching of teeth *or* it is defined as non-functional grinding or gnashing of the teeth, usually during sleep.

Buccal bifurcation cyst—a cyst of uncertain origin found primarily on the distal or facial aspect of a vital mandibular third molar, consisting of intensely inflamed connective tissue and epithelial lining.

Bullae—it is an elevated blister like lesion containing clear fluid and is bigger than 1cm in diameter.

Burrows—these are short, linear, straight or sinuous lines in the skin.

Burn—it is the injury resulting from the application of excessive heat, electric current, friction and caustics to skin or mucous membrane.

Carcinogenesis—carcinogenesis or oncogenesis or tumorigenesis means induction of a tumor agent which can induce tumor. The tumor agents are called as carcinogens.

Carabelli's cusp—it is an accessory lingual cusp located on mesiopalatine cusp of maxillary second primary molars and 1st, 2nd and 3rd permanent molars.

Capsule—compressed fibrous connective tissue around a benign neoplasm separating it from surrounding tissues.

Carcinoma—a malignant growth made up of epithelial cells that are capable of infiltration and metastasis.

Caries—demineralization of inorganic and dissolution of organic part of the tooth surface caused by bacteria.

Carcinoma in situ—it is a histopathological diagnosis defined as a proliferation of basal epithelial cells from the basement membrane to the surface, with almost all of the cells manifesting cytologic atypia. Immediate maturation into a superficial keratin layer is possible, but no invasion into the underlying connective tissues can be seen.

Calcareous—relating to or containing calcium or calcium salts; chalky.

Calcification—it is the deposition inorganic tissue of calcium salts causing hardening.

Calcinosis—it is a condition characterized by either localized or generalized deposition of calcium salts in nodules in the soft tissues.

Callus—the mesh of fibrous bony tissue surrounding and uniting the bone ends after fracture. It is later replaced by hard bone.

Camper's line—it is the line extending from the external auditory meatus to a point below the nasal point and is also called as facial line.

Cancellous—having a lattice like spongy structure; applied to bone tissue.

Canker—it is an ulceration especially of the mouth and lips and it is also called as aphthous stomatitis.

Capillary—these are one of the very fine thread like blood vessels connecting the veins and arteries.

Carbuncle—it is a staphylococcal infection of the sweat glands or hair follicles causing inflammation of the surrounding subcutaneous tissue and discharging pus through several openings, finally sloughing away.

Carcinosarcoma—it is a mixed tumor containing characteristics of both carcinoma and sarcoma.

Cariology—it is the scientific study of dental caries, its causes, prevention and treatment.

Carrier—the individual who continues to harbor infectious agent either following recovery from the illness it induced.

Cartilage—it is a form of elastic, nonvascular connective tissue attached to articular bone surfaces and also forming some parts of the skeleton.

Catabolism—it is the process of breakdown of complex compounds by the body.

Catarrh—it is the inflammation of the mucous membranes, especially those of nose and throat, with discharge of mucus.

Causalgia—it is a burning sensation arising after trauma to a sensory nerve.

Cellulitis—cellulitis may be defined as a non-suppurative inflammation of the subcutaneous tissue extending along the connective tissue planes and across the intercellular spaces.

Cell—it is one of the minute masses of protoplasm, containing a nucleus which forms the basis of all animal and plant structure.

Cementicle—it is a small calcareous body developing in the periodontal membrane.

Cell mediated immunity—it is the type of immunity in which the predominant role is played by T-lymphocytes.

Central—in oral pathology, it is the lesion occurring within bone.

Centromere—the constricted portion of the chromosome that divides the short arms from the long arms.

Chief complaint—it is the patient's response to the dentist's question.

Cheilitis—it is the inflammation of lip.

Chemoprophylaxis—it is the use of chemical drugs in the prevention of disease.

Chemotherapy—it is the treatment of a disease by chemicals which affect pathogenic organisms without harming the patient or it is the treatment of malignant neoplasia by chemical means.

Cheesy—lesion's texture is similar to curd of cheese.

Chemotaxis—taxis or movement in response to chemical stimulation.

Chromatin—a general term used to refer to the material (DNA) that forms the chromosomes.

Chronic—persisting over a long time; when applied to a disease, chronic means that there has been little change or extremely slow progression over a long period.

Chills—it is cold sensation with shivering, often characteristic of onset of fever.

Chloroma—it is a condition characterized by multiple myeloid tumors of greenish color, affecting particularly the face and skull, and associated with blood picture of leukemia.

Choriostoma—it refers to excessive amount of normal tissue that is present in abnormal location.

Chondromalacia—it is a condition characterized by abnormal softness of the cartilage.

Ciliated—having hair like processes or fringe of hair.

Circulation—it is the movement or flow in a circle, retracing its course repeatedly, applied especially to the flow of blood through the body.

Cleft lip—it is a birth defect that results in a unilateral or bilateral opening in the upper lip between the mouth and the nose.

Cleft palate—cleft palate is a birth defect characterized by an opening in the roof of the mouth caused by lack of tissue development.

Coagulation—when blood is shed, it loses its fluidity in few minutes and sets into a semisolid jelly. This is called as coagulation or clotting.

Cold abscess—it is a slow developing tuberculous abscess generally about a bone or joint and with little inflammation.

Collar stud abscess—it is a superficial abscess connected by a sinus tract to a larger deep abscess.

Complement system—this consists of a group of serum proteins which by series of reactions produce and release by products whose functions are to initiate an inflammatory reaction, to regulate and enhance phagocytic function and attack the bacterial cell membrane.

Congenital—present at or before birth but not necessarily inherited.

Coalesce—it is a term used to denote to fusion or union of separated parts.

Consanguinity—blood relationship. In genetics, the term is generally used to describe marriages among close relatives.

Corrugated—having a surface that appears wrinkled.

Cotton wool—confluent radiopacities.

Coarctation—it is narrowing or constriction, applied especially to blood vessels.

Col—it is a depression in an interdental papilla between the two peaks, one on each side of the contact area.

Coma—it is a state of complete unconsciousness from which a patient can not be aroused, even by determined external stimulation.

Commensal—it is an organism that lives on or within another organism, to its own advantage and without being detrimental to the host.

Commissure—it is the point of union between similar parts or bodies.

Concretion—it refers to any hardened or solidified mass in the tissue.

Counter irritation—it refers to the deliberate production of superficial irritation in order to mask or relieve an existing irritation or pain.

Concrescence—it is a form of fusion that occurs after the root and other major parts of the involved teeth are formed or when the roots of two or more teeth are united by cementum, below the cemento-enamel junction.

Cranio-malacia—it refers to a condition characterized by softness of bones of the skull, usually seen in infants.

Crater—it is a localized depression, usually circular, with raised edge or rim.

Crust—dry products of exudation from lesions occurring on skin and lips.

Crepitations—it refers to a crackling noise occurring in the joint when affected by certain disease.

Cryosurgery—it is the use of extreme cold for surgical destruction of tissue.

Cryotherapy—it is the treatment of disease with use of extreme cold.

Cryptogenic leukoplakia—in a small proportion of cases of leukoplakia, no underlying cause has been found. Such lesions are termed as idiopathic or cryptogenic leukoplakia.

Culture—it is the growth of microorganisms in an artificial medium.

Curettage—it refers to the removal of foreign matter from the walls of a bony cavity or from the root surface.

Cyst—cyst is a pathological cavity which may or may not be lined by epithelium and consists of fluid, semi-fluid or gaseous content (but not by pus) and surrounded by connective tissue capsule. True cyst is a pathologic cavity always lined by epithelium usually containing fluid or semi-solid material.

Cytology—is the scientific study of cell.

Cytopathic—pertaining to or characterized by pathologic changes in cells.

Cyanosis—it is the bluish discoloration of the skin and mucous membranes, often due to deficient oxygenation of the blood.

Dental kinesiology—it is the study of motion and function of jaws and oral musculature; the accompanying neurological, vascular and other supporting system network and the impact of those muscle functions and neurological dynamics have on dental and systemic health.

Developmental anomalies—malformation or defects resulting from disturbance of growth and development are known as developmental anomalies.

Dens in dente—it is also called as dens invaginatus. Infolding of the outer surface of the tooth into interior. It is a developmental variation which is thought to arise as a result of invagination in the surface of tooth crown before calcification occurs.

Dens evaginatus—dens evaginatus is a developmental condition that appears clinically as an accessory cusp or globules of enamel on occlusal surface between buccal and lingual cusp of premolars.

Debridement—it is the removal of dead tissue and foreign matter from a wound.

Degeneration—it refers to the gradual deterioration of tissue with loss of function and chemical changes within the tissue.

Dentistry—it is a branch of medicine concerned with oral and dental diseases and their prevention and treatment and with oral prosthesis.

Dentoalveolar abscess—an abscess that forms at the end of the tooth root.

Desmosomes—the term desmosomes refers to the structures forming the site of contact between adjacent cells, especially epithelial cells.

Desquamation—it refers to the peeling off of the outer layer of epithelium.

Dental fluorosis—a condition of enamel hypoplasia characterized by white chalky spots or brown staining and pitting of teeth due to an increased level of fluoride; affecting enamel matrix formation and calcification by impairment of ameloblastic function.

Dentigerous cyst—an odontogenic cyst that surrounds the crown of an impacted tooth; caused by fluid accumulation between the reduced enamel epithelium and enamel surface, resulting in a cyst.

Deoxyribonucleic acid (DNA)—a substance composed of a double chain of polynucleotide; both chains coiled around a central axis form a double helix. DNA is the basic genetic code or template for amino acid formation.

Dermoid cyst—a cyst of midline of the upper neck or the anterior floor of the mouth of young patients, derived from remnants of embryonic skin; consisting of a lumen lined by a keratinizing stratified squamous epithelium and containing one or more skin appendages such as hair, sweat or sebaceous glands.

Diffuse—used in the description of a lesion; when borders of the lesion are not well defined and it is not possible to detect the exact parameters of the lesion, then this term is used.

Diploid—having two sets of chromosomes; the normal constitution of somatic cells.

Diagnosis—it is the determination of the nature or cause of the disease.

Differential diagnosis—the list of similar clinical picture, according to probable identity of condition at hand, is the differential diagnosis.

Dimorphic anemia—it is a condition in iron deficiency and folic acid deficiency anemia can occur concomitantly.

Diploe—the spongy layer of bone position between the inner and outer layers of compact bone.

Diverticuli—they are small pouches or out pocket of the ductal system of one of the major salivary glands.

Disinfection—this is the process by which pathogenic microorganisms are removed from the surface, without removing bacterial spores.

Dilacerations—it refers to angulations or sharp bends or curves in the root and crown of the teeth.

Disease—it is the departure from the average anatomical structure or is an abnormal degree of failure of physiological function or some reduction in psychological efficiency, due to either adversity in the genetic endowment of the individual or misuse of his free will or to adverse factors in the environment in which he lives or some combination of these factors or it is defined as loss of ease.

Distomolar—found in the molar region frequently located distal to 3rd molar.

Discrete—separate. Composed of separate parts, not joined or blended.

Dislocation—it is the displacement of any part from its normal position, especially in the cases of bone and joints.

Direct fracture—it refers to the fracture that occurs at the site of blow.

DLE (discoid lupus erythematosus)—it is a circumscribed slightly elevated white patch that may be surrounded by a red telangiectic halo.

Dose—it is one measured portion of any medicine which is to be taken one at a time.

Dominant—in genetics, a trait or characteristic that is manifested when it is carried by only one of a pair of homologous chromosomes.

Dorsal—directed towards or situated on the back surface (opposite of ventral).

Dry abscess—it is an abscess that disperses without bursting or coming to a head.

Drainage—it is the gradual removal of fluid from a cavity or wound.

Dressing—it is a medicament used to promote wound healing or as a covering for a wound, used for protection or to assist healing.

Drug—it is any medicinal substance.

Drug addiction—it is state of periodic or chronic intoxication produced by the repeated consumption of drug and is harmful to individual and to society.

Drug habituation—it is the condition resulting from repeated consumption of drug, in which there is psychological and emotional dependency on the drug.

Drug dependence—a state psychic and sometimes also physical resulting from the interaction between a living organism and a drug, characterized by behavioral and other response that always includes a compulsion to the drug on a continues or period basis in order to experience its psychic effect and sometimes to avoid the discomfort of its absence.

Drug abuse/misuse—it is the improper or excessive use of therapeutic drugs even in the absence of addiction.

Dyskinesia—it is defined as an impairment of voluntary motions, causing movements that are incomplete or only partial.

Dysesthesia—it refers to the impairment of feeling or sensations; a condition in which a normal stimulus produces disagreeable sensations.

Dyskeratosis—this lesion shows abnormal orientation in development of epithelial cells.

Dysodontiasis—it refers to the painful, difficult or delayed eruption of the teeth.

Dysostosis—it refers to the congenital defective bone formation.

Dysphagia—an experience of having great difficulty in swallowing.

Dystrophic calcification—pathologic calcification that occurs in degenerating and dead tissue.

Dysplasia—it refers to the abnormal formation or development.

Dyspnea—it is a shortness of breath.

Ecchymosis—it refers to the diffuse extravasation of blood into the tissues. Larger purpuric lesions are called as ecchymoses.

Ectoderm—the outermost of the three primary germ layers of the embryo, from which are developed the epidermis, the external sense organs and the oral and anal mucous membranes.

Edema—it is accumulation of excess fluid in the intercellular tissue spaces or body cavities.

Electrocautery—it is cauterization by low voltage current producing burn like tissue repair, but with no control over the extent or quality of tissue destruction.

Electrodesiccation—it refers to the deeply penetrating tissue dehydration produced by the insertion of electrodes into the tissue.

Empirical therapy—with serious infections, it is often necessary to begin antibiotic therapy before culture result is available, this is called as empirical therapy which is directed towards organisms which are most likely to have caused that infection.

Embedded teeth—those teeth which are unerupted usually because of lack of eruptive force.

Embolism—it refers to the sudden blockage of blood vessels by a clot or other obstruction within the blood stream, causing failure of circulation.

Empyema—it is the accumulation of pus in a body cavity or a hollow organ.

Enamel pearls, nodules, or droplets—pearls or droplets described as small buttons or nodules of enamel usually about 1 mm or 2 mm in diameter that form on the root or at the bifurcation of multi-rooted teeth.

Embryonic—pertaining to the earliest stage of development of an organism.

Emigration—the passage of white blood cells through the endothelium and walls of small blood vessels.

Endotoxin—they are heat stable phospholipid-polysaccharide-protein complex contained as a structural part of the cell of many Gram-negative bacteria and released by disintegration of the cells.

Enanthema—it is an eruption occurring on a mucous surface or on any surface within the body as opposed to exanthema.

Endemic—prevalent in a particular region.

Endosteal—it is within the bone.

Endothelium—it refers to the membrane lining the heart and blood vessels.

Engorgement—it refers to the excess of blood in any part of the body or it is the localized congestion or distension.

Enostosis—it is a localized morbid bone growth arising within the bone cavity.

Enucleate—the word enucleate means to remove an organ or part, or a circumscribed, space filling lesion entirely, i.e. from its outer sheath or covering.

Endodermal—pertaining to the innermost of the three primitive germ layers of an embryo. Endodermal structures include the epithelium pharynx, respiratory tract (except the nose) and digestive tract.

Epidemic—affecting large number of people within an area or region.

Epidemiology—it is that branch of science concerned with the study of a disease or condition through its frequency and distribution.

Epithelium—it is a thin cellular layer covering or lining the organs and tissues of the body.

Eponym—the name of an organ, syndrome, disease, etc. that contains or is derived from a proper name.

Epulis—any tumor of the gums; more especially either a fibrous or a giant cell tumor.

Eruption—the act of appearing, or pushing through, as of teeth coming through the gums or a visible skin lesion occurring in disease.

Erythema—it is the redness in the skin either diffuse or patchy, caused by congestion of the subcutaneous capillaries.

Erythematous—it is characterized by a redness of the tissue due to engorgement of the capillaries in the region.

Erythroplastic—it is characterized by a reddish appearance. This term implies abnormal tissue proliferation in the reddish area.

Erythrocyte—one of the red cells found in blood which carries oxygen and is produced by the bone marrow.

Erythroplakia—the term is applied to any area of reddened velvety textured mucosa that can not be identified on the basis of clinical and histopathological examination as a cause of inflammation or any other disease process.

Erythrodontia—there is deposition of porphyrins in dentin and to a lesser extent in the enamel which imparts red or brown color to the deciduous and permanent teeth and known as erythrodontia.

Erosion—it is a shallow crater in the epithelial surface that appears on clinical examination as a very shallow erythematous area with only superficial changes or a moist red lesion often caused by rupture in vesicles and bullae as well as trauma.

Erosion (teeth)—it is loss of tooth substance due to chemical process that does not involve bacterial activity.

Erythroplasia—these are painless erythematous eruptions, papular or macular in nature, affecting the mucous membrane.

Eschar—it is a dry slough, the result of burning or due to contact with a corrosive agent.

Etiology—the study or theory of the factors that cause disease and their introduction to the host.

Eversion—a turning outward or a state being turned outwards.

Excrescence—it refers to an abnormal growth protruding from body or plant.

Exacerbation—it refers to an increase in the severity of a disease or any symptoms.

Examination—it refers to investigations carried out for diagnostic purpose.

Exanthema—it is an eruptive fever.

Excoriation—it is the superficial loss of surface skin or a graze.

Excursion—it refers to any movement of a movable part from a resting position during the performance of some functions.

Exfoliation—it is the peeling off in layers or in scales.

Exophthalmos—it refers to the abnormal protrusion of the eyeball.

Exophytic—it refers to a word relating to something growing outwards, used for tumor projecting above the normal surface contours or it refers to any pathological growth that project above the normal contours of the oral surface.

Expansile—capable of being extended or expanded.

Expressivity—in genetics, the degree of clinical manifestation of a trait or characteristic.

Exostosis—it is a bony swelling developing on the bone surface or on a tooth root.

Exotoxin—it refers to a toxic secretion of bacterial cells which cause damage in sites distant from the focus of infections or they are heat labile proteins which are secreted by certain bacteria and diffuse readily into surrounding tissue.

Extravasation—it is the escape of fluid from vessels into the surrounding tissue.

Extrinsic—having its origin outside and separated from a body, organ or part.

Exudate—the matter that passes out into adjacent tissues through vessel walls in inflammation.

Facies—the appearance of the face.

Factitial injuries—these are accidentally self-induced injuries on the basis of habits with frequent psychological backgrounds.

Favorable fracture—if the fracture line runs in such a manner that the associated muscle tends to hold the fragments together, the fracture is described as favorable.

Facet—it is a small abraded area on a bone or on tooth surface.

Familial—relating to a family, or affecting several of its members.

Fascia—it is the layer of areolar tissue beneath the skin or the layer of areolar tissue investing the muscles, nerves and other organs.

Fenestrate—to pierce with one or more holes, sometimes used on the walls of bony defect in an attempt to stimulate repair.

Fenestration—it refers to a surgical procedure by which one or more holes are pierced in hard tissue.

Fever—it refers to an abnormal increase in body temperature.

Final diagnosis—it is statement with which precise diagnosis has been made on the basis of all required observation, identification of definitive symptoms and the pathological report and patient response to therapy.

Fibro-cemento-osseous lesions—it is a skeletal disorder in which bone is replaced by fibrous tissue which in turn is replaced by mineralized tissue.

Fissure—it is a linear often crusted, tender, painful defect in continuity of the skin, occurring usually at the mucocutaneous junctions and at sites where there is considerable elasticity of the skin.

Fistula—it is communicating tract between two epithelial surfaces which is lined by granulation tissue which is subsequently epithelialized.

Fibrosis—there is an abnormal formation of fibrous tissue.

Fluctuant—a wave-like motion felt on palpating a cavity with non-rigid walls, especially one containing fluid.

Fluoride mottling—a condition of enamel hypoplasia characterized by white chalky spots or brown staining and pitting of teeth due to an increased level of fluoride affecting enamel matrix formation and calcification by impairment of ameloblastic function.

Focus of infection—it refers to a circumscribed area of tissue, which is infected with exogenous pathogenic microorganisms and which is usually located near a mucous or cutaneous surface.

Focal infection—it refers to metastasis from the focus of infection of organisms or their products that are capable of injuring tissue.

Foramen—a small hole in a bone through which passes either blood vessels or nerves or both.

Focal osteitis—a condition sometimes occurring after tooth extraction, particularly after traumatic extraction, resulting in a dry appearance of the exposed bone in the socket, due to disintegration or loss of the blood clot.

Foreign body granuloma—a reaction to foreign materials that are too large to be ingested by either microphages (PMNs) or macrophages.

Frenal tag—a redundant piece of mucosal tissue that projects from the maxillary labial frenum.

Fusion—it is also called as synodontia. It represents the embryonic union of normally separated tooth germs.

Fulguration—it refers to the superficial tissue dehydration produced by a surgical electrode held slightly away from the tissue, causing sparking.

Galvanism—the production of an electric current caused when two dissimilar metals used as restorations in the mouth come into contact, this can cause discomfort and even pain.

Gangrene—it is the necrosis of tissue due to failure of the arterial blood supply caused by injury or disease.

Gelation—the process of change of a colloid from a sol to a gel.

Gerodontia—it is that branch of dentistry which deals with the care of old people.

Gemination—it refers to the process whereby single tooth germ invaginates resulting in incomplete formation of two teeth that may appear as a bifid crown on a single root.

Genetic heterogeneity—having more than one inheritance pattern.

Ghost teeth—a developmental disturbance of several adjacent teeth in which the enamel and dentin are thin and irregular and fail to adequately mineralize; surrounding soft tissue is hyperplastic and contains focal accumulations of spherical calcifications and odontogenic rests.

Gingivosis—it refers to the any degenerative condition affecting the gingiva.

Gland—an organ that produces secretions.

Glossodynia—it refers to the burning or painful condition of the tongue.

Gomphosis—it is the firm attachment of two bones without a movable joint.

Gorham's disease—in this condition a large portion of bone disappears with any apparent cause.

Granuloma—a tumor composed of granulation tissue.

Granulomatosis—it refers to the development of multiple granuloma.

Granulation tissue—it is the reparative tissue that is formed on the surface of wound having pink, soft, granular appearance showing histologically new small blood vessel and fibroblast.

Green stick bone fracture—it is a fracture in which one side of bone is broken and the other side is bent but intact.

Ground glass—fine radiopaque spots in radiolucent background.

Gustatory—the sense of taste or the act of tasting.

Hamartomas—it is a tumor like malformation of oral tissues, developmental in origin with tissue being native to the site.

Habit—it is a tendency toward an act or an act that has become a repeated performance, relatively fixed, constant, easy to perform and almost automatic.

Hemoglobinopathies—these are a group of hereditary disorders characterized by the presence of structurally abnormal hemoglobin.

Hereditary disease—they are apparent at birth but some may not become evident for years.

Hemoptysis—the presence of blood in the sputum caused by bleeding in the upper respiratory tract or the lungs.

Hemorrhage—it refers to the internal or external loss of blood due to injury or other damage to blood vessels.

Hemidesmosome—it refers to a structure found on the basal surface of an epithelial cell, the attachment site between the cell and the underlying membrane.

Heredity—it refers to the transmission of a characteristic from parent to child or to later generation.

Heterotrophic—it is a term used relating to organisms which require a complex source of carbon for nourishment and growth.

Hematoma—it is large clot resulting from blood released into the tissue from a ruptured or injured blood vessel.

Healing—it is repair and replacement of dead or damaged cells by healthy cells.

Histology—it refers to the study of the anatomy and physiology of tissue and cells using microscopic technique.

Holistic—it refers to an approach to treatment that takes into consideration the whole person, not just the disease or condition.

Homologous—having the same or corresponding structure or position but not necessarily similar in function.

Horner's teeth—incisor teeth with horizontal grooves caused by enamel deficiency.

Hypodontia—it refers to the absence of one or more teeth.

Hypertrophy—it refers to the enlargement caused by an increase in size of cells.

Hydrocyst—it refers to a cyst whose contents are watery in nature.

Hyperplasia—it refers to the enlargement caused by increase in number of cells.

Hypoplasia—it is the failure of full development of an organ or tissue.

Hydrostomia—it refers to a condition characterized by constant dribbling from the mouth.

Hygroma—it refers to a swelling caused by fluid surrounding an inflamed bursa, or distending a sac or cyst.

Hypertension—exceptionally high tension especially abnormally high blood pressure.

Hypnosis—it refers to a sleep or a trance state, especially one induced artificially by verbal suggestions or concentration upon some object.

Hypsodont—having teeth with long crowns and short roots seen in herbivorous animals.

Hydropic degeneration—it refers to replacement of the nuclei of stratum basal by clear space due to edema and degeneration of cells.

Iatrogenic diseases—these are the diseases produced by the action of a doctor or due to medical treatment.

Idiopathic—it is any spontaneous or primary disease with no apparent external cause

Idiosyncrasy—it refers to a reaction to a particular drug in therapeutic doses in a manner not necessarily related to its pharmacological properties.

Impacted teeth—they are those prevented from erupting by some physical barriers in the eruption path.

Immunity—it is the resistance exhibited by the host towards injury caused by microorganisms and their products.

Impermeable—not permitting passage especially of fluids.

Implant—the word implant means to insert into the body or to graft as in plastic surgery.

Infection—it is a clinicopathological entity-involving invasion of the body by pathologic microorganisms and the reaction of tissues to microorganism and their toxins.

Inspection—it refers to an examination of the affected part of the body.

Internal derangement—it can be defined as mal-relationship of the meniscus to the condylar head and articular eminence where an alteration of its attachment allows the meniscus to assume an abnormal position.

Inflammatory collateral cyst—it is a cyst which arises in the periodontium of an erupted tooth as a result of inflammatory process in the periodontal pocket.

Involucrum—small section of necrotic bone may be completely lysed, while a large one may get localized, and get separated and form shell of new bone called involucrum by a bed of granulation tissue or a sheath particularly new bone sheath that forms about sequestration.

Indirect fracture—fracture site distant from where the actual blow takes place, usually seen on contralateral side.

In vitro—within glass referring to observations made in a test tube or culture dish as opposed to *in vivo*.

In vivo—within a living organism.

Indentation—it refers to the condition of being serrated or notched.

Induced—brought on by an outside agent or is artificially produced.

Induration—it refers to the state of being hard or the process of becoming hard.

Inflammation—it is the reaction of living tissue to injury.

Infarction—it is a localized area of ischemic necrosis in an organ or tissue resulting from sudden reduction of either its arterial supply or venous drainage.

Inflation—it refers to the distension with gas especially air.

Inostosis—it refers to the process by which bony tissue is reformed to replace tissue that has been destroyed.

Insidious—unperceived coming on gradually and stealthily.

Intermittent—occurring at intervals with periods of cessation.

Intubation—it refers to the introduction of a tube through the mouth or the nose to allow air, gas or vapor to pass into the lungs.

Iontophoresis—it refers to the therapeutic treatment by electrical introduction of ions into the body tissue.

Ischemia—it refers to the deficiency in the blood supply to a part or an organ which may be due to constriction, contraction or blocking of the arteries.

Isograft—it refers to a graft derived from one member of a pair of monozygotic twins and transplanted to the other.

Jaw winking—it refers to a movement of the lower jaw causing an involuntary movement of the eyelids.

Joint—the place of connection between two bones, allowing of more or less movement on articulation.

Keloid—it refers to a fibrous hyperplastic scar growth on the skin.

Kernicterus—staining of brain tissue caused by accumulation of unconjugated bilirubin in the brain.

Knitting—it refers to the process of repair of a bone fracture.

Lain's disease—burning of the tongue and the soft tissue of the mouth due to electrogalvanism caused by the use of dissimilar metals in dental restoration.

Lancinating—it is the term used to describe shooting, tearing or sharply cutting type of pain.

Leukoplakia—A white patch or plaque that can not be scraped off and can not be characterized clinically or pathologically as any other disease, which is more than 5 mm.

Lesion—a wound or injury or a patch of disease on the skin. A morbid change in tissue function.

Lichen planus—relatively common dermatitis occurs on skin and oral mucous membrane and refers to a lace-like pattern produced by symbiotic algal and fungal colonies on the surface of rocks in nature.

Lipomatosis—it refers to excessive localized accumulation of fats in the tissues.

Ludwig's angina—this condition may be defined as an overwhelming rapidly spreading septic cellulitis involving submandibular, submental and sublingual space bilaterally.

Lymph—it refers to the clear fluid found in the lymphatics vessels.

Lymphadenitis—it refers to the inflammation of the lymph nodes.

Macule—well-circumscribed flat lesion that is noticeable due to the change from the normal skin color to red may be due to inflammation or pigmented due to presence of melanin hemosiderin or other drugs.

Maceration—it refers to the softening of a substance by soaking in a liquid.

Malocclusion—it refers to any deviation from the normal occlusion of the teeth resulting in impaired functions.

Marrow—it refers to the soft tissue canal and interstices of bones.

Marsupialization—it refers to an operation for the evacuation of a cyst and the suturing of its walls to the edges of the wound.

Metastasis—it is defined as spread of tumor by invasion in such a way that discontinuous secondary tumor mass/masses are formed at the site of lodgment.

Metaplasia—it is a reversible change in which one adult cell type is replaced by another adult cell type.

Mesiodens—it refers to supernumerary tooth located at or near the midline in the incisal region of maxilla between the central incisors.

Medicine—it refers to the study and treatment of diseases especially treatment without recourse to surgery or any drug used for the treatment of the disease.

Metabolism—it refers to the physical and chemical changes in the tissue by which a living body is maintained and energy generated.

Mitosis—it is the indirect division of cells, a typical method of cell reproduction.

Mucocele—it is a term used to describe swelling caused by pooling of saliva at the site of injured minor salivary gland.

Muscle—it is a contractile organ by means of which movement is produced in an animal organism.

Muscle spasm—it refers to a sudden involuntary contraction of the muscle or group of muscles attended by pain and interference with function.

Mucus plug—these are incompletely mineralized sialoliths.

Natal teeth—these are teeth which are observed in the oral cavities at birth.

Narcosis—a state of profound unconsciousness or stupor produced by drugs.

Nausea—a feeling of sickness or a tendency to vomit.

Necrosis—it is the sum of the morphologic changes that follow cell death in a living tissue or organs.

Neonatal teeth—these are teeth which erupt during the first 30 days of life.

Neoplasia—it is an abnormal mass of tissue, the growth of which exceeds and is un-coordinate with that of normal tissue and persists in the same excessive manner after cessation of stimuli which evoke the changes.

Neurotropic—attracted to or having an affinity for nervous tissue.

Nevus—it is circumscribed new growth of skin or oral mucosa of congenital origin, presenting as small, elevated, or flat pigmented lesion.

Nodules—this lesion is present deep in the dermis and epidermis and can be moved easily over them.

Nociceptive—relating to any pain producing stimulus, or to pain receptor nerves.

Nosology—it refers to the science of classification of disease.

Numbness—partial or total loss of sensation which may be deliberately induced as in cases of local anesthesia or it may be pathological.

Nutrition—it refers to the process by which food is assimilated.

Ointment—it refers to a fatty semisolid substance used as a base for local medicaments for external application.

Oligodontia—it is agenesis of a few numbers of teeth.

Oncology—it refers to the study of neoplasm.

Operation—anything performed, especially any procedure by a surgeon, either with instruments or by hand.

Oroantral opening—the accidental opening in the floor of maxillary sinus during dental extraction is called as oroantral opening.

Oral submucosa fibrosis—an insidious chronic disease affecting any part of the oral cavity and sometimes the pharynx, preceded by and/or associated with vesicle formation, it is always associated with juxtaepithelial inflammatory reaction followed by fibro-elastic change of the lamina propria, with epithelial atrophy leading to stiffness of the oral mucosa and causing trismus and inability to eat.

Oral medicine—it is that area of dental practice which deals with diagnosis and treatment of oral disease by non-surgical means, which may be localized in the oral cavity or which may be oral manifestation of systemic disease and those phases of dental practice concerned with diagnosis and treatment of medically compromised patients.

Organ—it refers to any separate part of the body having a specific function.

Organism—it refers to any individual plant or animal or an organized body of living cells.

Osteomyelitis—it is an inflammation of bone marrow that produces clinically apparent pus and secondarily affects the calcified component or it is an infection of bone that involves all three components: periosteum, cortex, and marrow or it may be defined as an inflammatory condition of the bone that begins as an infection of the medullary cavity and the Haversian system which extends to involve the periosteum of the affected area.

Papules—these are solid lesions raised above the skin surface that are smaller than 1 cm in diameter.

Pathogenicity—it is the ability of microbial species to produce disease.

Paramolar—it is a supernumerary molar usually small and rudimentary which is situated buccally or lingually to one of the maxillary molars or interproximally between 1st, 2nd and 3rd maxillary molars.

Palpation—it refers to feeling of the affected part by hand.

Pain—it refers to the distressing or unpleasant sensation transmitted by a sensory nerve usually indicative of injury or of disease.

Palliation—it refers to the act of alleviating or affording relief without curing.

Paresthesia—the term refers to perverted sensation like burning, prickling or crawling sensation of the skin.

Parageusia—it refers to an unpleasant taste in the mouth.

Parakeratosis—it refers to any abnormality of the stratum corneum of the epidermis, which may be associated with inflammation of the prickle cell layers causing defective formation of keratin and characterized by the persistence of nuclei.

Paralysis—it is the loss or impairment of muscle function or of sensation due to nerve injury or destruction of neurons.

Pararhizoclasia—it is the inflammatory ulcerative destruction of the deep layers of tissue and the alveolar process about the root of a tooth.

Parenteral—descriptive of methods of drug administration other than by the alimentary canal.

Parodontal—near or next to a tooth sometimes used as synonymous with periodontal.

Parrot tongue—a horny, dry tongue which can not be protruded, seen in typhus and low fever is called as parrot tongue.

Pathogen—any agent that produces or is able to produce disease.

Parulis—it is a mass of granulation tissue which covers the opening of a sinus.

Pathogenesis—the development of disease from its inception to the appearance of characteristic symptoms or lesions.

Pathognomonic—characteristic of one specific disease or pathological condition as distinct from any others.

Pathology—that branch of medicine which is concerned with the structural and functional changes caused by disease.

Pedunculated—in this base of tumor is narrower than the widest part of lesion.

Peridens—supernumerary teeth that are erupted ectopically either buccally or lingually to the normal arch referred to as peridens.

Petechiae—purpuric lesions 1 to 2 mm in diameter.

Permeation—the spreading or extension through tissues or organs, used especially of malignant tumors extending by continuous growth through the lymphatics.

Pericemental abscess—a parodontal abscess not arising from a diseased pulp or an extension of the periodontal pocket.

Percussion—listening to the tapping note with a finger placed on the affected part or in cases of teeth with the help of handle of the probe.

Periodontitis—it is name given to periodontal disease when the superficial inflammation in the gingival tissue extends into the underlying alveolar bone and there is loss of attachment.

Periodontal abscess—an abscess that forms deep in the gums along the tooth root following advanced periodontal disease.

Periodontosis—chronic non-inflammatory destruction of periodontal ligament and the associated alveolar bone.

Phoenix abscess—it is an acute exacerbation of a chronic or suppurative apical periodontitis.

Phlegmon—acute inflammation of the subcutaneous connective tissue.

Pit—it is defined as hollow fovea or indent blind tracts lined with epithelium.

Pilation—it is a hair like fracture found in cranial bones.

Plasmapheresis—it is a method of increasing the number of blood cells in the blood count. From the blood plasma is skimmed out simply on standing and remaining concentrate is reinfused into the patient.

Plaque—it is a solid raised lesion that is over 1cm in diameter.

Pleomorphic—the word pleomorphic means occurring in several distinct shapes.

Pleurodont—having teeth attached to the side of a bony socket or to the side of the jaw.

Plexus—a plexus of nerves or a network of blood or lymphatic vessels.

Pocket—it is an abnormal space developing between the tooth root and the gums.

Poison—any substance that when absorbed into the system of a living body is liable to cause injury and to endanger life.

Poikiloderma—it refers to a combination of atrophy, telangiectasia and pigmentary changes.

Polylophodont—these are teeth with multi-ridged crowns.

Pre-cancerous lesion—morphologically altered tissue in which cancer is more likely to occur than its normal counterpart.

Pre-cancerous condition—it is a generalized state associated with a significantly increased risk of cancer.

Premedication—the administration of drugs or sedatives before treatment, to help in patient management especially with nervous patient.

Prescribe—to write instruction for the preparation, composition and administration of a medicine.

Prevalence—the number of cases of a disease at any given time in any given place.

Priestley's mass—a green or brown stain on the anterior teeth of the young or where reduced enamel epithelium remains over the enamel.

Procheilia—it is the condition in which one lip protrudes forwards of its normal position.

Prognosis—it is the prediction of the course, duration, and termination of the disease and the likelihood of its response to therapy.

Prosthesis—the word prosthesis is used for a manufactured appliance used to take the place of a natural part or to correct a congenital abnormality or it may be defined as an appliance which replaces lost or congenitally missing tissue.

Proteolysis—the process of digestion of proteins and its conversion by enzymes into peptones, proteoses, etc.

Protuberance—the word protuberances refers to a swelling, eminence or knob of the tissue.

Pseudomembrane—it refers to a false membrane, a skin like layer formed by fibrinous exudates containing leukocytes and bacteria.

Pseudoepitheliomatous hyperplasia—in this condition the rete pegs extend far downward, usually accompanied by acanthosis. The cells are normal in size, shape and chromaticity.

Psychosomatic—relating to the mind and the body; particularly relating to the interdependence of mental processes and bodily function.

Pustule—it refers to a raised lesion containing purulent material.

Purpura—it refers to reddish to purple flat lesion caused by blood extravasated from a vessel leaking into subcutaneous tissue.

Pulsation—it is the rhythmic throb or beating as that of the heart.

Pulse—the expansion and contraction of an artery due to increased tension of its walls following contraction of the heart and subsequent relaxation.

Pus—it is a liquid usually yellowish in color formed in certain infection and composed of tissue fluid containing bacteria and leukocytes.

Putrefaction—the decomposition of organic matter through the action of microorganisms, resulting in the production of various solid and liquid compounds and gases giving off a foul odor.

Pyemia—generalized septicemia caused by pyogenic microorganism in the blood stream and marked by the formation of multiple abscesses.

Ranula—the term ranula is used for a mucocele occurring in the floor of mouth in association with ducts of the submandibular or sublingual glands.

Radiology—it is that branch of health sciences dealing with radioactive substances and radiant energy and with the diagnosis and treatment of disease by means of both ionizing (X-rays) and non-ionizing (ultrasound) radiations.

Radiolucent—offering little resistance to X-rays in radiography; almost transparent.

Rash—it refers to a temporary cutaneous eruption.

Recrudescence—the return of symptoms or the recurrence of the disease after a temporary remission.

Recurrence—the return of symptoms or of a disease after a period of remission.

Regurgitation—the return of undigested or partially digested food from the stomach or esophagus to the mouth or of fluid or semifluid to the nose.

Reticular—relating to net or net like structure.

Regeneration—it is replacement of injured tissue by parenchymal cells of the same types.

Retrogenia—it refers to a condition in which chin is set back in relation to the rest of the facial skeleton.

Rh hump—in the deciduous 1st molar crown a characteristic ring like defect may be seen which is called as Rh hump.

Rhinorrhea—it refers to any discharge of fluid from the nose.

Rhizotomy—a surgical division of either a tooth root or a nerve root.

Root dehiscence—it is a pathological condition in which the vestibular surface of the tooth root is exposed to the oral cavity over some or all of the apical two-third of its length.

Rudiment—it refers to an organ or part either imperfectly developed or at an early stage of development.

Rubber jaw—in this condition it is possible to mold the shape of the jaw with the fingers, but teeth will resume its position when the pressure is released.

Satellite abscess—it is a secondary abscess arising from and situated near a primary abscess.

Saburra—it refers to a foul condition of the mouth and teeth or of the stomach due to food debris.

Saucerization—it is the wide and shallow depression occurring about a wound or bone cavity as in osteomyelitis.

Sclerosis—it refers to hardening of vessels or part applied particularly to arteries and to proliferation of connective tissue in the nervous system as a result of degeneration.

Scale—loosened imperfectly cornified parakeratotic superficial layer of skin that is shed as fine, brawny, dirty white, yellowish keratinous dust or large pearly white flakes.

Sequestra—small pieces of necrotic bone which are avascular and which harbor microorganisms are known as sequestra.

Serum—if blood is allowed to clot an amber colored liquid which remains after separation of the clot is known as serum.

Septicemia—the word septicemia implies a overwhelming bacterial proliferation and release of toxins in the blood.

Sessile—it described tumor or growth whose base is widest part of the lesion.

Shock—it is state of inadequate perfusion of all cells and tissues, which at first leads to reversible hypoxic injury, but if sufficiently protracted or grave, to irreversible cell and organ injury and sometimes to the death of the patient.

Sickle cell anemia—in homozygous individuals the whole of HbA (hemoglobin A) is replaced by HbS (hemoglobin S, i.e. an abnormal hemoglobin) and this is known as sickle cell disease.

Sickle cell trait—in heterozygous individuals only 50% of HbA is replaced by HbS and this is known as sickle cell trait.

Sinus—it is a blind tract leading from the surface down to the tissue which is lined by granulation tissue or which may be epithelized.

Sialorrhea (ptyalism)—an increased salivary secretion is termed as sialorrhea or ptyalism.

Sialolithiasis—it is the formation of calcific concretions within parenchyma or ductal system of major or minor salivary glands.

Sinusitis—inflammation of mucosa of paranasal sinuses is referred to as sinusitis. When maxillary sinus is involved it is called as maxillary sinusitis.

Sialoschesis—it is the suppression of the secretion of the salivary glands.

Sign—it defined as any change in the body or its function which is perceptible to a trained observer and may indicate a specific disease.

SLE (systemic lupus erythematosus)—it is characterized by the presence of abnormal serum antibodies and immune complexes.

Slough—it refers to the necrotizing tissue that scales or peels off in ulcerative conditions.

Spongiosis—this term is used to signify intercellular edema of the epithelium, in which intercellular bridges of the stratum spinosum become more prominent.

Stagnation—it refers to the cessation of flow of any circulating fluid in the body.

Sterilization—it is the process of destruction of the microbial life from an article or surface inclusive of bacterial spores.

Sterile abscess—it refers to an abscess containing no microorganisms.

Stenosis—it is the constriction or narrowing of an aperture canal or duct.

Stimulus—it refers to any agent or impulse that excites or promotes a functional reaction.

Stippled—having a mottled or spotted appearance with light and dark patches.

Stomatology—the medical speciality concerned with the mouth and its diseases sometimes used synonymously with dentistry.

Striation—it is a stripe or streak or a series of stripes or streaks.

Stricture—it is an abnormal contraction of any aperture or vessels.

Stridor—it is a harsh whistling sound produced by the respiratory system.

Superficially invasive (micro-invasive) squamous cell carcinoma—a histopathological diagnosis of a routine squamous cell carcinoma, usually well differentiated, which has invaded only slightly into the underlying connective tissues.

Subluxation (hyper-mobility)—it is the unilateral or bilateral positioning of the condyle anterior to the articular eminence, with repositioning to normal to accomplish normal physiologic activity.

Subscription—it is a part of a prescription containing direction for the preparation and compounding of the ingredients of a medicine.

Suzanne's gland—an oral mucous gland found in the alveolo-lingual sulcus near the midline.

Symbiosis—it is the intimate association of two organism of different species.

Symptoms—any indication of the presence or course of a disease either by functional or other changes occurring in the patient.

Syncope—it is a transient loss of consciousness caused by cerebral hypoxia or changes in cerebral blood flow.

Syndesmosis—it is the joining of two bone surfaces by the interposition of connective tissue which forms an interosseous membrane.

Syndrome—a complex of symptoms, occurring together, which characterize one disease or lesion.

Talon's cusp—it projects lingually from the cingulum area of maxillary and mandibular teeth or it is anomalous hyperplasia of cingulum on the lingual of maxillary and mandibular incisor resulting in the formation of a supernumerary cusp.

Taurodontism—body of tooth is enlarge at the expense of root. It is characterized by clinical and anatomical crown of normal shape and size, an elongated body and short root with a longitudinally enlarged pulp chamber.

Tablet—it is a small solid disc containing one dose of a drug.

Tapir mouth—it is a condition characterized by loose thickened lips and caused by atrophy of the orbicularis oris muscle.

Taste—the perception of flavor, a sensation produced by stimulation of the gustatory nerve endings in the tongue with a soluble substance.

Telangiectasia—it is the dilatation of the capillaries and small arteries forming types of angiomas.

Teratoma—it is true neoplasm made up of a number of different types of tissue which are not native to the area in which the tumor occurs.

Thalassemia—it is an inherited impairment of hemoglobin synthesis in which there is partial or complete failure to synthesize a specific type of globin chain.

Therapy—it refers to the treatment of disease.

Thermocautery—it is the use of heat points for cauterization.

Tic—a spasmodic twitching particularly of the facial muscles; a habit spasm.

Tinnitus—the term refers to a ringing noise in the ears.

Toxin—it is a poisonous substance produced by animal or vegetable cells more particularly by bacteria.

Trabeculae—it refers to a septum extending from the outer capsule or envelop into an organ.

Trephine—these are substances prepared by leukocytes from the plasma protein which is necessary for nourishment of tissue cell.

Transplantation—it is the transfer of tissue either from another donor or from one site to another.

Transposition—it is the interchange in position of two adjacent teeth.

Treatment—it is the means used to combat or cure a disease.

Trigonodont—a tooth having three cusps in the form of a triangle.

Trismus—it is the inability to open the mouth because of tonic spasm of the jaw muscles.

Tropics—it is that portion of the surface of the globe where the sun passes directly overhead.

Tumor—it is an autonomous new growth of tissue or it is an abnormal mass of tissue the growth of which exceeds and is uncoordinated with that of normal tissue and persists in the same excessive manner even after the cessation of stimuli which evoked changes.

Tubercle—it is a rounded eminence on bone.

Tumefaction—it is the state of being or becoming swollen.

Twining—it indicates the cleavage of tooth germ into two complete resulting in formation of supernumerary teeth that is mirror image or near image of tooth from which it has developed.

Tyndallization—a method of sterilizing culture media by exposure to steam at 100°C on three successive days for—about 30 minutes each day.

Ulcer—deep crater that extends through the entire thickness of the surface epithelium and involve the underlying connective tissue or defect in epithelium, it is a well circumscribed depressed lesion over which epidermal layer is lost.

Unfavorable fracture—if the associated muscle tends to pull the fragment of the fracture, it is described as unfavorable.

Uvuloptosis—it is a relaxed dropped position of palatine uvula.

Vaccine—it is any material used for preventive inoculation against a specific disease.

Vallate—having a surrounding wall or rim.

Varicosity—it refers to a distended vein, superficial, bluish and painless.

Vasodilator—the term refers to a nerve or some external agent which cause vascular dilatation.

Vesicle—these are elevated blisters containing clear fluid that are under 1 cm in diameter.

Vertigo—it is a sensation of loss of equilibrium in which sufferers feel either that the world is revolving round them or that they are revolving in space.

Verrucous—in this tumor exhibits numerous surface projection.

Virulence—it is a term applied to the properties in a particular strain of microorganism.

Vicarious—relating to a normal process occurring in an abnormal position or under abnormal conditions.

Virus—a complex organic particle of submicroscopic dimensions capable of growth and reproduction only within the cells of the host organism it infects.

Wasting disease of teeth—it is defined as any gradual loss of tooth substance characterized by the formation of smooth polished surfaces without ragged to the possible mechanism of this loss.

Wandering teeth—it is movement of unerupted teeth for no apparent reasons (distal drift).

Wandering abscess—an abscess that tracks through the tissue and finally comes to a point some distance from the original site.

Weal—it is a reddish, raised and circumscribed lesion on the skin, generally caused by a blow or a bite.

Working diagnosis—following reappraisal of diagnostic data at hand including those of follow-up examination which may be seen necessary and which may provide new relevant finding and indicating result from any additional diagnostic procedure.

Wound—it is any injury to the tissues or organs caused by cut, stab or tear, usually going deeper than the outer skin or integument.

Wolf's law—this law states that, the bone structure depends on the strain and stresses to which bone is subjected.

Xerostomia—it is a subjective clinical condition of less than normal amount of saliva.

Xenograft—it is a type of graft derived from a donor of different species.

4

Multiple Choice Questions

1. Hereditary hemorrhagic telangiectasia is seen commonly on:
A. Lips B. Buccal mucosa
C. Tongue D. Palate
2. Raised and pearly white beaded edge is a feature of:
A. Gummatous ulcer B. Rodent ulcer
C. Healing ulcer D. Tuberculous ulcer
3. "Starry sky" appearance is seen in:
A. Pagets disease
B. Cherubism
C. Burkitt's lymphoma
D. Osteomyelitis
4. Delayed type of hypersensitivity reaction to topical antigen is termed as:
A. Stomatitis B. Stomatitis venetana
C. Contact allergy D. Both A and C
5. Kaposi sarcoma is a tumor of:
A. Blood vessels B. Striated muscle
C. Smooth muscle D. None of the above
6. Bednar ulcer is a type of:
A. Traumatic ulcer B. Herpes ulcer
C. Aphthous ulcer D. Allergic ulcer
7. Verocay bodies is associated with:
A. Granular cell myoblastoma
B. Neurilemmoma
C. Neurofibroma
D. Neuralgia
8. Patch test is positive in:
A. Contact allergy
B. Erythema multiforme
C. Aphthous stomatitis
D. Behcet's syndrome
9. All of the above are precancerous condition except:
A. Systemic lupus erythematosus
B. Plummer-Vinson syndrome
C. Lichen planus
D. Syphilis
10. Sutton's disease the ulcer is:
A. Less than 1 cm in diameter and heal without scar
B. Occurs in crops
C. Associated with Beçhet's syndrome
D. More than 1 cm in diameter and heal with scarring
11. Rhabdosarcoma spread by:
A. Local infiltration
B. Lymphatics
C. Blood
D. Direct invasion
12. Bowen disease is:
A. Benign neoplasm of gastrointestinal tract
B. Ulcerative lesion of the skin
C. Vesiculobullous lesion
D. Intra epithelial carcinoma
13. 70-year-old patient comes to the clinic with a tumor of buccal mucosa. The size of the tumor is 3 cm in size with no regional lymph node involvement and no distant metastasis. The TNM stage of the tumor is:
A. T1 N0 M0
B. T2 N0 M0
C. T1 N1 M0
D. T1 N2 M0
14. Radiographic finding of the Pindborg's tumor is:
A. Sunburst appearance
B. Onion peel appearance
C. Driven snow appearance
D. Cherry blossom appearance
15. Ghost cell are seen in:
A. CEOC
B. Ghost teeth
C. AOT
D. OKC
16. The lesion commonly seen in anterior maxilla:
A. Composite compound odontoma
B. Adenomatoid odontogenic cyst
C. Squamous odontogenic tumor
D. All of the above

17. Primary lesion of aphthous stomatitis occurs as:
A. Vesicle B. Bulla
C. Papule D. Blister
18. The cyst with high reoccurrence rate:
A. OKC
B. AOT
C. Globulomaxillary cyst
D. Dentigerous cyst
19. Severe complication of erythema multiforme is called as:
A. Stevens-Johnson syndrome
B. Toxic epidermal necrolysis
C. Both of the above
D. None
20. Ameloblastoma arising from dentigerous cyst is:
A. Mural ameloblastoma
B. Unicystic ameloblastoma
C. Granular ameloblastoma
D. Desmoplastic ameloblastoma
21. Syndrome associated with odontogenic keratocyst is:
A. Gardner's syndrome
B. Gorlin-Goltz syndrome
C. Grinspan syndrome
D. Goldenhar's syndrome
22. Non-inflammatory, non-neoplastic enlargement of the salivary gland is called as:
A. Sialorchitis B. Sialolithiasis
C. Sialadenitis D. Sialosis
23. Odontoma which resembles to the normal teeth is called as:
A. Composite compound odontoma
B. Composite complex odontoma
C. Comminuted odontoma
D. None
24. Multiple odontogenic keratocyst is found in:
A. Marfan's syndrome
B. Ehlers-Danlos syndrome
C. Noonan's syndrome
D. All of the above
25. Focal sclerosing osteomyelitis is associated with:
A. Vital tooth
B. Non-vital tooth
C. Traumatic tooth
D. Cracked tooth
26. Split papule, condyloma latum is seen in:
A. Primary syphilis
B. Secondary syphilis
C. Tertiary syphilis
D. Congenital syphilis
27. Most aggressive type of ameloblastoma, histologically is:
A. Plexiform ameloblastoma
B. Follicular ameloblastoma
C. Basal cell ameloblastoma
D. Granular ameloblastoma
28. All of the following radiographs are taken to diagnose the para nasal sinus pathology *except*:
A. Water's view
B. Caldwell projection
C. Panoramic
D. Submentovertex
29. Leucic glossitis or chronic superficial interstitial glossitis is caused by:
A. Mycobacterium tuberculosis
B. Treponema palladium
C. Actinomycosis
D. Epstein-Barr virus
30. Heerfordt's syndrome is associated with all *except*:
A. Submandibular swelling
B. Uveitis
C. Parotid enlargement
D. Facial palsy
31. Disease causing dermatitis, diarrhea and dementia is:
A. Vit B₁₂ deficiency B. Pellagra
C. Vit B₅ deficiency D. Vit B₆ deficiency
32. A self-healing non-neoplastic inflammatory reaction of salivary gland that mimics a salivary gland neoplasm:
A. Epidermoid carcinoma
B. Pleomorphic adenoma
C. Cystadenoma lymphomatosum
D. Necrotizing sialometaplasia
33. Thrombocytopenic purpura occurs due to:
A. Quantitative defect of platelets
B. Qualitative defects of platelets
C. Both of the above
D. Vit C deficiency
34. Herpes ulcer are seen in:
A. Moveable mucosa
B. Mucosa bound to periosteum
C. Tongue
D. Lips
35. 'Target' or 'bull eye' lesion is typical of:
A. Erythema multiforme
B. Pemphigus
C. Bullous pemphigoid
D. Lichen planus
36. Gingiva is most commonly affected by deficiency of:
A. Vit A B. Vit C
C. Vit D D. Vit B
37. In osteomalacia there is:
A. Defective osteoid + normal mineralization
B. Normal osteoid + defective mineralization
C. Abnormal osteoid + abnormal mineralization
D. Normal osteoid + demineralization
38. The life threatening blood disorder caused due to drugs:
A. Aplastic anemia
B. Pernicious anemia
C. Hemolytic anemia
D. Thrombocytopenia

39. **Hunter's glossitis is seen in:**
 A. Niacin deficiency
 B. Vit V deficiency
 C. Riboflavin deficiency
 D. Vit B₁₂ deficiency
40. **Vesicles or bulla of erythema multiforme, pemphigus vulgaris are:**
 A. Intraepithelial B. Subepithelial
 C. Supraepithelial D. None
41. **Antischkow cells are found in:**
 A. Pemphigus B. Aphthous
 C. Contact allergy D. Stomatitis
42. **Glandular fever is caused due to:**
 A. Varicella-zoster virus
 B. Paramyxovirus
 C. Epstein-Barr virus
 D. Coxsackie A16 virus
43. **Lumbar lordosis is feature of:**
 A. Pellagra B. Osteomalacia
 C. Osteoporosis D. Rickets
44. **Pemphigus is a:**
 A. Inflammatory disease
 B. Autoimmune disease
 C. Skin disease
 D. Noninflammatory disease
45. **The red blood cell in iron deficiency anemia and thalassemia are typically:**
 A. Macrocytic and normochromic
 B. Microcytic and hypochromic
 C. Normocytic and hypochromic
 D. Normocytic and normochromic
46. **Hyperplastic inflammation of the terminal end of the draining sinus is:**
 A. Parulis B. Actinomycosis
 C. Tuberculosis D. Syphilis
47. **Branchial fistula occurs due to fusion of:**
 A. 1st branchial arch with 6th
 B. 1st branchial arch with 2nd
 C. 1st branchial arch with 5th
 D. 2nd branchial arch with 5th
48. **An unusual prominence of premaxilla is seen in:**
 A. Acromegaly B. Paget's disease
 C. Fibrous dysplasia D. Thalassemia
49. **Wash leather slough on the floor of the ulcer is pathognomonic of:**
 A. Tuberculosis ulcer
 B. Aphthous ulcer
 C. Gummatous ulcer
 D. Malignant ulcer
50. **The protein content is less than 4 gm% in:**
 A. Keratocyst
 B. Dentigerous cyst
 C. Radicular cyst
 D. Primordial cyst
51. **Test done for small swelling:**
 A. Patch test
 B. Paget's test
 C. Fluctuation test
 D. Fluid thrill
52. **The most common cause for submaxillary swelling:**
 A. Mumps
 B. Lymphadenopathy
 C. Cellulitis
 D. Periapical abscess
53. **Hemophilia A is due to deficiency of:**
 A. Factor VIII
 B. Factor IX
 C. Factor VII
 D. Platelet deficiency
54. **Swellings that are reducible are:**
 A. Meningocele
 B. Hemangioma
 C. Ranula
 D. Subdermoid cyst
55. **A congenital disease characterized by pancytopenia, bone marrow hypoplasia and congenital anomalies is suggestive of:**
 A. Aplastic anemia
 B. Fanconi anemia
 C. Thrombocytopenia
 D. Pernicious anemia
56. **Pathergy test is diagnostic criteria of:**
 A. Reiters syndrome
 B. Behcet's syndrome
 C. Stevens-Johnson syndrome
 D. Lyell's disease
57. **The temperature that remains above normal throughout the day and fluctuates more than 1 degree in 24 hours is:**
 A. Intermittent fever
 B. Remittent fever
 C. Low grade fever
 D. Continuous fever
58. **Patient suspecting of suffering from infectious mononucleosis which laboratory test should be advised to confirm the diagnosis:**
 A. Dick test
 B. Paul-Bunnell test
 C. Rose Bengal test
 D. Shick test
59. **In sickle cell trait only..... of HbA is replaced by HbS:**
 A. 25%
 B. 50%
 C. 75%
 D. 35%
60. **Gumma is present in:**
 A. Primary syphilis
 B. Secondary syphilis
 C. Tertiary syphilis
 D. Congenital syphilis

61. 'Suttons' disease is other wise commonly called as:
A. Major aphthous stomatitis
B. Minor aphthous stomatitis
C. Recurrent aphthous stomatitis
D. Herpes labialis
62. Ramsay hunt syndrome is caused due to:
A. Coxsackievirus
B. Herpes-zoster virus
C. Herpes simplex
D. Bacterial infection
63. Chvostek's sign is seen in:
A. Hypoparathyroidism
B. Hyperparathyroidism
C. Hypothyroidism
D. Hyperthyroidism
64. Enamel hypoplasia involving incisal edges of the anterior teeth and middle 3rd of deciduous cuspid and 1st molar resulting in a characteristic ring like defect known as 'Rh hump' is characteristic of:
A. Dental fluorosis
B. Erythroblastosis fetalis
C. Turner's syndrome
D. Pernicious anemia
65. Eyes looking toward heaven is a typical appearance seen in:
A. Cherubism
B. Scleroderma
C. SLE
D. Cushing syndrome
66. Mediterranean anemia is commonly known as:
A. Aplastic anemia
B. Thalassemia
C. Pernicious anemia
D. Iron deficiency anemia
67. Bull teeth is seen in:
A. Turner's syndrome
B. Erythema multiforme
C. Taurodontism
D. Dentin dysplasia
68. In geographic tongue there desquamation of:
A. Filiform papillae
B. Fungiform papillae
C. Circumvallate papillae
D. Foliate papillae
69. Kaposi sarcoma is caused by:
A. HSV 2
B. HSV 4
C. HSV 8
D. HTL virus
70. The triad of the mumps consists of epidemic parotitis, orchitis-oophoritis and:
A. Epididymitis
B. Encephalitis
C. Pancreatitis
D. None of the above
71. Cylindroma is:
A. Pindborg's tumor
B. Warthin's tumor
C. Adenoid cystic carcinoma
D. Adenolymphoma
72. 'Lava flowing around the boulders' is seen in:
A. Type 2 dentin dysplasia
B. Type 1 dentin dysplasia
C. Type 3 dentin dysplasia
D. Both A and C
73. Most common leukemia found in children is:
A. ALL
B. CLL
C. AML
D. CML
74. Characteristic appearance of Sjögren's syndrome in sialograms:
A. Cherry blossom
B. Fruitless tree
C. Driven snow
D. Tennis racket
75. Multiple bone involvement, café au lait pigmentation and endocrine disturbance is associated with:
A. Albright's syndrome
B. Jaffe's syndrome
C. Addison's disease
D. Paget's disease
76. Intracellular inclusion bodies detected in herpes simplex infection are called as:
A. Negri bodies
B. Civatte bodies
C. Lipschutz bodies
D. Ruston bodies
77. Leukoplakia type of candidiasis associated with oral epidermoid carcinoma:
A. Acute atrophic
B. Chronic atrophic
C. Chronic hyperplastic
D. Thrush
78. Mikulicz's disease is an:
A. Bacterial infection
B. Viral infection
C. Inflammatory infection
D. Autoimmune disease
79. Cryptococcosis is also known as:
A. Valley disease
B. Torulosis
C. Moniliasis
D. Mucormycosis
80. Id reaction is associated with:
A. Aphthous
B. Herpetic stomatitis
C. Syphilis
D. Candidiasis

81. Christmas disease is due to deficiency of:
 A. Hageman factor
 B. Platelets
 C. Plasma thromboplastin antecedent
 D. Plasma thromplastin component
82. Etiological actor for megaloblastic anemia is:
 A. Vit B₁₂ deficiency
 B. Vit B₆ deficiency
 C. Folate deficiency
 D. Both A and C
83. Candidial infection is seen in all except:
 A. Median rhomboid glossitis
 B. Oral thrush
 C. Geographic tongue
 D. Denture stomatitis
84. Hutchinson's sign is seen in:
 A. Congenital syphilis
 B. Leprosy
 C. Herpes-zoster
 D. Tuberculosis
85. Rigidity of facial muscles producing typical "risus sardonicus" is observed:
 A. Tetanus
 B. MPDS
 C. Bell's palsy
 D. Tetany
86. Most common site for hemangioma tumor is:
 A. Tongue
 B. Lip
 C. Palate
 D. Skin
87. Rubella refers to:
 A. Measles
 B. Smallpox
 C. Chickenpox
 D. German measles
88. Tuberculous infection of submaxillary and cervical lymph node is called as:
 A. Lupus vulgaris
 B. Scrofula
 C. Pott's disease
 D. None of the above
89. Verruciform xanthoma is a variant of:
 A. Histiocytosis-X
 B. Histiocytosis-Y
 C. Eosinophilic granuloma
 D. Achondroplasia
90. Schillings test is done for:
 A. Scarlet fever
 B. Pellagra
 C. Niacin deficiency
 D. B₁₂ deficiency
91. Mumps is caused by:
 A. Paramyxovirus
 B. Pox virus
 C. E-B virus
 D. Orthomyxovirus
92. Cafe' au lait spots are seen in all of the following disease except:
 A. Neurofibromatosis
 B. Fibrous dysplasia
 C. Peutz-Jeghers syndrome
 D. Addison's disease
93. All are the forms of lichen planus except:
 A. Erosive
 B. Atrophic
 C. Hypertrophic
 D. Verrucous
94. Frey's syndrome patient exhibit gustatory sweating and flushing due to damage to:
 A. Chorda tympani nerve
 B. Auriculotemporal nerve
 C. Facial nerve
 D. Facial artery
95. Petrified men is seen in:
 A. MPDS
 B. Myositis ossificans
 C. Trismus
 D. Nasopharyngeal neuralgia
96. Nikolsky's sign is not seen in:
 A. Pemphigus
 B. Hailey-Hailey disease
 C. Epidermolysis bullosa
 D. Lupus erythematosus
97. Hypersensitivity reaction in Steven-Johnson syndrome:
 A. Type 1
 B. Type 2
 C. Type 3
 D. Type 4
98. Koebner phenomenon is seen with:
 A. Erythema multiforme
 B. Discoid lupus erythematosus
 C. Pemphigoid
 D. Lichen planus
99. Gargoyle cells are seen in:
 A. Hurler syndrome
 B. Mucoepidermoid carcinoma
 C. Gingival cyst of adult
 D. Lymphoma
100. Genuiculate neuralgia occurs due to involvement of nerve:
 A. VII
 B. V
 C. X
 D. IX
101. Mumps are characterized as:
 A. Acute non-suppurative sialadenitis
 B. Acute suppurative sialadenitis
 C. Chronic non-suppurative sialadenitis
 D. Chronic suppurative sialadenitis
102. Osteopetrosis shows lab findings:
 A. Increased serum alkaline phosphatase
 B. Decreased serum calcium level
 C. Increased serum acid phosphatase
 D. Decreased serum alkaline phosphatase

- 103. Xerostomia is seen:**
A. Sjögren's syndrome
B. Patient on anticholinergic drugs
C. Patient on radiation therapy
D. All of the above
- 104. Lesion arising due to rupture of salivary duct:**
A. Ranula
B. Mucocele
C. Sialosis
D. Atresia
- 105. Blue sclera, brittle bone opalescent dentin is a sign and symptoms suggestive of:**
A. Paget's disease
B. Osteogenesis imperfecta
C. Marfan's syndrome
D. Osteopetrosis
- 106. Hailey-Hailey disease shows characteristic histological feature:**
A. Basilar hypertrophy
B. No basement membrane
C. Dilapidated brick wall effect
D. Coagulative necrosis
- 107. Pharyngeal pain, dysphagia, sore throat, glossodynia due to elongated styloid process is feature of:**
A. Horner's syndrome
B. Fothergill's disease
C. Frey's syndrome
D. Eagle's syndrome
- 108. Ground glass appearance is a radiographic feature of:**
A. Fibrous dysplasia
B. Hyperparathyroidism
C. Both of the above
D. None of the above
- 109. The gland that can be palpated bimanually is:**
A. Submandibular
B. Sublingual
C. Parotid
D. Sublingual and parotid both
- 110. Serum alkaline phosphatase is increased to 250 Bodansky units in:**
A. Fibrous dysplasia
B. Paget's diseases
C. Osteopetrosis
D. Cherubism
- 111. Triad of Behçet's syndrome consists of all except:**
A. Recurrent oral ulcer
B. Arthritis
C. Recurrent genital ulcers
D. Eye lesions
- 112. Most common neoplasm of major and minor salivary gland:**
A. Warthin's tumor
B. Mucoepidermoid carcinoma
C. Necrotizing metaplasia
D. Cylindroma
- 113. Histologically pemphigus shows:**
A. Acanthosis
B. Acantholysis
C. Keratin pearl
D. Civatte bodies
- 114. Cherubism is a:**
A. Bilateral lesion
B. Unilateral lesion
C. Shows early eruption of permanent teeth
D. Seen at the age of 20-25 years
- 115. Post-cricoid's carcinoma is associated with:**
A. Pernicious anemia
B. Iron deficiency anemia
C. B₁₂ deficiency
D. Aplastic anemia
- 116. von Willebrand's disease shows:**
A. Prolonged bleeding time, normal clotting time
B. Normal bleeding, prolonged clotting time
C. Prolonged bleeding and prolonged clotting time
D. Normal bleeding and normal clotting time
- 117. Biopsy of intact bullae and vesicles done in pemphigus should be of:**
A. Not less than 6 hr
B. More than 12 hr
C. Less than 24 hr
D. More than 48 hr
- 118. Necrotizing sialometaplasia a benign inflammatory lesion occurs most commonly in the sites:**
A. Buccal mucosa
B. Palate
C. Tongue
D. Gingiva
- 119. Patient shows the clinical picture of enlarged both maxilla and mandible with biochemical findings showing increased alkaline phosphatase level and radiographs reveals cotton wool appearance. The most probable diagnosis is:**
A. Monostotic fibrous dysplasia
B. Osteogenic imperfecta
C. Paget's disease
D. Leontiasis ossea
- 120. Localized form of epidermolysis bullosa showing recurrent bullous eruption of hands and feet is seen in:**
A. Herlitz's disease
B. Weber-Cockayne syndrome
C. Epidermolysis bullosa acquista
D. Epidermolysis bullosa latalis
- 121. Nikolsky's phenomenon is a pathognomic sign of:**
A. Pemphigus vulgaris
B. Epidermolysis bullosa
C. Bullosa pemphigus
D. Both A and B
- 122. Epidermolysis bullosa simplex is:**
A. Autoimmune disease
B. Autosomal dominant
C. Autosomal recessive
D. X-linked disease

- 123. Brazilian pemphigus is a mild endemic form of:**
 A. Pemphigus erythematous
 B. Pemphigus vegetans
 C. Pemphigus vulgaris
 D. Pemphigus foliaceus
- 124. Halitosis is caused by all except:**
 A. Periodontal disease
 B. Diabetes
 C. Decayed tooth
 D. Hypertension/Hemangioma
- 125. Irregularly irregular pulse is seen in:**
 A. Atrial fibrillation
 B. Ventricular fibrillation
 C. Ventricular failure
 D. Patent ductus arteriosus
- 126. Clubbing a bullous enlargement of soft part of terminal phalanges of nail positive in:**
 A. Infective endocarditis
 B. Hypothyroidism
 C. Left ventricular failure
 D. None of above
- 127. Life saving drug of choice for the management of Steven-Johnson syndrome:**
 A. Azathioprine
 B. Antiviral drugs
 C. Dapsone
 D. Corticosteroids
- 128. Ramsay hunt syndrome is associated with complication of:**
 A. Shingles
 B. Varicella zoster
 C. Erythema multiforme
 D. Herpangina
- 129. Epidemic disease causing ulcerative lesion restricted to posterior portion of pharynx:**
 A. Herpes simplex
 B. Shingles
 C. Herpangina
 D. Acute lymphonodular pharyngitis
- 130. Intestinal polyp is mainly found in:**
 A. Addison's disease
 B. Peutz-Jeghers syndrome
 C. Hemochromatosis
 D. Neurofibromatosis
- 131. Pathological wearing away of the tooth substance through abnormal mechanical process called as:**
 A. Attrition
 B. Erosion
 C. Abrasion
 D. Abfraction
- 132. Root caries involves commonly:**
 A. Enamel and dentine
 B. Enamel, dentin and pulp
 C. Cementum and dentin
 D. Dentin and pulp
- 133. Stress lesion is another name for:**
 A. Attrition
 B. Abrasion
 C. Erosion
 D. Abfraction
- 134. Bronze diabetes is commonly called as:**
 A. Weber syndrome
 B. Gardener syndrome
 C. Addison's disease
 D. Hemochromatosis
- 135. Pink spot in the roots of the tooth is seen in:**
 A. Internal resorption
 B. Acute pulpitis
 C. Dentinal sclerosis
 D. External resorption
- 136. All of the muscles of the tongue is supplied by hypoglossal except:**
 A. Genioglossus
 B. Hypoglossal
 C. Styloglossus
 D. Palatoglossal
- 137. Deposition of excessive amount of the cementum on the root surface is known as:**
 A. Hypercementosis
 B. Cementicles
 C. Cementum hyperplasia
 D. Both A and C
- 138. Liver cirrhosis, diabetes, cardiac failure and bronze skin are the tetrad mainly seen in:**
 A. Hemochromatosis
 B. Neurofibromatosis
 C. Chronic adrenal insufficiency
 D. Hepatitis
- 139. Amalgam tattoo is an example of:**
 A. Accidental pigmentation
 B. Iatrogenic pigmentation
 C. Endogenous pigmentation
 D. Pigmentation due to drugs
- 140. In order to detect caries radiographically, net mineral loss of the tooth should be:**
 A. Exceed 20 to 30%
 B. Upto 10-20%
 C. More than 40%
 D. 30 to 40%
- 141. Transparent dentin is the term used for:**
 A. Secondary dentin
 B. Dentinal sclerosis
 C. Irregular dentin
 D. Tertiary dentin
- 142. Benign migratory glossitis is called:**
 A. Geographic tongue
 B. Wandering tongue
 C. Glossitis areata exfoliativa
 D. Erythema migrans
 E. All of the above

143. Zone of dentinal sclerosis characterized by deposition of the calcium salt in dentinal tubules in dentin caries is identified as:
A. Zone 1
B. Zone 2
C. Zone 3
D. Zone 4
144. Plumbism is due to:
A. Mercury poisoning
B. Lead poisoning
C. Bismuth poisoning
D. Silver poisoning
145. Dental caries is mainly caused due to:
A. Streptococcus mutans
B. Actinomyces viscosus
C. L. acidophilus
D. Staphylococcus
146. Paper test is done:
A. Allergy
B. Pigmentation
C. Swelling
D. Vit deficiency
147. Cupping in dentin of the tooth is due to:
A. Abrasive lesion
B. Attrition
C. Abfraction
D. Erosive lesion
148. Glossopharyngeal nerve is the nerve for:
A. General sensation for the anterior 2/3rd of the tongue
B. Special sensation for anterior 2/3rd of the tongue
C. General sensation for posterior 1/3rd
D. Special sensation for posterior 1/3rd
149. Cleft palate is associated with all the syndrome except:
A. Pierre-Robin syndrome
B. Down's syndrome
C. Apert's syndrome
D. Ascher's syndrome
150. Which of the radiographs are indicated for the diagnosis of the proximal caries?
A. IOPA
B. Bite wing radiographs
C. Occlusal
D. OPG
151. Bluish green pigmentation on gingiva and teeth called Clapton line is caused due to:
A. Lead
B. Copper
C. Chromium
D. Mercury
152. pH of the dental plaque is critical threshold for demineralization to create dental caries is:
A. pH 5.4
B. pH 5.5
C. pH 5.6
D. pH 5.7
153. Regressive changes that occurs in the teeth that starts from inner surface to outer of the teeth:
A. Abfraction
B. Attrition
C. Erosion
D. Internal resorption
154. Extensibility of the tongue to touch the lip of the nose is termed as:
A. Battle's sign
B. Gorlin's sign
C. Chvostek's sign
D. Bon-bon sign
155. Swift is commonly known as:
A. Silver toxicity
B. Bismuth toxicity
C. Mercurial toxicity
D. Lead toxicity
156. All of the caries are well detected radiographically except:
A. Incipient caries
B. Moderate caries
C. Advanced caries
D. Severe caries
157. Thyroid gland in the embryo form ventral floor of pharynx by means of:
A. Ectodermal evagination of the diverticulum's
B. Endodermal evagination of the diverticulum's
C. Ectodermal invagination of the diverticulum's
D. Endodermal invagination of the diverticulum's
158. Fissured tongue has all other following terms except:
A. Scrotal tongue
B. Lingua villosa
C. Plicated tongue
D. Lingua dissecta
159. Pierre-Robin syndrome is the combination of the disease except:
A. Micrognathia
B. Cleft palate
C. Glossoptosis
D. Macroglossia
160. Systemic disease not causing gingival enlargement:
A. Leukemia
B. Crohn's disease
C. Orofacial angiomatosis
D. Diabetes
161. Greenstick fracture are seen in:
A. Newborn
B. Children
C. Youngsters
D. Adult
162. Sharpened pencil appearance of the condyle is seen in:
A. Osteoarthritis
B. Rheumatic fever
C. Rheumatoid arthritis
D. Osteoporosis

163. Maxillary sinus is best visualized by:
 A. Periapical radiographs
 B. Waters view
 C. Submentovertex
 D. Lateral skull view
164. Physical medication used in management of MPDS are all *except*:
 A. Oral myofunctional therapy
 B. Diathermy and ultrasound
 C. Electrical stimulation
 D. Voluntary resistance
165. Stiff joint is term used for:
 A. Internal derangement
 B. Ankylosing spondylitis
 C. Ankylosis
 D. Infective arthritis
166. In edentulous patient bilateral condylar fracture is treated by:
 A. Using gunning splint
 B. Arch bar
 C. Arch wire
 D. Only immobilization in normal position
167. Subcutaneous nodules mainly seen in:
 A. Psoriatic arthritis
 B. Rheumatic arthritis
 C. Osteoarthritis
 D. Klinefelter syndrome
168. Minute areas of degeneration filled with fibrous tissues just below the bony surface of the condyle in osteoarthritis called as:
 A. Lipping of the bone
 B. Ely's cyst
 C. Osteophyte
 D. Eburnation
169. Good transillumination of sinus indicates:
 A. Presence of pus in sinus
 B. Presence of solid lesion in sinus
 C. Mucosal thickening of the sinus
 D. Presence of air filled sinus
170. Malignant tumor of the cartilage:
 A. Osteochondroma
 B. Chondrosarcoma
 C. Synovial chondromatosis
 D. Osteoma
171. Laskin's cardinal sign involves the following features except:
 A. Unilateral pain in preauricular area
 B. Muscle tenderness
 C. Masticatory muscle spasm
 D. Limited jaw movement
172. Irregular shaped reddish area of depapillation and thinning of the dorsal tongue epithelium surrounded by the zone of regenerative papillae is shown in:
 A. Fissured tongue
 B. Median rhomboid glossitis
 C. Benign migratory glossitis
 D. Hairy tongue
173. Color of the pigmentation caused due to hemosiderin is:
 A. Blue
 B. Brown
 C. Grey
 D. Black
174. Dental caries that is difficult to differentiate radiographically:
 A. Occlusal caries
 B. Buccal caries
 C. Mesial caries
 D. Distal caries
175. Failure to unite palatal process due to disturbances in normal fusion of the palatal shelves causes:
 A. Only cleft of hard palate
 B. Both cleft of hard and soft palate
 C. Cleft of lip, hard and soft palate
 D. Cleft of hard, soft palate and uvula
176. Phlebectasia is the term used for:
 A. Lingual varices
 B. Varicosity
 C. Both A and B
 D. None of the above
177. Fibrotic gingival enlargement is seen in all except:
 A. Due to drug cyclosporine
 B. Due to nifedipine
 C. Granuloma pyogenicum
 D. Idiopathic
178. Parade ground fracture involves:
 A. Unilateral condylar fracture
 B. Bilateral condylar fracture
 C. Mandibular body fracture
 D. Ramus and angle of mandibular fracture
179. Corticosteroids are contraindicated in:
 A. Herpes simplex
 B. Mandibular osteoarthritis
 C. Submucous fibrosis
 D. Lichen planus
180. Antrum of highmore is the term used for:
 A. Sphenoid sinus
 B. Cavernous sinus
 C. Maxillary sinus
 D. Ethmoidal sinus
181. Gout is characterized with following except:
 A. Joint pain
 B. Swelling over the joint
 C. Elevated blood uric acid
 D. Multiple bone fracture
182. Beauty vitamin is another name for:
 A. Vit B₁
 B. Vit B₆
 C. Vit B₁₂
 D. Vit B₂
183. Macrognathia seen in:
 A. Robin's syndrome
 B. Turner's syndrome
 C. Leontiasis ossea
 D. Marfan's syndrome

184. Electrical burns causes tissues necrosis is characterized by:
A. Coagulation of the protein
B. Destruction of the neural tissues
C. Liquefaction of the fat
D. Vaporization of the tissues fluids
185. Dislocation and disarticulation of the teeth which is abnormally mobile and are displaced called as:
A. Concussion
B. Avulsion
C. Luxation
D. Contusion
186. Dry socket is referred to:
A. Postoperative osteitis
B. Alveolalgia
C. Focal osteomyelitis
D. All of the above
187. Facial hemiatrophy is known as:
A. Marfan's syndrome
B. Parry-Romberg syndrome
C. Hallerman-Steriff syndrome
D. Crouzon's syndrome
188. Gummy smile seen mostly in case of:
A. Friedreich disease
B. Macrognathia
C. Micrognathia
D. Mandibulofacial dystosis
189. Diabetes is associated with:
A. Hand-Schuller-Christian
B. Lichen planus
C. None of the above
D. Both A and B
190. Blow out fracture is due:
A. Calcification in the sinus
B. Increased in intraorbital pressure
C. Trauma to the chin
D. All of the above
191. Taurodontism is associated with:
A. Crouzon;s syndrome
B. Klinefelter's syndrome
C. Binder syndrome
D. Treacher-Collins syndrome
192. Inflammation of the mucosa of paranasal sinus is referred as:
A. Pansinusitis
B. Sinusitis
C. Antroliths
D. Maxillary sinusitis
193. Internal derangement occurs due to trauma from malocclusion results in the spasm of:
A. Temporalis
B. Lateral pterygoid
C. Medial pterygoid
D. Masseter
194. Macroglossia can be result of:
A. Lymphangioma
B. Neurofibroma
C. Lipoid proteinosis
D. All of the above
195. In unilateral ankylosis patient's face is deviated towards:
A. Affected side
B. Unaffected side
C. Undeviated
D. None of the above
196. Erosion of the bone found in which stage of the rheumatoid arthritis:
A. Stage I
B. Stage II
C. Stage III
D. Stage IV
197. The gingival fibers that helps to maintain the position of free gingiva:
A. Dento-gingival
B. Alveola gingival
C. Circular fibers
D. Transseptal fibers
198. ANUG is caused by:
A. Only spirochetes
B. Both fusiform bacilli and spirochetes
C. Fusiform bacilli, spirochetes and bacteroid intermedius
D. Spirochetes and bacteriod intermedius
199. Carcinoma of the tip of the tongue is drained in:
A. Submental lymph nodes
B. Jugulo-omohyoid node
C. Submandibular node
D. Both A and B
200. Volkmann's chelitis is most severe suppurative form of:
A. Granulomatous chelitis
B. Angular chelitis
C. Actinic chelitis
D. Glandular chelitis
201. 'Rule of ten' is used for the management of cleft lip involves the following criteria *except*:
A. Age
B. Body weight
C. Body fluid
D. Hb%
202. Miescher's syndrome is also known as:
A. Glandular chelitis
B. Granulomatous chelitis
C. Plasma cell chelitis
D. Exfoliative chelitis
203. A patient with Bell's palsy has.....palsy:
A. Upper motor neuron nerve
B. Upper motor neuron VII nerve
C. Lower motor neuron V nerve
D. Lower motor neuron VII nerve

204. Characteristic 'tram line' calcifications in the skull radiographs is observed in:
 A. Cleidocranial dysostosis
 B. Sturge-Weber syndrome
 C. Paget's disease
 D. Maccune-Albright syndrome
205. Which of the following appears to arise from the sunlight?:
 A. Basal cell carcinoma B. Ewing's sarcoma
 C. Kaposi sarcoma D. Verruca vulgaris
206. A hamartoma is:
 A. Any collection of the blood clot
 B. A hemorrhagic cyst of the thigh
 C. Developmental malformation
 D. A tumor of soft tissues
207. 'Rubber man' appearance seen in:
 A. Marfan's syndrome
 B. Gorham syndrome
 C. Ehlers-Danlos syndrome
 D. First arch syndrome
208. Human immunodeficiency virus binds to macrophages having:
 A. CD4 molecule
 B. CD4 and CXCR molecule
 C. CD4 and CCR5
 D. CXCR and CCR5 molecule
209. Which of the following conditions is the most common complication of radioiodine treatment of Grave's disease?:
 A. Thyroid storm B. Subacute thyroiditis
 C. Thyroid cancer D. Hypothyroidism
210. Microscopic appearance of the geographic tongue resemble:
 A. Lichen planus
 B. Lupus erythematosus
 C. Erythema multiforme
 D. Psoriasis
211. Which of the following test is most specific test to diagnose syphilis?
 A. VDRL test B. Wassermann test
 C. RPR test D. FTA-ABS
212. Hemochromatosis presents with all except:
 A. Micronodular cirrhosis
 B. Diabetes mellitus
 C. Skin pigmentation
 D. Hepatitis
213. Strawberry tongue is seen in:
 A. Scarlet fever
 B. Wegner's granulomatosis
 C. Midline lethal granuloma
 D. Sarcoidosis
214. Among the following pain theories, the most accepted theory is:
 A. Specificity theory
 B. Pattern theory
 C. Gate control theory
 D. Calcium displacement theory
215. Definite loss of lamina dura is seen in:
 A. Secondary hypercemia
 B. Hyperparathyroidism
 C. Primary hyperthyroidism
 D. Secondary hypothyroidism
216. Treatment of choice for mixed parotid tumor is:
 A. Enucleation
 B. Superficial parotidectomy
 C. Radical parotidectomy
 D. Radiation
217. Which one given below is a DNA virus:
 A. Poliovirus B. Adenovirus
 C. Astor viridae D. Hepatitis-A virus
218. The Philadelphia chromosome is a feature of:
 A. Luekemoid reaction
 B. Chronic myeloid leukemia
 C. Acute lymphoblastic leukemia
 D. Chronic lymphocytic leukemia
219. Ranula is a:
 A. Retention cyst B. Implantation
 C. Begin tumor D. Malignant tumor
220. Failure of descent of thyroid analouge can be seen in the tongue:
 A. In anterior 2/3rd of dorsal aspect
 B. In posterior 1/3rd of dorsal aspect
 C. Near the base of the tongue close to foramen caecum
 D. In anterior 2/3rd of inferior surface
221. Most common salivary gland tumor arising in the jaws:
 A. Pleomorphic adenoma
 B. Adenoid cystic carcinoma
 C. Mucoepidermoid carcinoma
 D. Acinic cell carcinoma
222. Kussmaul's respiration occurs in response to:
 A. Decrease in pH of the blood
 B. Increase in pH of the blood
 C. Obstructive pulmonary disease
 D. Carbon monoxide poisoning
223. Enamel hypoplasia occurring from the local infection is called:
 A. Amelogenesis dysplasia
 B. Plumbism
 C. Dental fluorosis
 D. Turner's teeth
224. The absence of clavicle are seen in:
 A. Cleidocranial dysplasia
 B. Osteogenesis imperfecta
 C. Sturge-Weber anomaly
 D. Idiopathic bone cavities
225. The stabbing nature of the pain in trigeminal neuralgia mimic the pain caused by:
 A. A cracked tooth
 B. Acute reversible pulpitis
 C. Acute irreversible pulpitis
 D. Acute apical periodontitis

226. Sialoliths are the stones found in salivary duct and duct is mainly composed of:
A. Hydroxyapatite
B. Potassium chloride
C. Unknown compounds of phosphate
D. Calcium chloride
227. 'Denture sore mouth' are also known as:
A. Acute pseudomembranous candidiasis
B. Acute atrophic candidiasis
C. Chronic atrophic candidiasis
D. Chronic hyperplastic candidiasis
228. The virus responsible to cause Hodgkin's lymphoma:
A. Herpes virus
B. E-B virus
C. Coxsackievirus
D. HHV6 virus
229. Horton's syndrome is:
A. Trigeminal neuralgia
B. Sphenopalatine neuralgia
C. Parkinsonism
D. None
230. Shingles of the geniculate ganglion with ear eruption and facial paralysis is termed as:
A. Peutz-Jeghers syndrome
B. Melkersson-Rosenthal syndrome
C. Ramsay Hunt syndrome
D. Gardner's syndrome
231. Hot potato voice is characteristically seen in:
A. Pterygomandibular space infection
B. Retropharyngeal space infection
C. Pretracheal space infection
D. Lateral pharyngeal space infection
232. Acute pyogenic infection produces:
A. Leukopenia
B. Leukocytosis
C. Neutropenia
D. Lymphopenia
233. Hanging drop sign is best seen in:
A. Water's projection
B. Orthopantomogram
C. Submentovertex
D. Occlusal view
234. A fractured mandibular condyle is displaced by the action of:
A. Temporalis
B. Masseter
C. Lateral pterygoid
D. Medial pterygoid
235. In hemolytic anemia the urobilinogen level in the blood would:
A. Increase
B. Absent
C. Decrease
D. Mildly decrease
236. Epstein-Barr virus has been implicated in the etiology of:
A. Oral Lichen planus
B. Oral hairy leukoplakia
C. Oral hairy black tongue
D. Oral melanoplakia
237. A 20 years female came to the clinic with severe pain and redness over the dorsum of the foot. Past history of severe abdominal pain episodes were present. Peripheral smear showed anemia with presence of poikilocytes your likely diagnosis is:
A. Hemoglobin C disease
B. Thalassemia
C. Sickle cell anemia
D. G6PD deficiency
238. In young permanent teeth the best method of sensitivity testing for the traumatized teeth is carbon dioxide snow which can go up to temperature of:
A. -20°C
B. -30°C
C. -40°C
D. -78°C
239. Most common dislocation of the TMJ is:
A. Anterior
B. Lateral
C. Posterior
D. Medial
240. Uniform widening of the PDL at the expense of the adjacent bone occurs in:
A. Langerhan's cell histiocytosis
B. von Recklinghausen's disease
C. Scleroderma
D. Osteoporosis
241. The nerves commonly affected in shingles are C3, T5, L1, L2 and:
A. 1st division of trigeminal nerve
B. 2nd division of trigeminal nerve
C. 3rd division of trigeminal nerve
D. Facial nerve
242. Fibromatosis gingiva is inherited as:
A. Autosomal dominant
B. Autosomal recessive
C. Both A and B
D. None
243. Synonyms used for necrotizing ulcerative gingivitis is all except:
A. Vincent infection
B. Trench mouth
C. Acute ulceromembranous gingivitis
D. Desquamative gingivitis
244. Most common sign of trauma from occlusion:
A. Occlusal facet
B. Drifting of the teeth
C. Increased mobility of the teeth
D. Gingival bleeding

- 245. Rose waaler test is used to diagnose:**
 A. Rheumatic fever
 B. Osteoarthritis
 C. Rheumatoid arthritis
 D. Osteopetrosis
- 246. Reimplantation of tooth is treatment can be done in case of:**
 A. Concussion
 B. Avulsion
 C. Luxation
 D. Extrusion
- 247. Concrecence occurs:**
 A. After root formation
 B. After crown formation
 C. During crown formation
 D. After complete eruption of tooth
- 248. Talon's cusp arises from:**
 A. Palatal surface
 B. Occlusal surface
 C. Labial surface
 D. Cervical region
- 249. Emphysema is due to:**
 A. Presence of gas
 B. Presence of pus
 C. Presence of blood
 D. Presence of watery fluid
- 250. In Ellis and Davey's classification, displacement of tooth without crown or root fracture includes in:**
 A. Class V
 B. Class VI
 C. Class VII
 D. Class VIII
- 251. Fusion involves union of:**
 A. Only crown of teeth
 B. Only roots of tooth
 C. Both crown and roots of teeth
 D. None of the above
- 252. The most common facial fracture is:**
 A. Maxillary fracture
 B. Mandibular fracture
 C. Zygomatic fracture
 D. Nasal bone fracture
- 253. 'Hanging drop appearance' into antrum seen in:**
 A. Zygomatic complex fracture
 B. Blow-out fracture
 C. Sinus contusion
 D. Squamous cell carcinoma of the antrum
- 254. Exuberent development of fourth lobe gives rise to:**
 A. Supernumerary tooth
 B. Enamel pearl
 C. Bolk cusp
 D. Talon's cusp
- 255. Dens in dent' is due to:**
 A. Focal growth retardation
 B. Active proliferation of enamel organ
 C. Increased intravascular pressure
 D. All the above
- 256. Dilaceration seen mostly in:**
 A. Maxillary 1st molar
 B. Mandibular 1st molar
 C. Maxillary incisor
 D. Mandibular incisors
- 257. In unilateral ankylosis:**
 A. Chin retracted towards affected side
 B. Chin retracted towards unaffected side
 C. Chin is in midline position
 D. None of above
- 258. Dens Evaginatus is the term referred to:**
 A. Gestant odontome
 B. Bolk cusp
 C. Leong's premolar
 D. Carabelli's cusp
- 259. Following is the self-reducing incomplete dislocation:**
 A. Anterior dislocation
 B. Subluxation
 C. Central dislocation
 D. Posterior dislocation
- 260. Internal derangement occurs due to:**
 A. Articular surface remodeling
 B. Disc deformation
 C. Displacement of condyle from its position
 D. All of the above
- 261. Enamel pearl occurs most commonly in:**
 A. Trifurcation of maxillary molars
 B. Bifurcation of maxillary premolars
 C. Bifurcation of mandibular molars
 D. Cervical region of incisors
- 262. Dens in dent is also called as:**
 A. Dilated composite odontome
 B. Gestant odontome
 C. Dens invaginatus
 D. All of the above
- 263. Natal teeth may be associated with:**
 A. Paget's disease
 B. Ellis-van Creveld syndrome
 C. Gardener's syndrome
 D. Cleidocranial dysplasia
- 264. Carabelli's cusp is located:**
 A. Mesiopalatally
 B. Distopalatally
 C. Mesiobuccally
 D. Distobuccally
- 265. Which is the most specific test used to eliminate false positive result is:**
 A. ELISA test
 B. Western blot test
 C. Indirect immunofluorescence test
 D. Polymerase chain reaction
- 266. Actinic keratosis commonly seen in:**
 A. Females and black
 B. Males and black
 C. Females and whites
 D. Males and whites

- 267. Rhagades found in:**
A. Angular cheilitis
B. Eczematous cheilitis
C. Contact cheilitis
D. Exfoliative cheilitis
- 268. Punched out lesions occurs in ANUG in:**
A. Stage 2
B. Stage 3
C. Stage 4
D. Stage 1
- 269. In AIDS patient following findings are present except:**
A. Increased number of helper T cells
B. Decreased serum globulin level
C. Decreased ratio of T helper cells to T suppressor cells
D. Increased level of circulating immune complex
- 270. Goldenhar syndrome consists of:**
A. Agenesis of condyle
B. Hyperplasia of condyle
C. Double condyle
D. Condylar hypoplasia
- 271. Osteoarthritis is called as:**
A. Rheumatoid arthritis
B. Degenerative arthritis
C. Psoriatic arthritis
D. All of the above
- 272. Actinic elastosis is:**
A. Solar elastosis
B. Solar cheilosis
C. Actinic keratosis
D. All of the above
- 273. Most common neoplasm associated with AIDS is:**
A. Non-Hodgkin's lymphoma
B. Kaposi sarcoma
C. Hodgkin's lymphoma
D. Squamous cell carcinoma
- 274. Hypoplasia of condyle is not seen in:**
A. Larsen's syndrome
B. Mobius syndrome
C. Oral facial digital syndrome
D. Pierre Robin syndrome
- 275. Blue domed cyst consists of cavity filled with:**
A. Air
B. Blood
C. Watery fluid
D. Pus
- 276. Hemisepta is the bony defect more common on:**
A. Distally
B. Mesially
C. Buccally
D. Lingually
- 277. Most striking feature of juvenile periodontitis is:**
A. Affects incisors and 1st molar
B. Lack of clinical information despite presence of deep pocket
C. Distolabial migration of maxillary incisors
D. All of the above
- 278. Fat soluble vitamin is stored in:**
A. Liver
B. Kidney
C. Colon
D. Gut
- 279. Outward deviation of one of the eye:**
A. Proptosis
B. Strabismus
C. Diplopia
D. None
- 280. Cleidocranial dysplasia is also known as:**
A. Crouzon's disease
B. Friedreich disease
C. Pagets disease
D. Marie and Sainton disease
- 281. Periodontosis is:**
A. Slowly progressive periodontitis
B. Refractory periodontitis
C. Necrotizing ulcerative periodontitis
D. Juvenile periodontitis
- 282. The most common type of odontogenic cyst is:**
A. OKC
B. Dentigerous cyst
C. Primordial cyst
D. CEOC
- 283. Displaced condylar fracture is well demonstrated on:**
A. AP view
B. Lateral projection
C. Both A and B
D. Orthogram
- 284. Gorlin cyst is:**
A. OKC
B. CEOC
C. Radicular cyst
D. Dentigerous cyst
- 285. Fredrich's disease is called as:**
A. Facial hemiatrophy
B. Facial hemihypertrophy
C. Cleidocranial dysplasia
D. Mandibulofacial dysostosis
- 286. Vestigial cyst is:**
A. Median palatal cyst
B. Nasopalatine cyst
C. Nasoalveolar cyst
D. Globulomaxillary cyst
- 287. Down syndrome consists of:**
A. Microdontia
B. Supernumerary teeth
C. Fissured tongue
D. All of the above
- 288. Single tooth germ invaginates resulting in incomplete formation of two teeth having a bifid crown with single root called as:**
A. Tuning
B. Dens invaginatus
C. Concrescence
D. Gemination

289. Delayed eruption of the teeth occurs in all the disease *except*:
- A. Cleidocranial dysplasia
 - B. Rickets
 - C. Cretinism
 - D. Chondroectodermal dysplasia
290. Simple bone cyst is the term used for:
- A. Traumatic bone cyst
 - B. Aneurysmal bone cyst
 - C. Epidermoid cyst
 - D. Globulomaxillary cyst
291. AIDS occurs mostly in:
- A. Homosexual
 - B. Heterosexual
 - C. Intravenous drugs users
 - D. Newborn infants by infected mother
292. Shell teeth appearance is seen radiographically in:
- A. Dentin dysplasia
 - B. Dentinogenesis imperfecta
 - C. Regional odontodysplasia
 - D. Amelogenesis imperfecta
293. Thin white opaque line running across the tooth surface due to fluorosis under:
- A. Score 0
 - B. Score 1
 - C. Score 3
 - D. Score 2
294. Riga fede is a complication of:
- A. Natal teeth
 - B. Distomolar teeth
 - C. Talon cusp
 - D. Peg shaped lateral
295. Snow capped teeth seen in amelogenesis imperfecta due to:
- A. Hypoplasia of enamel
 - B. Hypocalcification of enamel
 - C. Hypomaturation of enamel
 - D. Trauma to tooth
296. Papillion-Lefevre syndrome is inherited as:
- A. Autosomal recessive
 - B. Autosomal dominant
 - C. Autosomal recessive and X-linked
 - D. Autosomal dominant and X-linked
297. Supernumary tooth that erupts ectopically in normal arch is referred to:
- A. Mesiodens
 - B. Para dens
 - C. Peridens
 - D. Distomolar
298. Teeth erupt prematurely during birth is:
- A. Natal teeth
 - B. Neonatal teeth
 - C. Congenital
 - D. All of the above
299. Bird/fish facial appearance occurs commonly in:
- A. Cleidocranial dysplasia
 - B. Paget's disease
 - C. Mandibulofacial dysostosis
 - D. Crouzon's disease
300. The 'prow of boat' appearance occurs in:
- A. Ellis-van Creveld disease
 - B. Polydactylism
 - C. Arhinencephaly
 - D. All of the above
